In free electrophoresis, cacodylate buffer, *p*H 6·5, μ 0·1, J. C.'s hæmoglobin sample migrated as one sharp peak. In a 1 : 1 mixture of this sample with one from a patient with sickle-cell anæmia there developed two poorly separated components with 63 per cent in the leading one. This electrophoretic behaviour is similar to that previously observed for hæmoglobin *AP* ; in contrast, Stanleyville I moves like *S* in this method.

In electrophoresis in agar gel, citrate buffer, *p*H 6·0 (ref. 8), J. C.'s hæmoglobin sample moved like hæmoglobin *A* ; however, when large amounts of sample were applied, to the extent of 'overloading', there were two components, like *A* and *G* respectively. In quantitative estimations of this sample in starch block electrophoresis, veronal buffer, *p*H 8·6, the percentage of hæmoglobin *A* and of the variant were approximately equal, and that of hæmoglobin A_2 was 1 per cent or less. In the method of alkali denaturation[9], the *F* hæmoglobin value was 1·5 per cent. Unfortunately, no other members of J. C.'s family were available for study.

In summary, a new hæmoglobin variant, appearing together with hæmoglobin *A*, has been found in a Chinese woman living in Honolulu. It was not accompanied by any distinctive clinical or hæmatological findings. This variant resembles types *L*, *P* and Stanleyville I in zone electrophoresis, veronal buffer, *p*H 8·6. It differs from *L* and Stanleyville I in free electrophoresis, cacodylate buffer, *p*H 6·5, μ 0·1, in which method, like hæmoglobin *P*, it does not separate from *A*. It differs from hæmoglobin *P* (and from *L*) in chromatography on 'Amberlite *IRC* 50', in which it resembles (but is slightly faster than) Stanleyville I. It is suggested that this variant be provisionally designated the 'Honolulu type'.

The Gm^a Factor in Japanese

A NUMBER of blood group antigens in addition to hair, eye, and skin colours, the shape of teeth, fingerprints and palm-patterns, ear wax, etc., are used as markers in anthropological research.

Grubb[1] showed that certain human sera when added to the serum of certain rheumatoid arthritis patients will inhibit the agglutination of group $O\ Rh_0(D)$ positive cells sensitized with selected incomplete anti-$Rh_0(D)$ antibody. The human sera having a factor inhibiting the agglutinating activity of rheumatoid arthritis serum were named $Gm(a+)$ and others which do not, $Gm(a-)$. It is believed that the *Gm* factor exists in the γ-globulin fraction.

The studies of the Gm^a factor have been made by various workers and the frequency of $Gm(a+)$ individuals among the white population was about 40–60 per cent. However, Grubb *et al.*[2] recognized 95 per cent of 74 Eskimos to be $Gm(a+)$, Moullec *et al.*[3] reported that all of 500 African Negroes were $Gm(a+)$, Steinberg *et al.*[4] found 98 per cent of 98 American Negroes to be $Gm(a+)$, and Steinberg *et al.*[5] observed that all of 89 American Indians were $Gm(a+)$.

Since it was already well known that the blood-group frequencies of Japanese vary from those of other populations[6,7] it seemed possible that the distribution of the Gm^a factor might also manifest a detectable deviation.

We tested for the Gm^a factor employing rheumatoid arthritis serum, $Gm(a+)$ and $Gm(a-)$ control sera obtained through the courtesy of Dr. R. Grubb, Bacteriological Institute, Lund, Sweden, together with two anti-$Rh_0(D)$ sera selected for their suitability from the specimens which had been stored by one of us (M. Y.) at the Blood Typing Laboratory and Rh Center, Tokyo Medical and Dental University. Later, we received a suitable anti-$Rh_0(D)$ serum from Dr. A. Eyquem, Pasteur Institute, France.

The agglutination–inhibition test (Gm^a grouping) was carried out according to the method of Grubb and Laurell. The tests were performed on 816 normal human sera with the following results: Only 2 (1·0 per cent) of 200 random blood donors in Tokyo and 13 (2·1 per cent) out of 616 blood donors in Kumamoto were found to be $Gm(a-)$. Conversely, we found approximately 98–99 per cent of these sera to be $Gm(a+)$ and the serum factor to be inherited as a dominant Mendelian character (Table 1). In addition, a study was carried out on 34 families whose progeny included identical twins. The test was performed only on the sera of the parents and the twins for a total of 136 tests. Five individuals were found to be $Gm(a-)$. This included 1 parent from each of 4 families and 1 twin from one of these 4 families. Gm^a serum grouping together with other genetic investigations are still being conducted on the family in which one of the identical twins and one of the parents were $Gm(a-)$.

Table 1. THE Gm^a FACTOR IN JAPANESE

	Gm^a factor	
No. tested	$Gm(a+)$ (per cent)	$Gm(a-)$ (per cent)
816	801 (98·13)	15 (1·87)
136*	131 (96·32)	5† (3·68)

* From family study on twins (34 families).
† In four families.

As new blood groups are found and their frequencies determined, it seems probable that additional racial differences will be noted in their distribution. The Gm^a factor together with Gm^x, Gm^b and *Gm*-like factors should prove also to be useful tools in anthropological research.

The γ-Globulin, Gm^{ab}, in Nigerians

THE γ-globulin (*Gm*) genetic polymorphism, first described by Grubb[1], exhibits considerable geographical variation. Steinberg, Boyer and Stauffer[2] recently observed a striking excess of the phenotype *Gm* $(a + b +)$ among Negroes in the United States. Accordingly it was suggested that an allele, Gm^{ab}, exists in coloured populations. The allele frequency of Gm^{ab} among 593 Negroes from Maryland and Ohio is 0·690. The difference between this value and unity was taken as an estimate of European genetic admixture in American Negroes. Essential to this estimate was the assumption that Gm^{ab} frequency is nearly 1·00 in native West Africans. Moullec[3] had previously reported that 449 residents of Dakar were all $Gm(a+)$; however, typing of *Gm b* was not then possible and has not since been described in a West African population.

In the present work aliquots of serum or whole blood from 409 native Nigerian blood bank donors was forwarded, by air, from Ibadan to the United States. *Gm a* and *Gm b* were detected in the manner previously described[2].

All individuals were clearly *Gm* $(a+\ b+)$. There is a probability of 0·05 that either Gm^a or Gm^b is present with an allele frequency of 0·05 but was, by chance, omitted from the present survey. The assumption that Gm^{ab} has a frequency of near unity in West Africans is consequently confirmed.

This work was supported in part by United States Public Health Service Grant No. *B*2053 from the National Institute of Neurological Disease and Blindness.

PATHOLOGY

Surface Enamel Magnesium and its Possible Relation to Incidence of Caries

FOLLOWING the semi-empirical administration of a mixture of alkaline phosphate to a group of 200 patients during a period of three years, it has been noticed that the incidence of caries on continuous enamel surfaces has been significantly inhibited at all age-levels. The surface enamel of exfoliated or extracted teeth from these and other patients is being investigated, and the magnesium content has been shown to vary within extremely broad limits.

This magnesium variable has been correlated with caries incidence or inhibition, also with an abrasive or non-abrasive prophylaxis, and finally, with a (possibly) minerally deficient diet or with a minerally enriched diet. The mixed mineral salts supplied were 50 per cent magnesium phosphate, 25 per cent calcium phosphate and a small percentage of potassium, sodium and iron phosphates. They were fluoride-free.

Table 1. Analytical Results, corrected to 0·0050 gm. Sample, Expressed in ml. 0·002 *M* Ethylenediamine Tetraacetic Acid (First Series 29/3/60)

Patient	Age (yr.)	Tooth	Dental status	History	Calcium	Magnesium
P.C. (female)	11	Lower right permanent canine	Non-carious, non-abraded	Magnesium salts, 2 yr., inhibited caries incidence	4·73	0·22

* These teeth were re-washed some months after exfoliation. Surface organic degradation may render magnesium more soluble, hence possible loss in washing.

† Organic charring noted in these samples.

‡ Tooth-paste *C* appears to be highly surface reactive, and uniquely compatible with a surface enamel preservation therapy.

Preliminary chemical analyses, carried out in the Chemistry Department, University of Otago, have indicated that an important role can possibly be assigned to magnesium (phosphate) in the stabilization of chemical, physical and electrokinetic states of the surface enamel calcium. As in all biological assays, the method of analysis has been considered of primary importance, and is reported here in detail.

All teeth, immediately after extraction, were washed and rubbed with cotton wool in distilled water, then air dried at 20° C. for several days. Intact enamel surfaces (bucco-labial and lingual) were subjected to a standardized abridement, a new No. 35 *SSW* carbide inverted cone bur, at approximately 50,000 rev./min. in a rigid handpiece, scoring a light line down the incisal (or occlusal) two-thirds of the surface at an approximate depth of 50–100μ. A series of similar, parallel lines was scarified on the area to be sampled, a measurable evenness of depth being obtained with some certainty after considerable experience. The bur was then moved lightly cross-wise against the intervening ridges, reducing the scored area to a uniform level. The very finely powdered enamel thus produced settled (in a still atmosphere) on a foot square of clean 'Polythene' covered card. This was carefully brushed into a prepared, wide-necked dry glass jar, sealed, and labelled ready for micro-sampling.

After each enamel surface was thus sampled, the bur was cleaned and inspected under a microscope for vane damage. If detected, the bur was discarded. Each sample was subjected to a high magnetic drag to remove any ferric contamination possible in this method. Samples were then submitted to water-bath dehydration for 48 hr. A varying weight of sample was micro-weighed and ashed at the minimum temperature with a drop of sulphuric acid in platinum vessels. The mineral ash was dissolved again successfully by dilute acid re-digestion and water elution into 'Polythene' receptacles, and prepared for a 'double blind' series of titrimetric analyses.

The method of Betz and Noll[1] (for total magnesium–calcium estimation) was modified. A 5-ml. sample was pipetted into a white 'Polythene' beaker. 1 ml. standard $MgSO_4.7H_2O$ (0·001 gm./l.) was added and made up to 50 ml. *p*H was adjusted to 7·0 with a glass electrode *p*H meter. 0·3 ml. freshly made standard buffer (A.R. borax, sodium hydroxide) was added, bringing the *p*H to 10·5. 0·1 mgm. 'Solochrome' indicator (standard preparation) was added and swirled until dissolved. Titration was with 0·002 *M* ethylenediamine tetraacetic acid (disodium) under an automatically condensed light from a single Philips' 8-V. 50-W. lamp through a standard blue filter, giving an intense field of beamed white light (approximately *K* 5,500) on to white filter paper. Blue filter is not critical but the titrating light field, when photographed in daylight 'Kodachrome', should give a normal colour balance, indicating approximately light grading *K* 5,500. Light deterioration became evident only after 15 hr. service. All titrations were carried out in a darkroom, at 20° C. Titration end-point was to the definite discharge of the slightest purple tint, the final cold blue being stable over a period of at least 45 min. Continuous vigorous agitation accompanied a minimum titration time of 3 min., a rigorously standardized procedure.

As a trace of iron sometimes gave the blue colour a greyish tint, a preliminary titration of each sample gave a separate standard for colour comparison, being over-titrated 0·1 ml. to a stable blue. All analyses were double- or triple-checked, and consistent figures were obtained throughout.

Calcium estimation was with 'Calcein' indicator, under similar conditions, according to the method of Socolar and Salach[2].

Table 2. COMPARATIVE SUMMARY, ML. OF 0·002 *M* ETHYLENEDIAMINE TETRAACETIC ACID/5 MGM. ENAMEL

Calcium		Magnesium	
Dietary increment of magnesium salts mixture	Non-salts	Dietary increment of magnesium salts mixture	Non-salts
4·73	4·75	0·22	0·03
4·33	4·60	0·13	0·05
3·65	4·75	0·42	0·19
4·19	4·70	0·49	0·08
4·35	4·42	0·30	0·27
4·13	4·60	0·10	
4·31	4·50	0·28	0·14
3·50		0·30	0·12
Average 4·15	4·61	0·28	0·13

This may be regarded as a first-line, expendable and mobile mineral reserve to save calcium demobilization in the carious process. A more extensive series of further analyses is being carried out in the Chemistry Department, University of Otago, and will support a postgraduate thesis, Dental School, University of Otago.

I am indebted to Prof. W. G. Edwards (now of the Chemistry Department, Royal University of Malta) for his assistance and guidance in the analytical work involved. Thanks are due to Mr. Hughes, Physics Department, University of Otago, for micro-measurements of the depths of enamel surface.

Mechanism of Antigen Transformation of Transplantable Rat Tumour

In earlier investigations we have established that in the case of temporary heterotransplantation of Guérin's rat epithelioma to mice, a change occurs in its antigen structure[1]. The change consists in the appearance of an additional antigen, not found in the original tumour. The presence of this antigen could be demonstrated by various methods as late as 5 years after the modification induced by heterotransplantation, although the tumour had been passaged all this time exclusively on rats[2,3].

The question arose as to the mechanism by which this durable modification of the antigen structure of the rat tumour occurs in the course of temporary passaging on mice. The correctness of various hypotheses was tested experimentally and the mechanism of genetic transformation appeared to be most probable. This is shown by the following experiments carried out on the same principle as the classical experiments of Griffith[4] with pneumococci.

A suspension of rat epithelioma cells was prepared and mixed with homogenated mouse lymphocytes. These cells from mouse lymphatic nodes were mechanically disrupted in a glass mortar and suspended in physiological saline in the ratio 1 : 1. This homogenate was mixed with the rat tumour cell suspension in a volume ratio of 1 : 2, 1 : 3 or 1 : 4 and injected subcutaneously to rats.

At the site of injection, inflammation appeared; this subsided after several days and the tumour developed. From such a tumour a new cell suspension was prepared and mixed with the mouse lymphocyte homogenate as before. In this manner a new sub-line of the tumour was obtained which was further passaged on rats in the routine way. The scheme in Fig. 1 shows the branching sub-lines U_I, U_{II}, U_{III} and W_I, W_{II}, W_{III} of the original line of Guérin epithelioma. In successive passages, the antigen structure of the tumour was tested by the method of antibody absorption and complement fixation and referred to the original tumour as well as to the following control antigens: (1) extract of parenchymal organs of normal rats and mice, (2) rat necrotic tissue obtained by intramuscular injection of 0·1 *N* silver nitrate. Several series of these experiments were carried out. In series W_I, W_{II}, W_{III} the Guérin tumour cell suspension was mixed with homogenated lymphocytes of normal *C57BL* mice; in series U_I, U_{II}, U_{III} the lymphocytes of actively immunized mice *C57BL* with Guérin epithelioma were used.

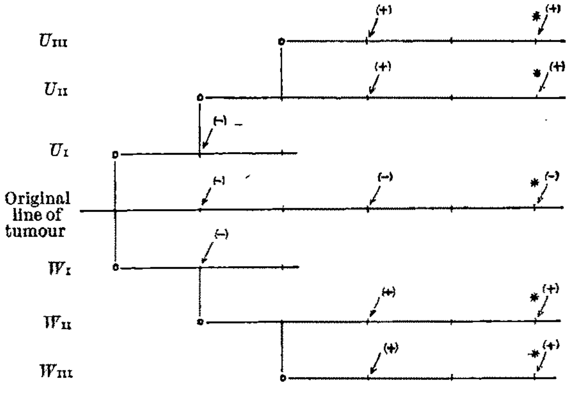

Fig. 1. Scheme of original line and sub-lines of Guérin's epithelioma. Sub-lines W_I, W_{II}, W_{III} produced by mixing the suspension of original Guérin tumour cells with ground lymphocytes of normal mice. In a similar manner the sub-lines U_I, U_{II} U_{III} were obtained using lymphocytes of mice actively immunized against the Guérin tumour. o, Time of mixing the tumour cells with mouse lymphocytes. The arrows indicate the time of serological examination of the tumours. + and −, presence and absence, respectively, of the additional antigen. Asterisks denote complement fixation tests shown in Table 1. Each section of the line marks a monthly period in which the tumour was passaged

In every phase of the experiment the tumour was examined bacteriologically, and only sterile tumour was taken for antigen structure tests. Such control excludes the possibility of contamination of the Guérin tumour by bacterial antigens.

It was established, as a result of these experiments, that in some rat tumours, under the influence of mouse lymphocyte homogenate, an additional antigen appeared. The latter subsisted in the tumour for 3–4 months in spite of repeated passaging. For illustration a record of one of our serological tests is given (Table 1). No difference was observed between the sub-lines obtained with lymphocytes of normal and immunized mice.

Table 1

Antigens	Dilutions of serum				
	1/16	1/32	1/64	1/128	1/256
$T_8\ W_{\rm II}$	+ + +	+ + +	+	±	–
$T_8\ U_{\rm II}$	+ + +	+ + +	+ + +	–	–
$T_8\ W_{\rm III}$	+ + +	+ + +	+ +	+	–
$T_8\ U_{\rm III}$	+ + +	+ + +	+ + +	±	–
$T_8\ C$	+ + +	+ + +	+ + +	+	–
T_8 (original tumour)	+ +	±	–	–	–
From mice (*C57BL*)	–	–	–	–	–
From rat	+ +	–	–	–	–
Necrobiotic antigen	+ +	±	–	–	–

Results of complement fixation with specific antiserum *T8C* adsorbed on original tumour *T8* particles. This antiserum was used in all experiments as standard. Antiserum *T8C* was prepared by immunizing rabbits with the sub-line *T8C* of the Guérin tumour obtained 5 years ago by heterotransplantation on mice (ref. 1).

We believe that in our experiments the disrupted mouse lymphocytes decomposed to smaller particles in the rat organism during inflammation and were possibly incorporated into the genome of the tumour cell.

This enrichment of the tumour cell genome probably brought about the synthesis of an additional cytoplasmic protein manifesting itself as an additional antigen.

The experiments seem to indicate that the mechanism of genetic transformation may be responsible for the antigen modifications occurring in the Guérin tumour. It would be desirable to establish whether a foreign, purified deoxyribonucleic acid molecule will produce a similar transformation. Further experiments in this direction are in progress in our laboratory and the preliminary results seem to confirm this possibility.

In our opinion the mechanism of genetic transformation of somatic cells would be easier to demonstrate if the experiments were performed on anaplastic and poorly differentiated tumour cells and if nucleic acid from normal and highly differentiated cells were used as transforming agent. Under these conditions any property of a highly differentiated cell transmitted to the anaplastic tumour cell can serve as marker.

ANATOMY

Use of Tritiated Thymidine for the Study of the Origin of the Osteoclast

The origin of the osteoclast has been in question for about a century. So far back as 1873, Kölliker[1] maintained that the osteoclast was formed by the fusion of precursor cells and that these precursor cells were osteoblasts. However, Kölliker's work lacked convincing proof, and as a result, numerous theories appeared concerning the origin of the osteoclast. These theories were based largely on morphological studies of metaphyseal osteoclasts. The presence of numerous cell types at this site makes observation of cellular transitions difficult. In order to circumvent this difficulty, we have examined the distal periosteum of young mouse femora, where numerous osteoclasts appear. The cellular complement of the osteogenic layer of the periosteum generally consists of pre-osteoblasts and osteoblasts.

In a previous communication[2], tritiated thymidine was used to label osteoclasts, which were not seen 1 hr. following administration of the isotope (Fig. 1). Numerous osteogenic cells showed uptake of thymidine, but labelled osteoblasts were found less frequently. The actual number of labelled osteoblasts observed was so few that the chance of finding a labelled osteoclast was exceedingly small. In addition, the observations were made 1 hr. following injection of tritiated thymidine. This period of time is too short to allow labelled pre-osteoblasts in DNA synthesis to pass through the post-synthetic and mitotic phases, undergo transformation into osteoblasts, and in turn fuse to form osteoblasts.

The present work has extended the period of observation to 25 days following isotope administration, in order to allow sufficient time for labelled cells to divide, thereby increasing the actual number of labelled periosteal osteoblasts, which increases the chances of demonstrating labelled osteoclasts.

A subcutaneous injection of 0·5 μc. of tritiated thymidine per gm. body-weight was given to 24 four-

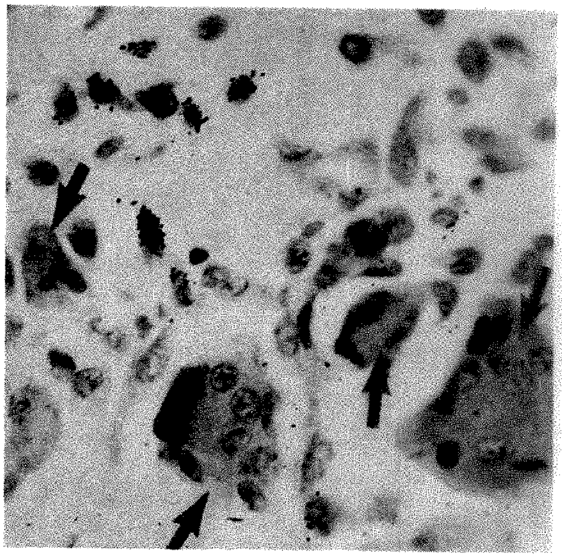

Fig. 1. Autoradiograph of mouse femoral periosteum at the perichondrial region near the distal epiphysis of the femur. Several periosteal cells are labelled with tritiated thymidine 1 hr. after administration of the isotope. The osteoclasts are unlabelled. (Oil immersion, × 470)

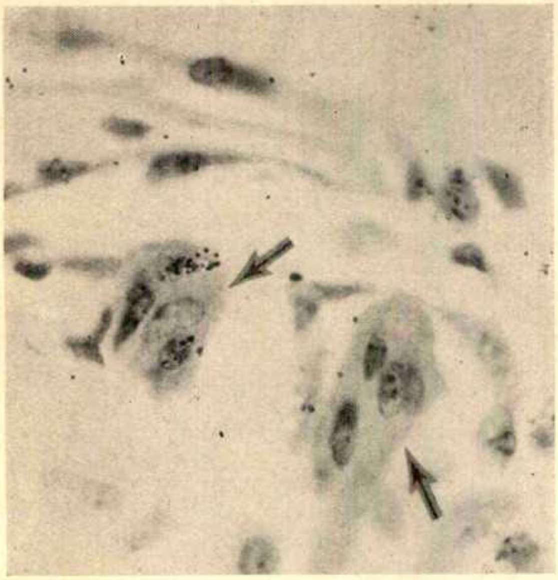

Fig. 2. Autoradiograph of periosteal osteoclasts labelled with tritiated thymidine and observed 36 hr. following the administration of the isotope. (Oil immersion, × 470)

week-old female mice of a *BNL* Swiss albino strain. The animals were killed at various intervals, ranging from 5 min. to 25 days after administration of the isotope. Femora were fixed for 3 hr. in acetic/alcohol (1 : 3) followed by an additional fixation for 24 hr. in formolsaline and 24 hr. of washing. Bone samples were decalcified in a 10 per cent solution of versene. Paraffin blocks were prepared, sections cut at 5μ and autoradiographs prepared with Kodak-NTB_3 liquid emulsion. Preparations were exposed for 20 days, after which time they were developed and stained with hæmatoxylin and eosin.

Autoradiographs revealed labelling of periosteal osteogenic cells throughout the entire period. With increasing time following injection of the isotope, additional osteoblasts were seen to be labelled. Labelled osteoclasts were observed for the first time at 36 hr. post injection (Fig. 2). Labelling was seen in one, and less frequently two, nuclei. The remaining nuclear complement was unlabelled. No osteoclastic labelling was observed 10 days following isotope administration.

A previous report[3] has presented direct cytological and cytochemical evidence for the formation of osteoclasts from osteoblasts. It was also shown that osteoclasts do not arise as a consequence of nuclear division, since none was labelled initially. Considering that osteoclasts are being continually renewed, the frequency of labelled osteoclasts depends on the available number of labelled precursor cells as well as other factors. Labelled osteoclasts were not encountered in the present work until an increase in the labelled population of periosteal osteoblasts had occurred. The results show, therefore, that osteoblasts serve as the precursor cells for osteoclasts, and that their polynucleated character arises from the fusion of osteoblasts and not from the repeated division of the osteoclastic nucleus.

This investigation was supported by the U.S. Atomic Energy Commission.

HISTOLOGY

Influence of Oxygen Concentration and Mechanical Factors on Differentiation of Connective Tissues *in vitro*

MARCHAND[1] postulated that osteoblasts may differentiate from mesenchymal cells. Recently, it was observed that a strain of cells, derived from adult skeletal muscle, elaborated in tissue culture a substance that appeared to be chondro-osteoid[2]. Since the factors responsible for this cell behaviour were unknown, investigation of the effects of varying mechanical and nutritional factors on a reproducible *in vitro* system of osteogenesis was made. Hanging-drop, Maximov double cover-slip cultures were established from 20-day-old chick embryo tibial cortex and were maintained as described by Fell[3].

Effect of compaction and high oxygen. In one experiment, the cultures were excised periodically from the clot; gassed with a mixture of 35 per cent oxygen, 60 per cent nitrogen and 5 per cent carbon dioxide, and transferred to a new clot. As the cell mass was cut free it usually contracted, thus crowding the increasing population into a more compact state. Cultures were killed on the fourteenth day by fixation in cold 80 per cent alcohol, and serial paraffin sections prepared. Bone was found in 100 per cent of these specimens. In most, a dome-shaped plaque of osseous tissue covered the outer portions. However, in some preparations, where contraction of the culture had been uneven, the bony mass was distorted. The tissue contained numerous young osteocytes, embedded in a

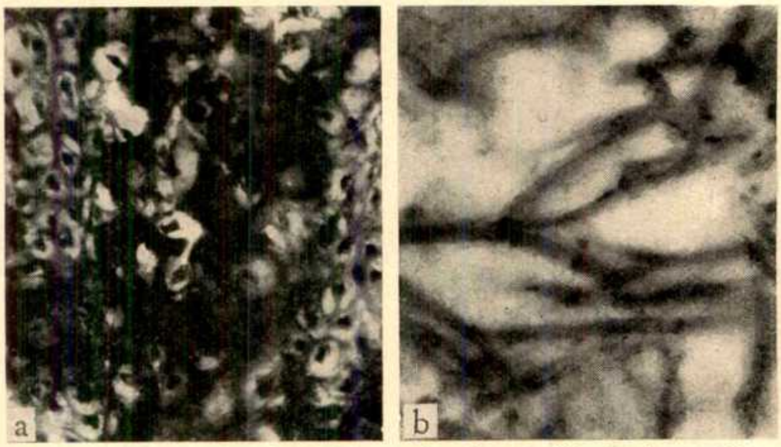

Fig. 1. *a*, Dark areas are heavily calcified, young bone (hæmatoxylin and eosin, × *c*. 350); *b*, electron micrograph of bony area—note 'seeded' collagen (× *c*. 36,000)

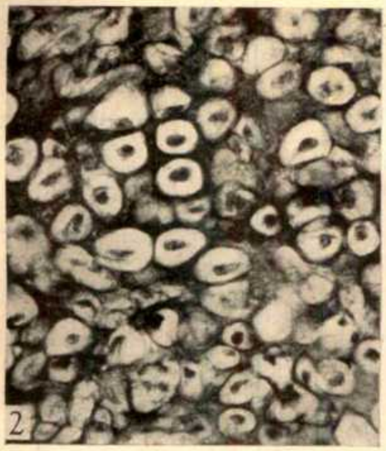

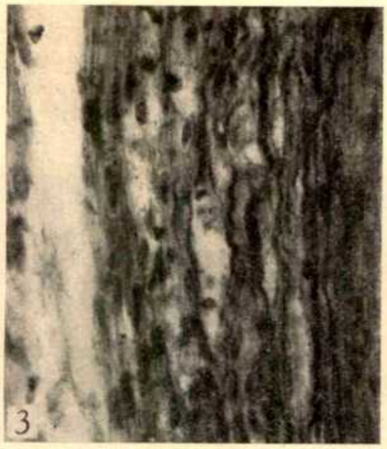

Fig. 2. Dark areas about cells are intensely metachromatic (thionine, × c. 350)

Fig. 3. Oriented wavy collagen fibres with interspersed 'fibrocytes' (Van Gieson, × c. 487)

matrix which appeared to be predominantly collagenous, when stained by hæmatoxylin and eosin, the van Gieson or Masson trichrome techniques (Fig. 1*a*). When this matrix was stained with thionine, alcian blue or toluidine blue at *p*H 2, 4 and 6, metachromasia was not demonstrable. All osseous areas were heavily calcified, when judged by the reaction with hæmatoxylin, alizarin red *S* and von Kossa stains. Electron-microscopic examination of typical bony areas in these cultures was kindly performed by Dr. James Harkin of the Hospital for Special Surgery and showed collagen fibrils. Many of these fibrils were studded with discrete, electron-dense areas which had an average 640 Å. repeat pattern (nucleation centres or crystal seeds) (Fig. 1*b*). In many aspects, the picture resembled that obtained by Fitton-Jackson[4] in her examination of developing, embryonic chick bone. Very dense areas, believed to be similar to calcification fronts described by Robinson[5], were seen. The deeper portions of these cultures appeared to be cartilage when examined by the light and electron microscope.

Effect of compaction and low oxygen. In a second experiment, the cultures were grown as those just described, except that the oxygen concentration in the gassing mixture was lowered from 35 to 5 per cent, while the nitrogen was raised from 60 to 90 per cent. Under these conditions cells proliferated and migrated well, but no bone was observed. However, hyaline and fibrocartilage were found at the periphery and in all cultures the central areas were less well differentiated. Bundles of collagen, interspersed between relatively small chondrocytes in the fibrocartilage, were stained by the van Gieson technique and deep blue with the Masson trichrome technique. In these areas, no metachromasia was observed. However, in areas having the appearance of hyaline cartilage (Fig. 2), the plumper chondrocytes were surrounded by metachromatic, non-fibrillar matrix. No evidence of calcification was seen in these cultures.

Effect of stretching and high oxygen. In the third experiment, the cultures were prevented from contracting by stretching them over progressively larger silicone rods during the growth period. The other conditions were the same as in the first experiment. No cartilage, bone or calcification was found in cultures that were stretched uniformly. The tissue appeared more like young, growing tendon or fascia. Cells, which resembled mature, elongated fibrocytes, were interspersed between thick, parallel bundles of collagen (Fig. 3). No metachromasia was found in these sections. In some cultures uniform tension in the tissue ring could not be maintained and portions of it contracted. Bony masses with cartilagenous centres were found in the compacted areas, while oriented, fibrous tissue was found immediately adjacent in areas where tension was maintained.

These experiments demonstrate that mechanical (stretching and compacting the cell mass) and nutritional (variations in oxygen) factors, acting in concert, can determine the type of connective tissue that differentiates in a culture of cells arising from bone. Although the mechanisms by which the different tissues were produced are not known, at least two interpretations are possible. First, the conditions in culture may favour one cell-type in a mixed population so that it proliferates and produces a specific extracellular matrix. Second, the conditions in culture may determine the secretory pattern of the cell so that it produces different extracellular matrices in response to different environmental factors. In any event, the results appear to agree with the Maximov concept[6] that certain 'fibroblasts' are pleuripotential and may differentiate in a number of ways to produce the various connective tissues.

BIOLOGY

Efferent Innervation of Mammalian Muscle-spindles

MAMMALIAN intrafusal muscle fibres are innervated by the small γ-efferent fibres of Leksell[1], which have nerve-trunk diameters of 2–8μ. Fibre size histograms of the intramuscular diameters of both intra- and extra-fusal efferents in fresh and gold chloride preparations show that, while both share the same peak at 3·5μ, about 30 per cent of the intrafusal efferents lie outside the extrafusal range at 4–6μ (ref. 2). These larger fibres have been reported in various descriptions of spindle innervation[3–6]; in cat rectus femoris, they take part in the innervation of about one-third of the spindles present (Adal and Barker, unpublished). They could be members of either the 2–8μ γ-group, or the 8–18μ α-group, which have not undergone such extensive branching as the majority of their fellows. The work of Granit, Pompeiano, and Waltman[7] on the α-activation of cat spindles directs attention to the possibility that some members of the α-group may branch so as to innervate both intra- and extrafusal muscle fibres. Such a claim has been made by Weiss and Dutil[8], Cilimbaris[4], Wilkinson[9], Denny-Brown[10], and, more recently, Häggqvist[11]. Wilkinson (echidna spindles) and Häggqvist (monkey spindles) have each published a photograph purporting to show such innervation, but they are unconvincing and open to alternative interpretation. We have examined fifty gold chloride preparations of echidna (*Tachyglossus aculeatus*) spindles without finding instances of collaterals from α-fibres innervating intrafusal muscle fibres, and examination of more than two thousand gold chloride cat spindles, accumulated during work on various aspects of this receptor, has also failed to yield any instance of such innervation. Examination of bat, monkey, opossum, rabbit, and rat spindles has also proved negative in this respect. When apparent examples of such branching have been encountered, closer examination and further tracing has always shown the presence of two discrete fibres; in such instances, the two fibres are usually superimposed one above the other during their course before diverging, so as to give the impression of a single fibre branching into two. Similar instances occur with afferent fibres, and have led to claims[8,12–14] of a single fibre branching so as to terminate in a spindle primary ending and a nearby tendon-organ. If branches of α-efferent fibres do innervate the mammalian spindle, we are of the opinion that the collaterals must originate some distance away from the receptor, either within the muscle nerve or within intramuscular nerve trunks. However, experimental evidence for the innervation of the spindle by α-efferents is conflicting[15], and it seems, on balance, more probable that in mammalian muscle there are discrete intrafusal (γ) and extrafusal (α) efferent systems.

These observations were made during the course of work supported by research grant *B*-1806 from the National Institute of Neurological Diseases and Blindness, U.S. Public Health Service.

Glycogen of Mactra

GLYCOGENS, branched chain polymers of glucose containing α-1,4-glycoside bonds in the main chains and α-1,6-glycoside bonds at the branch points, have been identified in the tissues of all animals thus far examined[1]. These polymers are made up of a single kind of sub-unit bonded together by a single type of bond and thus only relatively small differences in the glycogens from different species have been found. The most important difference is in the average chain-length of the molecule, which is inversely related to its degree of branching. This measurement describes quite well the main features of the glycogen molecule, and is therefore of interest to the student of comparative biochemistry. The glycogen of *Mactra* had not been previously characterized; and this communication describes some of the properties of the compound isolated from this pelecypod mollusc.

Specimens of *M. fragilis* obtained from the Supply Department of the Marine Biological Laboratory were used for isolation of glycogen by Pflüger's method: muscle (25·0 gm.) and combined viscera (30·3 gm.) of the animals were digested separately in 50 ml. each of 30 per cent potassium hydroxide on a steam bath. After 30 min. of digestion, homogeneous solutions resulted, and they were cooled and 5 ml. of 0·2 per cent sodium sulphate and 125 ml. of 95 per cent ethanol were added and mixed. The solutions were brought just to the boiling point, and then were chilled and allowed to stand overnight at 3° C. The solutions were centrifuged for 10 min. at 5,000*g* and the resulting supernatant fluid was discarded. The residues were dispersed in 30 ml. distilled water, 1·5 vol. of ethanol were added, and the precipitation was carried out as before. After the muscle glycogen had been precipitated in this way three times and the viscera glycogen four times, the residues were a light tan colour. Following the last precipitation, the glycogen was collected on a sintered glass funnel with gentle suction, and the product was washed on the filter with a little acetone to remove the last traces of a coloured impurity. The resulting white powder was dried *in vacuo* over calcium chloride to constant weight, and was used for the analysis described here.

The ash content of the material was determined by ignition. Samples of the glycogens were hydrolysed in 5 *N* sulphuric acid at 100° C. for 30 min., the solutions were neutralized with dilute sodium hydroxide, and aliquots were taken for reducing sugar analysis and glucose determination by the specific enzymatic reaction with glucose oxidase. The average chain-length was determined exactly as described by Fales[2].

The results of the various analyses are shown in Table 1. In accordance with the experience of other investigators, a significant inorganic residue remains in the glycogen preparations even after repeated alcohol precipitation. The 80 per cent acetic acid precipitation procedure used by Baldwin and Bell for the removal of these salts[3] was not used in the present investigations because of the known lability of the acetal bond in acid. Within the limits of error of the copper reduction method used, all the organic material in the preparations is accounted for as hexose in diglycoside linkage, assuming that these hexoses have a reducing power equivalent to that of glucose. According to the results of the less-precise glucose oxidase analysis, all the hexose is accounted for by glucose itself. Thus the experimental data are consistent with the view that *Mactra* glycogen consists entirely of D-glucose polymerized into chains by glucoside bonds.

Table 1. ANALYSES OF GLYCOGEN FROM *M. fragilis*

	Muscle	Viscera
Yield (gm. per 100 gm. wet tissue)	2·4	2·0
Ash (per cent)	3·1	1·7
Reducing substances (as diglucoside) (per cent)	94·8	96·9
Glucose by glucose oxidase (as diglucoside) (per cent)	108·5	93·3
Average chain-length	13·3	7·3

The result of the average chain-length determination on muscle glycogen is similar to that obtained by Fales[2] with oyster glycogen, and is in the range reported by other investigators who used somewhat different methods of periodate oxidation on glycogen from a variety of species[1,4]. The viscera glycogen of this animal has a considerably shorter average chain-length. The observations do not provide any information about the location in the glucose units of the glycoside bonds, but it may be assumed that they are the customary α-1,4-glycoside bonds with α-1,6-bonds at the branch points.

It is evident that more data on the structure of glycogens from a variety of species must be assembled before any generalizations can be made. Particular emphasis should probably be placed on the examination of material from the most primitive forms available.

These investigations were supported in part by grants from the Association for the Aid to Crippled Children, the Charles A. and Marjorie King Fund, and the National Institutes of Health, U.S. Public Health Service.

Absence of Chitinase in *Limnoria*

THE question of the presence or absence of a chitinase in *Limnoria* is of interest for two reasons. First, if a chitinase were present, chitin could serve as a principal nitrogen source. Ray and Julian[1] and Ray[2] have shown that *Limnoria*, which eats wood, can break down cellulose to glucose, and can therefore utilize wood as a source of energy. However, it is not yet known what source of nitrogen *Limnoria* utilizes because wood contains so little. One possible nitrogen source is chitin, present in cell walls of fungi growing in wood and often eaten with the wood[3], and present in the animal's exuviæ, which it may eat.

This question is also of interest for another reason. Since both cellulose and chitin are *B*-glucosides, it is possible that the same enzyme could hydrolyse both ; that is, the cellulase found by Ray in *Limnoria* could be a general *B*-glucosidase capable of splitting chitin also.

In an attempt to answer this question, 20, 30, 40 and 60 mgm. of powdered chitin prepared from *Loligo* pens were incubated at 25° and 30° C. for 2–12 days with 0·2 ml. of *Limnoria* enzyme solution and 0–1·0 ml. of McIlvaine's buffer, *p*H 5·6. The enzyme solution was prepared by the method described by Ray[4]. The midgut diverticula of approximately 60 animals were used to make each 0·2 ml. of enzyme solution. At the end of the incubation periods the solutions were tested by paper partition chromatography to determine whether acetylglucosamine or any other reducing sugar had been obtained from the chitin. The tests were all negative, although control solutions of carboxymethyl-cellulose plus enzyme incubated at the same times under the same conditions did contain reducing sugars (mostly glucose) at the end of the incubation periods.

In another experiment, suspensions of chitosan, suspensions of partially hydrolysed chitin, and solutions of carboxymethyl-cellulose were incubated at 30° C. for 7 days with 0·2 ml. of enzyme solution. Each tube contained 20 mgm. of substrate suspended or dissolved in 1 ml. of McIlvaine's buffer at *p*H 5·6. The chitosan was prepared from *Loligo* chitin by treating with hot saturated potassium hydroxide, washing, dissolving in acetic acid, and dialysing against buffer. At the end of the incubation period the solutions were treated as above. No reducing sugar was found, although the control solution of carboxymethyl-cellulose plus enzyme did contain reducing sugar.

Apparently the cellulase present in the midgut diverticula of *Limnoria* is not a general *B*-glucosidase capable of hydrolysing chitin. It is still possible that *Limnoria* produces a chitinase inactive under the conditions tested or that some other portion of the gut produces a chitinase. However, this seems unlikely. Probably, *Limnoria* is not able to utilize chitin as a source of nitrogen.

This work was carried out under contract with the Office of Naval Research and in co-operation with Dr. D. L. Ray.

Comparative Chemistry and the Relationship of the Hamamelidaceae

IN many of the more recent systems of classification, the Hamamelidaceae have been given a central position, several authors believing that they have been derived from rosalian or magnolialian ancestors, and that they, in turn, have given rise to some of the amentiferous families. Although the family is usually included in the Rosales, a number of systematists have assigned it to the order Hamamelidales.

In investigating the relationships of the Hamamelidaceae and those families which have been included in an order Hamamelidales, as well as those of the Rosaceae and some of the amentiferous families, chemical characters have been used.

The chemical characters of the Hamamelidaceae, based on testing twenty-five species representing twelve genera, are the following[1] : (*a*) they are positive to the hydrochloric acid methanol test ; (*b*) they are positive to the leuco-anthocyanin test ;

(*c*) they give a red reaction to the 'syringin' test ; (*d*) they give a magenta spot with Ehrlich's reagent ; (*e*) they are negative to the hydrogen cyanide test ; (*f*) they are negative to the 'juglone' test ; (*g*) they show no fluorescence in 'juglone' tests ; (*h*) they lack raphides ; (*i*) they lack detectable amounts of glucitol and sedoheptulose ; (*j*) they give the '*Oxalis* reaction' to the cigarette and hot-water tests.

These characters have been compared with those of representatives of the other families tested. Other things being equal, it is assumed that those families which show the closest chemical correspondences are the most closely related.

Of twenty families (Myrothamnaceae, Platanaceae, Cunoniaceae, Eupteleaceae, Stachyuraceae, Eucommiaceae, Cercidiphyllaceae, Trochodendraceae, Buxaceae, Daphniphyllaceae, Coriariaceae, Pittosporaceae, Hydrangeaceae, Saxifragaceae, Bruniaceae, Tetracentraceae, Altingiaceae, Byblidaceae, Podostemaceae and Hydrostachyaceae) which have been included in an order Hamamelidales, representatives of the first fourteen have been tested.

On the basis of results of these tests, one may propose an order Hamamelidales including the Hamamelidaceae, Platanaceae, Myrothamnaceae, and perhaps the Cunoniaceae. This suggestion is based on preliminary work only, but at present there is no chemical evidence against, and much for, such a grouping.

If the sub-family Chrysobalanoideae be excluded, the Rosaceae form a homogeneous group, distinguished by the occurrence of glucitol and cyanogenetic compounds. The chemical evidence indicates that the Rosaceae and the Hamamelidaceae differ sufficiently to make it unlikely that they should be included in the same order ; however, there is no evidence against the view that the Hamamelidaceae are descended from rosalian ancestors.

Representatives of eleven amentiferous families (Garryaceae, Leitneriaceae, Casuarinaceae, Salicaceae, Myricaceae, Juglandaceae, Butulaceae, Fagaceae, Urticaceae, Ulmaceae and Moraceae) have been tested. The chemical evidence indicates that if the Garryaceae, Leitneriaceae and Juglandaceae be excluded, these families form a natural group. There is no evidence against the view that these families have been derived from hamamelidalian ancestors.

BACTERIOLOGY

Bacterial Polyglycerophosphate

In a previous communication the presence in streptococcal culture supernatants of four serologically distinct red-cell sensitizing antigens was described[1]. One of these antigens, Hickey, which was found to be of wide distribution among the Gram-positive cocci, is almost certainly identical with the non-species specific antigen described by Rantz, Randall and Zuckermann[2]. The distribution of this antigen has been observed to resemble closely that reported by McCarty[3] for a glycerophosphate polymer isolated from various bacterial species, and it seemed possible that we were in fact dealing with the same compound. The polymer as isolated by McCarty had serological properties in that it was precipitated by certain streptococcal antisera—precipitation being inhibited markedly by synthetic polyglycerophosphate prepared by Dr. A. M. Michelson[4]. Glycerophosphate polymers have also been isolated from bacteria by Mitchell and Moyle[5] and by Baddiley *et al.*[6] ; but in neither of these cases were they investigated serologically.

Two samples of synthetic polyglycerophosphate (calcium salts) with average chain-lengths of 6 and 10–15 units respectively have generously been made available by Dr. Michelson, and their capacity to inhibit hæmagglutination by the Hickey serum has now been investigated. These tests were carried out with human Group *O* red cells treated for 2 hr. at 37° C. with a digest broth supernatant of the Hickey strain of *Streptococcus pyogenes*. Both compounds had marked hæmagglutination-inhibiting capacity—in the test system employed showing appreciable inhibitory activity in a concentration of 30 μgm. per ml. No inhibition of hæmagglutination by antisera specific for the other three streptococcal sensitizing antigens described was observed. (These latter tests were carried out with the 6-unit compound). Neither polymer was capable of precipitating with the Hickey antiserum nor of sensitizing red cells to hæmagglutination by it. Inhibition was also demonstrated with a mixture of α- and β-glycerophosphates (calcium salts, approx. 45 per cent α-) and with β-glycerophosphate (sodium salt). The inhibitory activity of the latter compounds was, however, relatively slight—that of the α-glycerophosphate mixture being of the order of one-fortieth, and that of β-glycerophosphate one two-hundredth, of that of the polymers.

These results would indicate, therefore, that the serologically active component of the Hickey sensitizing antigen is, like that of McCarty's precipitating antigen, a glycerophosphate polymer the activity of which is probably due to α-glycerophosphate residues. They suggest also the possibility that the serological specificity of other bacterial red-cell sensitizing antigens might also be due to polyol phosphate components.

I wish to express my gratitude to the Medical Research Council of Ireland for financial support.

[2] Waksman, A. S., *The Actinomycetes*, 2 (Williams and Wilkins Co., Baltimore, Vol. 2, in preparation).

Three groups of strains could be distinguished: strains with abundant deep-brown pigment on both media, strains with pigment production only on plain gelatin, and strains without pigment production on either medium. Because the production of melanoid pigments plays an important part in *Streptomyces* classification, it was decided to study this phenomenon further. This communication deals with some preliminary experiments on this subject. The experimental results are listed in Tables 1 and 2. (The results in Tables 1 and 2 were obtained in two different experiments and are not strictly comparable because the gelatin concentration was slightly changed.) The presence of peptone (0·5 per cent) in the media had no influence on the production of soluble melanoid pigments.

The effect of glucose on pigment production depends to a certain extent on its concentration and whether it is sterilized together with gelatin or separately. It was found that 0·5 per cent glucose has no effect; 1·0 and 2·0 per cent glucose exhibits a pronounced inhibitory effect on pigment production when sterilized together with the gelatin, but no or only slight inhibition when sterilized separately. 5 per cent glucose inhibits pigment production in all 'positive' strains when sterilized together with gelatin, and in some of them when sterilized separately.

VIROLOGY

An Immunizing Antigen from Rabbit-Pox and Vaccinia Viruses

It is well known that infection with vaccinia or one of the other animal pox viruses produces a high degree of immunity, associated with the appearance of neutralizing antibody in the serum. Recently, Collier, McClean and Vallet[1] have shown that neutralizing antibody can also be elicited by vaccinia virus inactivated by ultra-violet light. But attempts to obtain immunizing material free from virus particles have had little success[2,3]. This communication describes a virus-free immunizing antigen extracted from tissues infected with rabbit-pox or vaccinia viruses. The injection of this soluble material into rabbits resulted in the formation of sera with a neutralizing antibody titre against vaccinia comparable with that found in animals convalescent from rabbit-pox infection.

Rabbit-pox virus (Utrecht strain) was grown for 24 hr. in monolayer cultures of *ERK*1 cells[4]. The infected cells were concentrated to 4×10^7 per ml., and disrupted by ultrasonic vibration. Virus was removed from the suspension by centrifugation and filtration, to give a cell extract which was non-infective when inoculated on to the chorioallantoic membrane of 12-day eggs.

Incubation of the cell extract with a high dilution of hyperimmune rabbit-pox antiserum resulted in disappearance of the neutralizing activity. The substance responsible for this reaction was termed the 'serum-blocking antigen'. A method was developed for the quantitative determination of the serum-blocking activity of a preparation, and this was used to study the properties of the antigen. The serum-blocking antigen was non-dialysable; but it was smaller than the virus, passing a collodion membrane of 330 mμ av. pore diam., and was not sedimented by 20,000*g* for 4 hr. Its titre was reduced about 80 per cent by exposure to trypsin (0·2 per cent crystalline trypsin at 37° and *p*H 8 for 2 hr.), and also by heating (56° at *p*H 7·2 for 1 hr.). It was precipitated by 50 per cent saturated ammonium sulphate, and by dialysis against phosphate-citrate buffer *p*H 4·5. At *p*H 7·0, the antigen was adsorbed to *DEAE*-cellulose and was eluted by 0·2 *M* sodium chloride. It also adsorbed to calcium phosphate, being eluted by 0·2 *M* phosphate *p*H 6·7. These findings indicate that the serum-blocking antigen is a protein. Moreover, since the activity was eluted as a single peak from both *DEAE*-cellulose and calcium phosphate columns, it is likely to be a single substance rather than a mixture.

Rabbit-pox virus was also grown in *L* cells, primary rabbit kidney cultures, primary chick embryo cultures, and egg chorioallantoic membranes. The extracts were tested for serum-blocking activity, and all proved to be active. Vaccinia virus was grown in *ERK*1 cells, *L* cells, primary chick embryo cultures, and rabbit skin. Extracts of these tissues also possessed serum-blocking activity.

Having demonstrated a serum-blocking antigen, attempts were made to immunize rabbits. The extract from *ERK*1 cells infected with rabbit-pox virus was injected subcutaneously with adjuvant. The neutralizing antibody response of the animals was measured against vaccinia by Boulter's method[5]. A single injection produced a neutralizing antibody titre of about 1,000 after 4 weeks. Four injections at weekly intervals increased the titre to about 10,000, a level similar to that found in rabbits after recovery from infection with the living virus. The *ERK*1 cell extract was also fractionated on *DEAE*-cellulose, and the individual fractions used to immunize groups of mice. There was good correlation between the ability of fractions to elicit neutralizing antibody and their serum-blocking activity.

The neutralizing antibody formed in response to soluble antigen differed in some ways from that resulting from infection. The slope of the neutralization curve was less steep, with the result that a relatively high concentration of antibody was needed to produce almost complete neutralization of virus. Also, the neutralization titre against rabbit-pox virus was considerably less than that against vaccinia. In view of these differences, it would be unwise to attempt to predict the protective effect of immunization with soluble antigen. This problem is now being investigated.

It is concluded that the growth of rabbit-pox or vaccinia virus in a variety of tissues yields a soluble antigen which both combines with neutralizing antibody and elicits its formation when injected into rabbits or mice. It is hoped that the further study of this antigen will help to elucidate the mechanism of the infection of cells by pox viruses and its neutralization. The protective action of the antigen is not yet known; if effective, it might have practical application in the immunization of patients for whom a living vaccine is undesirable.

CYTOLOGY

Chromosome Elimination in Cecidomyidae

Adult members of the gall midges (Cecidomyidae, Diptera) are characterized by possessing a large number of chromosomes in their germ-line cells and a small number in their somatic cells[1]. This difference is established during one or more of the early mitotic divisions when a large but species-specific number of chromosomes is eliminated from all the nuclei destined to form the soma. Elimination is caused by the failure of the majority of the pairs of chromatids to leave the equatorial plate at mitosis.

In *Mayetiola destructor* (Say) there are approximately forty chromosomes in the germ line cells and only eight in the somatic cells of both sexes. Elimination occurs in fourteen nuclei during the fifth mitotic division, when about 80 per cent of the chromosomes are eliminated. The remaining two nuclei, which prior to the fifth mitosis have migrated into the cytoplasm at the posterior end of the egg, do not divide at this time; cell walls surround them to form two pole cells. During subsequent divisions of the pole cells the full number of chromosomes is maintained, and the germ-line is formed.

It has been found that the two nuclei which do not divide during the fifth cleavage become associated at that time with particular granules which lie in the polar cytoplasm, at the extreme posterior end of the egg. Preliminary histochemical investigations indicate that these granules contain ribonucleic acid and are associated with many mitochondria.

In experiments designed to analyse the causes of chromosome elimination the extreme posterior ends of eggs containing the granulated polar cytoplasm were treated with ultra-violet irradiation before the two nuclei had migrated into this area. The remainder of each egg, containing all the nuclei, was shielded from the irradiation. In such eggs the two posterior nuclei took up their normal position near the polar granules and yet divided with chromosome elimination during the fifth mitosis. Eggs treated in this way later gave rise to embryos with the reduced number of chromosomes in all their cells. The presumptive germ cells, in spite of losing about 80 per cent of their chromosomes, still gave rise to the beginning of a germ line.

Similar effects were obtained by: (*a*) preventing the nuclei from migrating into the polar cytoplasm before elimination by constricting the eggs with fine nylon threads; (*b*) by centrifuging the eggs so that the nuclei were displaced and the polar granules were dispersed throughout the cytoplasm, where the granules lost their apparent function of preventing mitosis. In some eggs of both these experiments division with elimination occurred in all nuclei at the fifth mitosis. The constriction and centrifugation results confirm those of Geyer-Duszynska[2], working on another species.

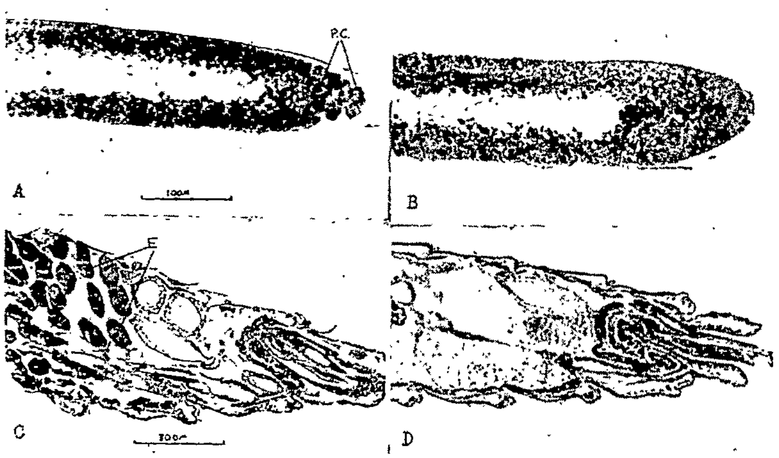

Fig. 1. *A*, Normal embryo at blastoderm stage. The large pole cells (*P.C.*) are at the posterior end; *B*, embryo at blastoderm stage in which the polar cytoplasm had previously been treated with ultra-violet irradiation. Note the absence of large pole cells; *C*, adult female with eggs (*E*); *D*, adult female developed from an embryo treated similarly to *B*. Note the absence of eggs

A few eggs, subjected to the irradiation treatment, were allowed to develop to maturity. So far, only females have emerged and been analysed. It was found that these were sterile and unable to lay eggs, although the secondary sexual characteristics were quite normal. The gonad consisted of a large mass of cytoplasm containing loosely scattered somatic nuclei and degenerating nuclei, apparently belonging to the germ-line. These nuclei were of small size, indicating clearly that they possessed a reduced number of chromosomes.

As a preliminary conclusion it appears that the polar granules prevent chromosome elimination. This might be due to an inhibition of the fifth mitosis in the presumptive germ-line nuclei, or to another mechanism, coinciding in time only with this inhibition. The absence of gametes in pupæ and hatched flies, which had developed from irradiated eggs, indicates that the lost chromosomes are required for gametogenesis.

This work was carried out during the tenure of a Christopher Welch scholarship. I wish to acknowledge advice and encouragement given by Dr. M. Fischberg.

Synaptinemal Complexes (Cores) in Primary Spermatocytes of Mouse under Elevated Temperature

WE have observed in the electron microscope and determined statistically the synaptinemal complexes or cores in primary spermatocytes of male mice, *C57 B1*, exposed to an environment of 34·5° C. and 60 per cent humidity. To avoid confusion from the presence of two generations of spermatocytes in the same section we have evaluated only stages I–VI of the spermatogenic cycle.

According to classical findings, elevated temperature reduces the pairing, of homologues[1]. Since our own earlier work[2] and that of others[3–5] has shown that the cores are the chromosomal organelles of pairing, we were interested to observe the effect of elevated temperature on these structures. While the typical complete core is a triplet structure this triplet owes its origin to the coming together of two 'single' structures, one from each homologue; the third structure arises at the line of union[2]. Would elevated temperature result in the presence of the diploid number of unpaired single cores, or would elevated temperature suppress formation of cores proper (triplets)? As shown in Tables 1 and 2 it appears that elevated temperature reduces the total number of cores formed and also interferes with pairing so that the percentage of single cores rises.

A breakdown of the heat-exposed series is given in Table 2.

The time-lag of recovery suggests that the critical biochemical event of core inhibition may occur in the spermatogonia at least 19 days before pairing; but the event can probably also be evoked much more abruptly[6]. Our point of view based on functional and morphological evidence is that the tripartite core, that is, the synaptinemal complex of Moses[3,4] or our core proper, unites two homologous chromosomes in synapsis. This view conforms with those of Fawcett[5], Moses[3,4] Kaufmann[7], and others. In contrast, Sotelo and Trujillo[8] suggest that the tripartite core proper represents a haploid chromosome because they find

Table 1

	Total cells	Total cores	Single cores	Single cores (per cent)	Total cores per cell
Control, 22° C.	60	367	7	2	6·15
Heat-treated, 34·5° C.	56	142	41	29	2·5

Table 2

Treatment	Total cells	Total cores	Single cores	Single cores (per cent)	Total cores per cell
After 28½ hr. heat	19	36	11	30	1·9
After 52½ hr. heat	10	21	8	38	2·1
After 76½ hr. heat, and 14 days recovery	19	60	5	8	3·2
Same, but 19 days recovery	8	25	10	40	3·1

tri-, penta-, and hepta-partite cores in the spermatids of certain insects. While their photographs leave no room for doubt, could not the existence of cores in these insects be a very interesting anomaly? Research on haploid and triploid forms and on strains carrying multiple inversions should settle this point.

The recent work of Charard[9] also agrees with the interpretation of Moses and our interpretation.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

GENETICS

Effect of Induced Awn Mutations on Yield in Wheat

FROM comparisons between sister lines of the same parental derivation segregating in awn character and from experiments using backcrosses, awns have been found to have a positive function as regards grain yield in varieties of bread wheat[1-3]. A spontaneous awned mutant isolated by Mackey[4] in the variety Scandia III outyielded the parent strain in trials carried out over a period of 5 years. Awns have been supposed to influence yield by increasing assimilation and transpiration and thereby the size of the grains. Fully awned mutants frequently occur when varieties belonging to the tipped 1 class of Watkins and Ellerton[5] (that is, awns 1–2 cm. in length and confined to the uppermost spikelets) are treated with both ionizing radiations and chemical mutagens[6]. Several such mutants were found by us in the M_2 progenies of the varieties *N.P.* 799 and *N.P.* 809 treated with phosphorus-32 and sulphur-35 (both 5 µc. per seed), X-rays (16,000 and 22,000 r.) and different dosages of fast and thermal neutrons. Both these varieties have the dominant epistatic gene *B*1 on chromosome 5*A* (nomenclature of Sears[7]) and the established awn mutations behaved as monogenic changes in genetic studies. The mutants had the somatic chromosome number 42 and no prominent change could be detected in their karyotypes.

Twenty-five awned mutants of *N.P.* 799 and six such mutants of *N.P.* 809 were grown in replicated rod-row trials during 1958. All the awned mutants of *N.P.* 799 yielded more than the parent strain, while in *N.P.* 809 some yielded better and some lower. In both the varieties, the mutants found to be most promising in the first trial maintained their superiority in trials conducted during subsequent years. The yield of these awned mutants is indicated in relation to that of the parents in Tables 1*a* and *b*.

Table 1. RELATIVE GRAIN YIELD OF AWNED MUTANTS

(*a*) *N.P.* 799

Trial conducted at:	Awned mutant	Yield (percentage of control)	
		1958–59	1959–60
New Delhi	799–25	120·11*	109·52*
	799–6	110·00*	103·17
Pusa (Bihar)	799–25	110·85*	104·49
	799–6	102·21	104·24

(*b*) *N.P.* 809

Trial conducted at:	Awned mutant	Yield (percentage of control)		
		1957–58	1958–59	1959–60
New Delhi	809–1	126·14*	111·12*	102·14
	809–6	106·43*	106·06*	—
	809–9	104·12	—	—
Simla (Himachal Pradesh)	809–6	—	110·68*	—
	809–9	—	106·10	—
Karnal (Panjab)	809–6	—	—	100·86

* Significantly higher.

The awned mutants of *N.P.* 799 and *N.P.* 809, the performance of which in yield trials is given in Tables 1*a* and *b*, resembled the parents in all other characteristics like maturity period, shape and quality of grain and rust resistance. Thus, the increased yielding ability of some of them could be due to the addition of awns. Vervelde[2] has shown that in warm and dry areas awns play a particularly important part in grain production.

In the plains of India, awned wheats are liked by the farmer since they are damaged less by birds and hence the fully awned mutants of *N.P.* 799 and *N.P.* 809 have a double advantage, that is, they help to satisfy the needs of the farmer and to enhance the yield of the strain. *N.P.* 799–25, an awned mutant which has performed well in the yield trials conducted until now, has been named *N.P.* 836, and it will be tested in larger trials during the coming years.

Of late, there has been much scepticism concerning the possibility of adding through mutation breeding a desirable trait alone to an established variety without simultaneously bringing about some undesirable changes. The agronomic qualities of the fully awned mutants reported in this communication would suggest that in polyploids like bread wheat, which readily withstand whole and part-chromosome deletions, mutation breeding may have considerable scope, particularly if the deletion of a dominant epistatic locus has a favourable effect.

We are indebted to Drs. B. P. Pal and A. B. Joshi for their advice and encouragement.

Transmission of Phosphorus-32 incorporated by Parents into Descendants of *Drosophila melanogaster*

THE quantity and distribution in various phosphorus fractions of phosphorus-32 incorporated into parents by feeding on media containing phosphorus-32 was followed in descendants of *Drosophila melanogaster* strain *Algeria*. The animals were bred at 25° C. in incubators on Belgowsky's culture medium[1] with some drops of a yeast suspension. Reciprocal crosses were made between animals grown on media containing isotopic and normal phosphorus. Repeated passages were carried out in order to eliminate the eventual contamination by phosphorus-32 of the culture media of the descended larvæ by the labelled parents. The fractionation of the phosphorus compounds was carried out according to the Schmit–Tannhauser method[2]. The amount of acid-labile phosphorus in the acid-soluble fraction was assayed by the method of Berenblum[3]. The lipoid-soluble fraction was extracted with a mixture of alcohol/ether (3 : 1). Deoxyribonucleic acid (DNA) was separated after acidification with trichloracetic acid. The protein phosphorus, represented as orthophosphate, was separated from the DNA remaining in the solution by direct phosphorus determination.

The distribution in seven different fractions of phosphorus originating from the culture medium and transmitted to the progeny is shown in Table 1.

Table 1. PHOSPHORUS FRACTIONS IN THE ONTOGENY OF *Drosophila melanogaster* IN γ P/100 LARVÆ

Stage of development	Four-day-old larvæ	Young pupæ	Imagos Female	Imagos Male
Weight per individual (mgm.)	1·82	1·34	1·30	0·92
Fractions:				
Alcohol-soluble	1040	970	1550	380
Acid-soluble	1720	2100	1070	375
Acid-labile	(472)	(1640)	(520)	(54)
Lipoid-soluble	27	23	75	67
DNA fraction	66	102	118	42
Ribonucleic acid fraction	2207	1198	848	532
Protein fraction	111	55	192	333
Total	5171	4448	3853	1729

It may be seen that the intensive morphogenetical processes are preceded by a marked increase in the acid-soluble fraction, mainly at the expense of the alcohol-soluble one. From the pupal stage onwards an increase of lipoid phosphorus was observed. The lowering of ribonucleic acid (RNA) content is significant and might be responsible for the decreasing rate of protein synthesis. A pronounced increase in protein phosphorus was observed in the imago.

Table 2. THE DISTRIBUTION OF PHOSPHORUS ORIGINATING FROM FEMALE AND MALE GAMETES IN THE PHOSPHORUS FRACTIONS OF THE OFFSPRING (γ P/1000 LARVÆ)

Fractions \ Direction of the crosses	Labelled female × normal male	Normal female × labelled male
Alcohol-soluble	4·8	traces
Acid-soluble	8·3	0·130
Acid-labile	(7·4)	(traces)
Lipoid-soluble	1·5	0·042
DNA fraction	1·3	0·054
RNA fraction	6·2	0·099
Protein fraction	3·3	0·150
Total	25·4	0·475

Table 3. THE DISTRIBUTION OF PHOSPHORUS DERIVED FROM THE MEDIUM AND FROM THE GAMETES IN THE F_1 LARVAE OF *Drosophila* (per cent)

Fractions \ Origin of phosphorus	Culture medium (per cent)	Labelled female gametes (per cent)	Labelled male gametes (per cent)
Alcohol soluble	20·2	18·8	—
Acid soluble	33·4	32·9	27·1
Acid labile	(9·1)	(29·4)	(?)
Lipoid soluble	0·7	5·9	8·7
DNA fraction	1·3	5·1	11·8
RNA fraction	42·2	24·5	20·8
Protein fraction	2·2	12·8	31·6
Total	100·0	100·0	100·0

The distribution of phosphorus-32 in the phosphorus fractions of the larvæ orginating from reciprocal crosses is given in Table 2.

It is clear that the quantity of phosphorus transmitted via the ovocyte is fifty times higher than that transmitted by the male gametes. This figure is probably even higher. We must take into consideration the possibility of polyspermy which is a widespread phenomenon in *Drosophila melanogaster*. In the case of a 25-fold polyspermy the transmission by ovocytes surpasses the male transmission 1,250 times. The possibility that the differences are to be attributed to a higher turnover rate of the ovocytes was eliminated by autoradiographic examinations.

The distribution of phosphorus-32 in the phosphorus fractions derived from the medium, from the gametes or the food is shown in Table 3.

It can be seen that the distribution of phosphorus-32 in various phosphorus fractions derived from food, from male or female gametes, is very different. It is obvious that an equal amount of labelled phosphorus is incorporated into the acid-soluble compounds of the alcohol-soluble fraction from both the food and the ovocytes. By contrast, only traces of a similar incorporation were found if the transmission took place via the male germ-cells. There was no remarkable difference in the acid-soluble fraction; however, more phosphorus was incorporated into the acid-labile fraction via the ovocytes than from the food. Relatively less phosphorus was recovered in DNA if incorporated directly from the food than after transmission via the gametes. The differences between the phosphorus content of the RNA and protein fractions might be explained by the different amounts of reserve substances and cytoplasm contained by the ovocytes.

Hexaploid *Dactylis*

A RECENT intensive survey of *Dactylis* has shown that tetraploids ($2n=28$) are widely distributed throughout the temperate parts of the world[1]. In Europe and Asia, regions where this genus is native, diploids are also found, and each of these has a comparatively limited range of distribution[2].

As a result of screening 175 populations derived from Europe, Western Asia, the Mediterranean and North Africa, wild hexaploids have been discovered in material from Cyrenaica, and these have been compared with wild hexaploids from Egypt, sent to us by Mr. R. Knight, of the Waite Agricultural Research Institute[3].

Taxonomically, these plants are indistinguishable from forms of *Dactylis glomerata* ssp. *hispanica* Domin. Both groups as grown at Aberystwyth have a stout root-stock with bulbous-based tillers, slender, stiff, tough leaves with markedly toothed margins, and slender wiry culms up to 60 cm. tall. The heads are usually compact, the range of forms which occur being similar in both groups. The florets are short, the lemmas having pubescent keels and the lobed apex characteristic of ssp. *hispanica*[4].

The first introduction formed part of a collection made by the Food and Agriculture Organization[5], and originated from the top of Tocra Pass, Cyrenaica, at an altitude of 350–400 m., with a yearly rainfall of about 300 mm. The soil was a stony red clay-loam (Accession No. *Bc* 4556 = F.A.O. 3076). The second population was collected at Rasel Hekma, at a low altitude in the Western Desert of Egypt, with a rainfall of 100 mm. (Accession No. *Bc* 4860).

Chromosome counts were made at meiosis on four plants from Tocra Pass[6]. Twelve of the Rasel Hekma plants were counted at Adelaide, and five of their progeny at Aberystwyth. All were hexaploid. Meiotic behaviour (Fig. 1) was studied by Keith Jones in 50 pollen mother cells of three Cyrenaica plants; the results are given in Table 1, showing some variation in pairing from plant to plant. In plant 13, bivalents predominated, quadrivalents and hexavalents were few and no odd number associations were seen. On the other hand, plant 4 is an interchange heterozygote, and partly as a consequence of this, multivalents were more frequently observed.

It seems probable that, in population plants not heterozygous for interchanges, bivalent pairing will be the general rule. Forty per cent of the cells in plant 13 formed bivalents only.

The size and fertility of the hexaploid pollen was assessed (Table 2). The fertility equals that found for diploid and tetraploid *Dactylis*[7]. The diameter of the pollen of the hexaploid was less than that generally found in the tetraploids, and we consider that this is probably associated with the extreme xeromorphic adaptation of these plants.

Table 2. Pollen Data

Ploidy	Material	Pollen: Diameter (arbitrary units) Mean	Pollen: Diameter (arbitrary units) Range	Pollen: Fertility (per cent)
2 ×	8 populations, including 7 sub-species	7·88	7·13–8·72	78
4 ×	6 populations, including 3 sub-species	9·09	8·67–9·60	82
6 ×	1 genotype, a twin seedling from a tetraploid	8·55	—	84
	Bc 4860, 1 population	8·40	8·00–9·10	88
	Bc 4556, 1 population	—	—	83

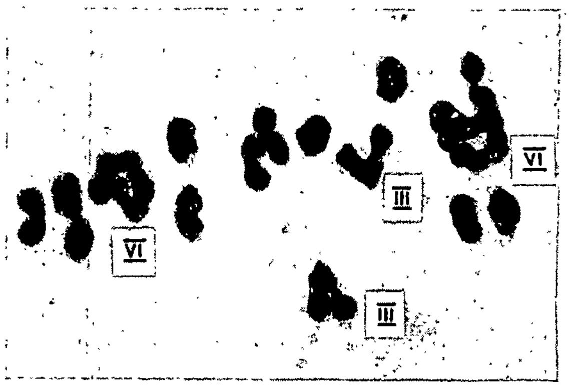

Fig. 1. *Bc*4556, No. 4 $2n = 42$. 2 VI, 2 III, 12 II

The discovery of hexaploid *Dactylis* in two localities in the same geographical area suggests that the type may have a much wider distribution in this region. Ecologically, these forms are adapted to dry conditions in areas of low average rainfall, and long periods of summer drought. These plants may, of course, grow in sites favoured by extra run-off moisture, as described by Boyko[8] for a *Dactylis* ecotype in Israel, which we found to be tetraploid (Accession No. *Bc* 4160). Even so, unequal distribution rather than actual amount of annual rainfall is probably the critical factor in relation to tolerance of drought.

The two most probable modes of origin of the hexaploid are by somatic doubling in a triploid hybrid, or following the occurrence of non-reduction in a tetraploid. Wild triploids have been reported from Israel in areas where diploids and tetraploids meet[9]. We suppose that the hexaploids arose by the doubling of such triploids, which, if they possessed favourable new combinations of genes, might be adapted to survive in the most extreme habitats, and be able to colonize such areas in the event of the chance restoration of fertility by chromosome doubling.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 1

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. R. Graham, Mr. J. W. H. Justice and Mr. J. K. Oxenham: "Progress Report on the Development of a Photo-electric Beam Index Colour Television Tube and System".

Society of Engineers (at the Engineering, Marine, Welding and Nuclear Energy Exhibition, Olympia, London), at 5.30 p.m.—Mr. R. H. Bound: "Jet Propulsion for Boats".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. Tom A. Margerison: "The Presentation of Science". (First of three Cantor Lectures on "The Presentation of Science and the Arts on Television".)

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Mr. E. G. Peppiatt: "Chemistry in the Service of a New Industry".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Capt. R. H. Grant, M.C., R.M. : "The Conquest of Annapurna II".

Monday, May 1—Tuesday, May 2

Electrical Association for Women (in London)—Thirty-sixth Annual Conference.

Tuesday, May 2

Institution of Electrical Engineers, Measurement and Electronics Sections (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. W. Pashley: "Structural Properties and Applications of Evaporated Metal Films"; Mr. J. R. Balmer: "Deposition of Evaporated Non-magnetic Films".

Wednesday, May 3

Zoological Society of London (in the Meeting Room, Zoological Gardens, Regent's Park, London, N.W.1), at 10 a.m.—Symposium on "Biological Acoustics".

British Institution of Radio Engineers, Computer and Radar Groups (at University College, Gower Street, London, W.C.1), at 3 p.m.—Symposium on "Computer Control of Air Traffic".

Institute of Physics and the Physical Society (in the Physics Department, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5 p.m.—Dr. Scott E. Forbush (Carnegie Institution of Washington): "The Equatorial Electro-Jet in Peru".

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. W. K. B., Marshall and Mr. V. I. Holmes: "Recent Developments in Arc Welding as Applied by the Petroleum Industry".

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Wednesday, May 3—Thursday, May 4

Institutions of Civil, Mechanical, and Electrical Engineers (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1)—Railway Modernization Conference.

Iron and Steel Institute and the Institute of Metals (at the Hoare Memorial Hall, Church House, Great Smith Street, London, S.W.1), at 2.30 p.m. on Wednesday and 10 a.m. on Thursday—Symposium on "Structural Processes in Creep".

Iron and Steel Institute (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1)—Annual General Meeting.

Thursday, May 4

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. D. M. S. Bagguley, Mr. R. A. Stradling and Mr. J. S. S. Whiting: "Cyclotron Resonance Over a Wide Temperature Range. 1: Germanium. 2: Silicon".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. W. L. Beament, Dr. H. E. Hinton, F.R.S., Dr. S. M. Manton, F.R.S., and Dr. John Smart: "On Aspects of the Classification of Insects".

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. G. P. Smedley: "Metals for Refrigeration and Other Low Temperature Installations".

University College, London (in the Chemistry Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. Hamilton: "Advances in Elementary Particle Physics".*

University of London (at the Senate House, University of London, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. Roger Y. Stanier (University of California): "Bacterial Photosynthesis".*

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. A. J. Birch, F.R.S.: "Some Pathways in Biosynthesis" (Simonsen Lecture).

Friday, May 5

Institution of the Rubber Industry and the Plastics Institute (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 9.30 a.m.—Conference on "Foamed Rubber and Plastics".

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Artificial Muscles" opened by Dr. A. B. Kinnear Wilson.

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 6 p.m.—Mr. R. Hafner: "The Helicopter—The First of the VTOL Aircraft".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Bart J. Bok (Canberra): "The Southern Milky Way".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer in the Department of Philosophy—The Registrar, The University, Leeds 2 (May 6).

Lecturer (preferably with an interest in physical biochemistry or the study of enzymes and their mechanisms) in Biochemistry—The Registrar, Manchester College of Science and Technology, Manchester 1 (May 6).

Research Assistant (chemist, preferably with two or three years research experience) for work on volatile inorganic compounds, in collaboration with Dr. L. H. Long—The Secretary, The University, Exeter (May 8).

Lecturer in Pharmacology—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (May 9).

Lecturer in the Department of Logic and Metaphysics—The Secretary, The University, Edinburgh (May 10).

Lecturer or Assistant Lecturer in the Department of Inorganic and Structural Chemistry—The Registrar, The University, Leeds 2 (May 12).

Senior Lecturer in Pharmacy in the Science Department, Jamaica College of Arts, Science and Technology, Kingston—Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (May 12).

Assistants (2) in Civil Engineering—The Secretary of University Court, The University, Glasgow (May 13).

Research Fellow in Pure Mathematics—The Registrar, University College, Singleton Park, Swansea (May 13).

Senior Scientific Officer/Scientific Officer Physicists (with a first- or second-class honours degree in physics, chemistry or metallurgy or equivalent) at the National Physical Laboratory, Teddington, Middlesex for (1) development of line gratings and detectors for X-rays in the wave-length region 1 Å. to 100 Å. and (2) application of diffraction gratings to the precise measurement of X-ray wavelengths—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.162/A (May 13).

Assistant in the Department of Moral Philosophy—The Secretary, The University, Edinburgh (May 15).

Lecturer in Agricultural Chemistry, with special reference to Animal Biochemistry and Nutrition—The Secretary, Wye College (University of London), near Ashford, Kent (May 15).

Lecturer or Assistant Lecturer (preferably with an interest in the fields of mycology and plant pathology) in the Department of Botany—The Assistant Registrar (Science), The University, Edgbaston, Birmingham 15 (May 15).

Lecturers and Assistants in Experimental Physics, Theoretical Physics and Electronics—The Secretary, The University, Aberdeen (May 15).

Lecturer in Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (May 20).

Lecturer (with a degree in veterinary science from an approved university, or equivalent, and at least three years postgraduate experience, including small animal practice) in Veterinary Medicine at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, May 20).

Organic Chemist (with a university degree or technical college diploma in organic chemistry, or equivalent qualifications, and preferably experience with biological systems) in the Division of Plant Industry, C.S.I.R.O., Canberra, A.C.T., Australia, to collaborate with a research group investigating the chemical nature and mechanism of action of growth regulators isolated from plants—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 130/469 (May 20).

Lecturer (preferably with a special interest in geomorphology) in Geography—The Registrar (Room 22, O.R.B.), The University, Reading (May 27).

Demonstrator (zoologist, botanist or geneticist) in Biology—The Registrar, The University of Adelaide, Adelaide, South Australia (May 29).

Reader in Chemical Metallurgy at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 29).

Senior Lecturers (2) (one with special interests in the field of mycology, and the other in anatomy, ferns or algae) in the Department of Botany, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 30).

Research Fellows (2) in the Department of Anthropology and Sociology, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, May 31).

Senior Lecturer or Lecturer (with postgraduate experience in research, coupled with a keen interest in teaching) in Physics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, May 31).

LECTURER IN PHILOSOPHY at the University of Melbourne, Australia —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 1).

READER (with appropriate academic qualifications and teaching experience) IN PHILOSOPHY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, June 9).

BIOCHEMIST (honours graduate), to assist with research on lipid metabolism in gastric mucosa—Dr. Billing, Department of Medicine, Royal Free Hospital, London, W.C.1.

BIOMETRICIAN (graduate with mathematical and biological interests, and preferably a knowledge of statistics) IN THE SECTION OF STATISTICS, for duties involving consultation and research on design and analysis of experiments—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks, quoting Ref. 61/12.

CHIEF TECHNICIAN (Grade 1) IN THE DEPARTMENT OF ZOOLOGY, to take charge of the technical staff and services of the Department, and to assist with planning in connexion with a proposed new building —The Assistant Bursar, The University, Reading.

INFORMATION OFFICER (university graduate with at least three years information experience, preferably in science and technology, and the ability to supervise professional staff)—The Director, Aslib, 3 Belgrave Square, London, S.W.1.

LECTURER (graduate in physics or chemical engineering) IN PHYSICS —The Principal, National College of Food Technology, St. George's Avenue, Weybridge, Surrey.

LECTURER IN BIOLOGY IN THE TRAINING DEPARTMENT, with particular interest in natural history—The Warden, University of London, Goldsmiths' College, New Cross, London, S.E.14.

LECTURER (with qualifications in applied chemistry or chemical engineering, and experience in industry, research or teaching) IN THE DEPARTMENT OF CHEMICAL TECHNOLOGY—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C.1.

LECTURER (with research experience) IN CHEMISTRY, to teach undergraduates and carry on fundamental research—Prof. J. K. N. Jones, Queen's University, Kingston, Ontario, Canada.

PHYSIOLOGIST or ZOOLOGIST (recent graduate) IN THE PHYSIOLOGY DEPARTMENT, to assist with research on the bio-assay of hormones in blood—The Secretary, National Institute for Research in Dairying, Shinfield, Berks, quoting Ref. 61/11.

RESEARCH ASSISTANTS (2) (with a Ph.D. or suitable taxonomic experience) IN PLANT TAXONOMY, to collaborate in compiling a flora of Turkey—Dr. P. H. Davis, University Department, Royal Botanic Gardens, Edinburgh 3.

SUPPORT FOR FUNDAMENTAL RESEARCH

IN reprinting, as part of its tenth anniversary celebrations, *Science: the Endless Frontier*, by Dr. Vannevar Bush, the National Science Foundation included an introduction by its director, Dr. A. T. Waterman, summarizing the extent to which, in the fifteen years since the report was published, its recommendations have been realized. Dr. Waterman recognizes that all the problems relating to the understanding and nature of basic research have not been solved, but he can point to a steady upward trend in Federal funds for basic research and to an increase in the number and diversity of Government sources providing such support. Some progress has also been recorded in research activities within the Government, and the establishment of the President's Science Advisory Committee is in line with the recommendation in the report that a Science Advisory Board should be created. Medical research was another major emphasis in Dr. Bush's report, especially basic research in this field, and here again there has been a rapid increase in available funds; and the organization established—the Division of Biological and Medical Sciences and the National Institutes of Health—meet and even go beyond that visualized in the report. In defence research, however, the situation is rather different from that visualized by Dr. Bush, but the substance of his principal recommendations is probably met by the arrangements with the universities continued by the Office of Scientific Research and Development, the generous support given to basic research by the three Armed Services, and by the number of leading scientists, both within the Department of Defense and in outside institutions, who are dealing with defence problems.

Something has also been done to improve the position with regard to international relations in science, notably by the appointment of scientific attachés, of a Science Adviser to the Secretary of State, and in such matters as visas, attendance at scientific conferences, etc. Notable progress has been made in implementing the recommendations in the chapter discussing the renewal of scientific talent, and, compared with a recommended programme of 29 million dollars by the fifth year, the National Science Foundation by 1960 had obligations for scientific personnel and education totalling more than 65 million dollars.

Recommendations relating to the dissemination of scientific information seem largely to have been fulfilled, and Dr. Waterman's introduction directs particular attention to the development of the National Science Foundation, the establishment of which was put forward as a principal means of implementing other major recommendations in the report. Its structure is substantially that recommended by Dr. Bush, and the Foundation has sought to observe the five basic principles enunciated by him. First, it seeks to ensure the continuity and stability that are needed in basic research; secondly, particular attention has been paid to the calibre of those serving either on its staff or as advisers or consultants; thirdly, it operates no laboratories of its own, but promotes research through grants or contracts; fourthly, it has kept to a minimum any conditions required of academic institutions; finally, it has not found its responsibilities to the President and Congress incompatible with independence and freedom of operation. While, however, Dr. Bush visualized the Foundation as the sole support in the Government of basic research, this has been far from the fact, and of about 200 million dollars for basic research in 1956, some 72 million dollars went through the Department of Defense, 45 million dollars through the Atomic Energy Commission, 26 million dollars through the National Institutes of Health, and the remainder was distributed through other Departments as well as the Foundation. In 1956, its fifth year, its funds totalled only 16 million dollars compared with 122·5 million dollars suggested by Dr. Bush, but in its ninth year, 1960, they had risen to 159·2 million dollars. Dr. Waterman considers that the organization provides the desirable flexibility as well as opportunity for expansion, but points out that there is still insufficient public appreciation of the importance of science and of education as distinct from technology.

This introduction by Dr. Waterman may be appropriately set beside the statement which introduces the Foundation's tenth annual report, covering the year ended June 30, 1960, which has now been published (see p. 494), and the chapter in the report, "Stimulating the National Research Effort", which reviews the Foundation's programmes for promoting basic research and education in the sciences in the broad context of the Federal Government's response to the challenge thrown down by the President's Science Advisory Committee in its report two years ago entitled *Strengthening American Science*. First, the progress of scientific research is considered, including the conduct of basic research, methods of support, facilities for research, participation by the United States in international programmes of research, notably in the International Geophysical Year and the continuing programmes of International Geophysical Co-operation and in the Antarctic, in which United States participation is developed and co-ordinated by the National Science Foundation, with recommendations from the National Academy of Sciences, and the communication of scientific information. Next, steps taken to assist the development of the individual scientists are outlined, such as the provision of fellowships, projects to train more science teachers and measures to improve the curriculum; and thirdly, those factors which determine the most favourable conditions for the growth of institutions for teaching and for research are considered.

On the first, the review emphasizes the extent to which the Federal Government now provides support for basic research; the man-power engaged in such research is to be found in some 450 universities and research institutions. It is interesting to note that, in discussing methods of support, the need for university co-operation is recognized. Like the Advisory Council for Scientific Policy in Britain, the National Science Foundation has come to recognize that desirable projects may cut across departmental boundaries and may even involve inter-university co-operation, and is now making grants of a broader type. As examples, one to the University of Pennsylvania is in support of research applying concepts of chemistry and physics to the biological problem of regulation of metabolism within the cell, while another will permit a concerted attack, at the Massachusetts Institute of Technology, on the problem of the production and nature of plasmas.

Here, and in regard to the provision of adequate facilities for research, the National Science Foundation and the Advisory Council for Scientific Policy appear to be working on similar lines; but the Foundation appears to be much more vigorous in its efforts to promote the communication of scientific information. Divergence is even more marked in regard to efforts to deal with the shortage of science teachers and the improvement of curricula, and it will be noted that in the Director's statement which precedes the review, Dr. Waterman suggests that for the future the main concern of the Federal Government in planning more effectively for science and technology should be in the field of education. Nevertheless, the Foundation's experience confirms that of the Advisory Council on Scientific Policy on the importance of sufficient Government support to research institutions and universities to ensure a proper balance of activities, and on the need to identify the critical areas of basic research and see that they are adequately supported; as well as to ensure that the possibilities of co-operative effort are not neglected, while, on the other hand, the weaknesses of massive, concerted efforts are also recognized and avoided.

Generally, the review suggests that Federal support of basic research and education in the sciences is sufficiently vital and flexible in the United States, though it is suggested that the situation calls for general aid to the universities on some such lines as those provided by the University Grants Committee in Britain. The Federal Government, however, is regarded as now better prepared for the discharge of its responsibilities in science, although stronger support for basic research is still required and the country's potential in science and technology is far from being realized. More effort, too, is needed in training scientists and engineers, and this is seen as a matter of widespread public recognition, understanding and appreciation of the importance of intellectual and scholarly activity and of the pursuit of excellence in all fields of intellectual endeavour.

Some of these points are emphasized even more strongly in Dr. Waterman's prefatory statement already mentioned. The National Science Foundation has a responsibility for the continuing study and analysis of the United States' scientific research and development potential, including research facilities, scientific man-power and education for science. Inquiries initiated seven years ago have now revealed trends that throw light on the present situation as well as assist long-range planning. It was these inquiries that led Dr. Waterman to the conclusion already quoted that the field of education should be the principal concern, and it is clear from his remarks that the United States is well ahead of Great Britain in action taken to remedy a situation that has become equally menacing to both countries. Admittedly, in the United States, little progress has been made in providing adequate salaries and career prospects for secondary school teachers of science, but in the United States standards have been tightened and critical thought devoted to the curricula and to improving the training of teachers and the content of courses. Beginnings of course have been made in Britain, as in the appointment by the University Grants Committee of a committee to study comparatively undergraduate teaching methods and practices; but concerted action is still needed and the situation requires urgent attention, just as it calls for tactful but firm handling.

Nevertheless, Dr. Waterman points out that these inquiries have shown that American institutions of higher learning are in critical need of assistance, especially in their graduate schools and other professional training centres. He comments on the effect of a widened gap between academic and industrial salaries, and on the fact that for several years fewer than 50 per cent on average of competent research workers in colleges and universities have received adequate support for the research they wished to pursue. A source of funds is needed that will enable a university to exercise initiative, judgment and competence in meeting its own needs, and it is this situation presumably that has led the Foundation to suggest, as already noted, a fresh look at the University Grants Committee system of Britain. Dr. Waterman does not wish to see the universities too dependent on the Federal Government for funds for research or training in research, and he stresses the way in which provision of uncommitted funds to universities, while from one point of view less effective than support of research projects, fosters the growth and independence of the institution and its contribution to research and education.

Support of basic research, Dr. Waterman suggests, should be regarded as a form of investment from which the returns in trained man-power are assured and research returns of definite value to the economy are statistically certain, and may more than repay the entire investment. Again, he recognizes the acute problem presented by the high cost of research equipment, more especially in certain critical fields of study, which are by no means always easy to identify, and which may require special scrutiny and decision on more than a scientific basis alone. Nevertheless, so far as the overall progress of science is concerned, he insists that the judgment of the active research worker should be the determining factor, and that the central planning and direction which are inevitable in development would be detrimental to scientific advance.

Generally, Dr. Waterman agrees that in spite of repeated emphasis on the importance of basic research, in the United States support has not been forthcoming on a scale sufficient to enable such research to hold its own in relation to the larger and seemingly more pressing problems of development. Although the position may be somewhat better in Great Britain, the experience of the National Science Foundation during the past decade affords no ground for complacency. The problems confronting the Foundation are similar in many ways to those facing the Advisory Council for Scientific Policy, and it is apparent that there are certain respects in which the Minister for Science might well take steps to see that these problems are tackled with more urgency and determination, and that the necessary co-ordination and financial support are forthcoming, even if it involves raising issues at Cabinet-level. Finally, the reader of this report can scarcely fail to note how much in it supports the argument advanced in the report, *Increasing the Effectiveness of Western Science*, for making the utmost possible use of possibilities of international co-operation in the attack on such major problems as space research, oceanography, polar research and the like.

THE PROCESSES OF DEVELOPMENT

The Biochemistry of Development

By Prof. Jean Brachet. (International Series of Monographs on Pure and Applied Biology. Division: Modern Trends in Physiological Sciences, Vol. 2.) Pp. xii+320. (London and New York: Pergamon Press, 1960.) 65*s*. net.

IN the years since the Second World War, biochemistry, which began with an interest in how living systems maintain themselves, has begun to find itself in a position to tackle the much more difficult question of how they come into being. Chemical embryology may be said to have become a separate branch of study with the publication of J. Needham's great three-volume treatise in 1931. Even that was mainly concerned with the maintenance metabolism of embryos, and it was only with the publication of the same author's *Biochemistry and Morphogenesis* in 1942, and J. Brachet's *Embryologie Chimique* in 1944, that the study of the chemical processes by which development itself takes place acquired a massive impetus. Brachet's classical book was revised and translated into English in 1950, and since then he has published another extensive survey of similar ground, in his *Biochemical Cytology* of 1957. In the present book, he returns to embryology. The work is, as he points out in the foreword, to be considered as a summary of the advances that have been made since the last edition of his *Chemical Embryology*. In general, it follows the plan of that book, with successive chapters on gametogenesis, fertilization, cleavage, two chapters on the chemical embryology of invertebrate and of vertebrate eggs, nucleo-cytoplasmic interactions during morphogenesis, and finally, the biochemistry of differentiation.

Prof. Brachet modestly discounts any claim to treat these subjects in a complete and exhaustive manner, emphasizing that he is concerned only with reviewing the recent advances. However, as we have learnt to expect from this author, the subjects which he chooses to treat include nearly all the topics which have attracted the attention of embryologists in recent years. Moreover, they are discussed on the basis of his well-known combination of extremely wide reading and considerable, original, and largely unpublished, observations by himself and his collaborators. The result is a book which has, on one hand, the merits of a very valuable work of reference, but which is also something much more, in that it presents a most stimulating general synthesis of the field as it is seen by one of the most active contributors to it. The recent period in embryology has been remarkable for the number and power of the new technical methods which have been made available for the investigation of developing systems. We have seen, in particular, the introduction of refined biochemical methods for studying the nucleic acids, and such technical advances as the use of tracers, electrophoresis, immunological methods, the electron microscope, nuclear transplantation, and so on. Brachet and workers in his laboratory have themselves used many of these methods, and he writes with real authority about them.

Perhaps Brachet's most characteristic contribution to our general theories of embryonic development is his emphasis on the importance of gradients of ribonucleic acid content in various regions of the egg and embryo. In this book also, the evidence on this subject is fully discussed, and a number of as yet unpublished observations are described. To me it seems that, although there is undoubtedly a great deal of importance in Brachet's concept of nucleic acid gradients, the conception does not do adequate justice to the undoubted existence of an enormously elaborate system of specific types of ribonucleic acid and protein. Indeed, biochemistry is probably not yet equipped to tackle this aspect of the matter. It is primarily the study of genetics which leads us to realize that any given cell probably contains hundreds, if not thousands, of different species of ribonucleic acid and protein. If any criticism is to be offered of Brachet's book, it is that one would like to have seen more genetics in it. Perhaps, however, it is unreasonable to ask for so much. A satisfactory synthesis between genetics and biochemical embryology is what we are all seeking, and one can scarcely demand of an author that he should provide something that no one has yet been able to formulate. We have enough to be grateful for in a work which deals with the whole biochemical side of development in a manner which is both thorough and also controversial enough to be stimulating.

C. H. WADDINGTON

POLAROGRAPHY

Advances in Polarography

Proceedings of the Second International Congress held at Cambridge, 1959. Edited by Ian S. Longmuir. Vol. 1: Pp. xv+1–407. Vol. 2: Pp. ix+408–803. Vol. 3: Pp. vii+804–1204. (London and New York: Pergamon Press, 1960.) £15 per set of three volumes.

THESE three volumes constitute the collected papers of the second International Congress on Polarography, held at Cambridge in 1959, in honour of the seventieth birthday of Prof. Jaroslav Heyrovsky, Nobel laureate. Many hundreds of investigators have published papers in this field of science since Heyrovsky's first research paper on this subject in 1924, and the passing years have brought not only a tremendous increase in our knowledge of the general theoretical principles governing polarography but also many important practical advances in the design and sensitivity of the related instrumentation. The applications of polarography have been outstandingly successful in the analytical and industrial fields, and have been extended and diversified to include investigatory work of the greatest importance to the biological, agricultural and medical sciences.

These proceedings of the Congress are published almost entirely in English, although the three volumes do contain a few papers where the text is in French or German, a circumstance which serves as a useful reminder to the more insular among us that science is, indeed, international, and that a modicum of linguistic ability has many advantages to the up-to-date scientist.

The volumes abound in theoretical excursions by international experts which must prove of the greatest value to the academic teacher or pure researcher. Ilkovic discusses his celebrated equation for the mean diffusion current in d.c. polarography, and detailed comments on the equations of Matsuda and Koutecky are also included in papers by Koutecky and other authors. H. Irving provides an authoritative paper on the stability of metal complexes and gives a detailed thermodynamic treatment of step-equilibria in solution: P. Delahay relates electrode process phenomena and polarographic theory: R. Brdicka presents an extensive theoretical treatment of kinetic currents and J. Heyrovsky gives a mathematical treatment of the principles of oscillographic polarography.

Recent advances in the instrumental techniques of polarography are dealt with in numerous papers by acknowledged experts. G. C. Barker and G. W. C. Milner describe the development for trace analyses of the highly sensitive square-wave polarograph and of the single-sweep oscillographic and a.c.-pulse instruments. H. M. Davies, J. Seaborn and H. I. Shalyosky present papers on the application of the differential cathode-ray instrument to 'subtractive' and 'comparative' polarography. Indeed, it is impossible in a review such as this to mention more than a small number of the eminent scientific authors who have made lucid and detailed contributions on newer instrumentation.

The three volumes abound in examples of practical analytical applications. The determination of trace impurities in semi-conductor materials; the estimation of dissolved oxygen; the reduction of pertechnetate ions; the polarography of molten nitrates, of chelate complexed ions, of ergothioneine and of various biologically important compounds are but a few of the experimental applications which receive detailed treatment.

Z. P. Zagorski presents a valuable paper on reference electrodes; the uses of solid micro-electrodes are discussed by several authors, and T. R. Mueller, C. L. Olson and R. N. Adams review the employment of boron carbide and carbon electrodes in voltametry.

The ramifications of the science of polarography within the overlapping fields of chemistry, biology and medicine are now so extensive that only a comprehensive collection of erudite papers of this type by many expert investigators could hope to present a realistic picture of present advances in practice and in theory. In these three volumes is an attempt at this herculean task, and the aim of the compiler has been largely achieved.

D. T. LEWIS

MEDICINE OF THE THORAX

Brompton Hospital Reports

Vol. 28, 1959. (A Collection of Papers by Members of the Staffs of the Hospitals for Diseases of the Chest—Brompton Hospital and the London Chest Hospital—and of the Institute of Diseases of the Chest.) Pp. xii+258. (London: Lloyd-Luke (Medical Books), Ltd., 1960.) 15*s.* net.

THE contents of this volume, which is as attractively produced as all its predecessors have been, maintain the high standard we have learned to expect from these reports. It is sad that this one should have to begin with a memorial notice to Sir Robert Arthur Young, who served both the staff and patients at the Brompton Hospital for so long. Joining the staff in 1905, he was one of the first physicians to realize the possibilities of thoracic surgery, and the long history of his life's work is admirably summed up here by the publication of the late Sir Gordon Gordon-Walker's address given at the memorial service. To read this address is to realize that Young was not only a great medical man but also a great human character.

The rest of the volume contains 16 articles on a variety of aspects of thoracic disease. Drs. L. H. Capel and J. Smart discuss in two papers aspects of effort intolerance; Drs. K. M. Citron, A. W. Frankland and J. D. Sinclair report on inhalation tests of bronchial hypersensitivity in pollen asthma, Drs. J. Pepys, R. Augustin and A. B. Paterson on common antigenic components of mycobacterial extracts and Dr. H. A. Fleming on differential lung function in atrial septal defect. Dr. Lynne Reid describes the connective tissue septa in the adult human lung and Dr. D. Ranger discusses the dangers of streptomycin with particular reference to its vestibular toxic effects. Dr. Paul Wood contributes two articles on pulmonary hypertension with reference to the vasoconstrictive factor and to reversed central shunt.

Surgery is represented by two articles by Sir Clement Price Thomas on the surgical treatment of pulmonary tuberculosis and on conservative and extensive resection for carcinoma of the lung, while J. B. Johnston and P. H. Jones discuss the treatment of carcinoma by lobectomy and sleeve resection of the main bronchus and W. K. Pallister describes a new endobronchial tube for the left lung. The value of the surgical contributions is greatly enhanced by the two articles by Sir Russell C. Brock, one of which is his Bradshaw Lecture on the present position of cardiac surgery (with its tribute to the work of Sir Charles Ballance and the part he played in the death of the superstition that the heart is untouchable), and the other is on direct operations for the correction of Fallot's tetralogy. Dr. J. G. Scadding contributes an opening article on the principles of definition in medicine, with special reference to chronic bronchitis and emphysema.

The bibliographies of all these articles are valuable, but would be more so if the titles of the papers quoted were given. The volume concludes with a list of papers published by members of the staff of the Brompton Hospital between August 1958 and July 1959 and with author and subject indexes to volumes 1–28. GEOFFREY LAPAGE

ELEMENTS OF PHYSICAL CHEMISTRY

Elements of Physical Chemistry

By Samuel Glasstone and Prof. David Lewis. Pp. v+758. (London: Macmillan and Co., Ltd., 1960.) 60*s*. net.

STUDENTS and teachers of physical chemistry will need no introduction to the *Elements of Physical Chemistry* by Glasstone and Lewis, the second edition of the book first produced by Glasstone in 1945. The major change in the new edition is a re-ordering of the chapters, so that after an initial outline of the properties of gases the reader is led through the realms of thermodynamics. This has the advantage of enabling such phenomena as vaporization of liquids and solids to be treated thermodynamically when first met, rather than phenomenologically as in the earlier edition. The molecular nature of matter is introduced in the billiard-ball approximation, in the chapter on the gaseous state via the kinetic theory, the more intimate details of the structure of atoms and molecules, and the direct evidence for their existence being left until a later stage. From this point onwards the book follows much the same well-established lines as the earlier edition. However, a new chapter on nuclear chemistry has been included. New material has been incorporated in all the chapters, to bring the book into line with contemporary developments.

The increased attention given to two of the basic theories of physical chemistry, namely wave mechanics and statistical mechanics, is welcome, although I feel that the section on the Schrödinger equation could well have been extended to indicate the way in which eigen values fall naturally out of the assumptions of the theory.

The book is written in such a way as to be readily understood by the student commencing the subject; moreover, the references given at the ends of the chapters should stimulate him to further reading of the subject. These references have been extended to include well-known review journals, as well as those to the *Journal of Chemical Education*, which were the sole source of additional information in the first edition.

To understand physical chemistry completely the student needs to acquire the facility to manipulate the results of experimental observation as well as the basic concepts. Development along these lines is encouraged by a new selection of problems at the end of each chapter, designed to set the reader thinking, and to develop his ability to interpret experimental results within the framework of physico-chemical theory.

The book is very well and attractively produced, and the figures have been well chosen to bring home to the reader the points in question. There is no doubt, in my mind, that the part played in the teaching of physical chemistry by the first edition will be more than adequately filled by the second.

A. MACCOLL

BRITISH FOOD ANALYSIS

The Composition of Foods

By Dr. R. A. McCance and Dr. E. M. Widdowson: Privy Council. Medical Research Council Special Report Series, No. 297. (London: H. M. Stationery Office.) 1960. (Third revised edition of Special Report No. 235.) Pp. viii+252. 30*s*. net.

THIS book of tables, giving the composition of a comprehensive selection of foods commonly eaten in Britain, is the third edition of the Medical Research Council Special Report Series No. 235, originally published in 1939. In 1942 the first edition was revised, the revisions including a change in the method of calculating the calorie value of carbohydrate, and the addition of 'National' 85 per cent flour and bread to the foods analysed. The second edition, published in 1946, included some other foods introduced into the nation's diet as a result of the Second World War. Both editions are well known to nutrition workers. The tables were the result of analytical work carried out under the direction of Prof. McCance since 1925. They showed the important organic and mineral constituents, with the exception of vitamins, of most of the foods in common use in Great Britain. Foods were analysed not only in the raw state but also as prepared for the table. The composition of many cooked dishes was given.

The basis of the third and latest edition remains the same. However, some foods no longer generally consumed have been omitted, and some of the many new proprietary foods which have appeared on the market since the War have been added. More than 100 new foods, including cereal preparations, soft drinks, sweets and alcoholic beverages, figure in this edition. Changes in the composition of various proprietary foods have made it necessary to revise values previously given.

Important and useful additions are two new tables showing the vitamin and amino-acid content of foods. The vitamin values are derived from assays made by other workers, while the amino-acid figures are a combination of the authors' own results and those of other workers.

In its revised form this well-known work will no doubt continue to serve nutrition workers and dietitians, retaining an honoured place among various other food composition compilations, national and international. The bulk of the tables is based on analyses of food samples carried out by the authors themselves, the results being given, for the main constituents, to the first decimal place. While such figures are, of course, accurate with respect to the samples analysed, they are not necessarily fully representative of the foods in question. Users of the tables should not forget that the composition of fresh foods varies widely even when variety and growing and harvesting conditions are uniform. Change in water content, for example, will obviously alter the whole composition of the food. All food composition tables, however carefully prepared, can in effect serve only as a guide in calculating the values of foods and meals. Joyce Doughty

FREE RADICAL TRAPPING

Formation and Trapping of Free Radicals

Edited by Arnold M. Bass and H. P. Broida. Pp. xvi+522. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 16 dollars.

ATOMS and free radicals, which normally react rapidly with surrounding molecules, can be 'trapped' in inert solids; if, for example, solutions in organic glasses are photolysed or products from a gas discharge are condensed at low temperatures. Free radicals have long been postulated as reaction intermediates, but only recently have many attempts been made to produce directly detectable concentrations of them in solids. That development has been rapid is shown by the size of this book. In 1954, seven laboratories independently published preliminary reports, their interest being mainly in determination of structures of radicals; in 1956, because of the slight possibility of production of sufficient concentrations of free radicals for use as rocket fuels, an intensive research programme was started at the National Bureau of Standards in Washington (under the direction of Dr. H. P. Broida).

Now that this burst of activity is over, research will proceed more slowly; this book will provide the background for the necessary period of consolidation. It begins with an excellent historical chapter by F. O. Rice, and there follow several chapters on methods of preparation and detection of trapped radicals. This approach, instead of arrangement by substances studied, is not easy to justify in the present state of knowledge and leads to considerable inconvenience—for example, data on trapped nitrogen atoms are scattered through eight of the sixteen chapters. However, it prevents the book from being a collection of research papers, and forces both authors and readers to reconsider the experimental problems of the field; indeed a certain amount of data relevant to the feasibility of trapping radicals appears here for the first time (Chapter 4).

A wide range of related fields and possible applications of free-radical trapping are dealt with in the later chapters. Some of these ("Rocket Propulsion") are highly speculative, others ("Radicals in Biological Processes") contain a great deal of background information and relatively few results; a shortening of the book, if accompanied by a reduction in the price, would certainly have been a great advantage. However, the editors' claim that this is a truly interdisciplinary field must be accepted, and among the new research workers for whose reference this book is written the spectroscopist will be glad to find a chapter on X-ray studies, and the biologist an elementary explanation of the application of electron-spin resonance, all in one volume.

B. Brocklehurst

A FRENCH LEXICON OF PLANT FORMATIONS

Les Formations Végétales et Paysages Ruraux

Lexique et Guide Bibliographique. Par G. Plaisance. (Publié avec l'aide du C.N.R.S.). Pp. 418. (Paris: Gauthier-Villars, 1959.) 3,000 francs.

LANDSCAPE, vegetation types and plant formations, as caused by factors of climate and soil and modified by man to suit his varied needs of food, pasturage and building, are basic factors in the evolution of languages and the history of civilization. Their ancient popular terminology has so often been the basis of place names and family names, and as such is studied by linguists, historians and geographers. In recent times they have become the special field of the botanical sciences of ecology, plant geography and phytosociology, which have introduced a disconcerting multitude of new words and phrases for the purposes of definition and classification.

To gather together the words and terms of several principal languages and continents for landscape, vegetation types and plant formations, from those of ancient dialects to the jargon of contemporary ecologists, has been the task of the author of this remarkable and fascinating dictionary. In the main *Lexique* each word, after definition, is given synonyms, examples of derivatives and main bibliographical references. After this there are special indexes of place names and family names derived from such words (for example, Fresnay (*frênaie*); Lafayette (*hêtraie*)); a trilingual, columnar lexicon for French, German and English terms; independent English and German indexes; another index, of botanical names; a vocabulary of technical terms used in ecology, plant geography and phytosociology; and, finally, a very extensive bibliography. The work is illustrated with small photographs and a number of maps. The maps of France showing the distribution, for example, of the many different dialect words for *hêtraie*, beech-wood, originating in fagetum, or of the great variety of words for expressing *défrichement*, are of absorbing interest.

Naturally, the work is strongest on the French side, and students of other nationalities will soon find defects and omissions, or will criticize the arrangement. I looked in vain, for example, for English 'down' and 'dune', and not enough attention has been given to recent Spanish publications and to Spanish words: for example, *pasto*, *pastizal*, *prado* and *pradera*, which appear in so many papers of keen, contemporary, Spanish agronomists should have been distinguished.

Nevertheless, every English ecologist and forester—one is tempted to say, every educated person—should examine this book, if only for repeated casual enjoyment and instruction.

N. Y. Sandwith

Spot Tests in Organic Analysis

By Prof. Fritz Feigl. Sixth, enlarged and revised English edition. Translated by Prof. Ralph E. Oesper. Pp. xx+675. (Amsterdam: Elsevier Publishing Company; London: D. Van Nostrand Company, Ltd., 1960.) 65*s*.

THIS book is a revised and extended edition of Prof. Feigl's celebrated work on the application of the spot-test identification techniques to organic compounds of many different types. Translated by Prof. R. E. Oesper, of the University of Cincinnati, Ohio, the text of this sixth edition is lucidly presented in a most readable manner, with large legible print on good paper.

The individual items in the sections dealing with tests for functional groups, tests for individual groups, practical applications, etc. have been almost doubled in number when compared with the fifth edition. Extensive detail is given in addition relating to the identification of polymeric materials, synthetic rubbers and fibres, vitamins, antibiotics, and various pharmaceutical preparations. Each chapter carries an extensive bibliography of references, and the volume ends with a tabular summary of the limits of identification attained with macro-drop (0·05 ml.) investigations involving the application of specific spot-tests to solutions of those elements, groups and compounds which have been given detailed treatment in the text.

The working laboratory methods for spot-test analyses are illustrated by clear, diagrammatic representations of the apparatus employed, and the actual test procedures for individual cases are described with much attention to experimental detail.

This volume will be as welcome to students and to professional analytical chemists as its predecessors have been, and is yet another attempt to keep abreast of the ever-growing research, development and interest in this absorbing field.

D. T. LEWIS

Ciba Foundation Symposium on Hæmopoiesis

Cell Production and its Regulation. Edited by G. E. W. Wolstenholme and Maeve O'Connor. Pp. xii+490. (London: J. and A. Churchill, Ltd., 1960.) 60*s*. net.

IN recent years important advances in experimental hæmatology have been made, particularly by the use of radioisotopes and cell-transfusion techniques. These advances are amply reflected in the sixteen papers presented at the Ciba Foundation symposium on hæmopoiesis. The stimulating discussions which followed each paper are also recorded.

The dynamics of hæmopoiesis is a conspicuous feature of this book. Attention is focused on the problem of the primitive stem-cell, the production and fate of lymphocytes, and the inter-relationship of lymphoid and myeloid tissues. Factors which regulate the production and release of blood cells are also discussed. The subjects considered include: (1) granulocytopoiesis in human and animal bone marrows studied by radioisotopes; (2) hæmopoiesis following cell transfusions into irradiated animals; (3) the construction, from experimental data, of models illustrating the kinetics of erythrocyte production, lymphocyte formation in the thymus, and plasma cell production in lymph nodes; (4) humoral factors in hæmopoiesis, including erythropoietin, a leucocytosis-inducing factor and batyl alcohol; methods are described for the assay of erythropoietin, including the use of transfusion-induced polycythæmia to study erythropoiesis; and the mobilization of vitamin B_{12} reserves is described following acute blood loss; (5) observations on the patho-physiology of human leukæmic cells, certain findings contrasting with conventional views of the leukæmic process.

The Ciba Foundation is to be congratulated on its latest publication. The papers and their clinical implications will be of considerable interest to clinical and research hæmatologists. The book contains much that is topical in hæmatological research, including observations upon human material.

P. F. HARRIS

Unity and Diversity in Biochemistry

An Introduction to Chemical Biology. By Marcel Florkin. Translated from the French by T. Wood. (International Series of Monographs on Pure and Applied Biology. Division: Modern Trends in Physiological Sciences, Vol. 1.) Pp. xiii+397. (London and New York: Pergamon Press, 1960.) 70*s*. net.

THIS monograph is presented as a collection of essays in which Prof. Florkin first reviews "the biochemical facts common to living beings", and then discusses biochemical differences between species. The treatment of unity in metabolic processes (Parts 1–4) is concise, yet complete enough to be of value to the general reader who wants an introduction to the present state of biochemical knowledge. Part 1 is a lavishly illustrated catalogue of the more widely distributed constituents of plants and animals. This collection is perhaps too detailed for an introduction to chemical biology (the structures of thirty-one carotenoids are shown), and most readers would welcome more comments on the relationship between structure and biological function. Part 2 includes a thoughtful discussion of thermodynamic aspects of biochemistry and a classification of enzymic reactions. Chemists and biologists will probably find Parts 3 and 4 the most rewarding in this book. These describe many of the reaction sequences which provide materials and energy for growth and survival of plants and animals.

In restricting a discussion of biochemical diversity to fifty-seven pages (Part 5) the author has been able to illustrate his arguments with only a few of the possible examples; comparative aspects of oxygen transport are considered in great detail. There is a welcome attention to biochemical differences between tissues of a single organism. Biochemical aspects of taxonomy and evolution are discussed briefly. Part 6 deals with the interaction of plants and animals with each other and with their inorganic environment, and concludes with the suggestion that loss of phosphorus to the sea may make life on the continents "a mere episode between two eras of marine existence".

Not everyone will agree with the author's choice of examples and references, but no other book deals with this wide range of topics so concisely, and the reader without biochemical training should find this a useful introduction to chemical aspects of biology.

THE HÆMOGLOBIN PARTICLES

CHEMICAL AND GENETIC ASPECTS OF THEIR STRUCTURE*

By DRS. G. BRAUNITZER, N. HILSCHMANN, V. RUDLOFF, K. HILSE,
B. LIEBOLD and R. MÜLLER
Max-Planck-Institut für Biochemie, Munich

THIS article presents a summary of work on the primary structure of human hæmoglobin A which was begun five years ago in the Max-Planck-Institut für Biochemie; the results have been published during the past two years in various publications, and we wish to summarize and discuss them here.

The hæmoglobin particle is composed of four peptide chains, two identical α- and β-chains[1]. Human hæmoglobin consists of the Val-Leu-type (the α-chain[1–3]) and of the Val-His-Leu-type (the β-chain[1,4]). Our investigations were conducted on the main component of normal adult human hæmoglobin. In order to elucidate its chemical fine-structure we have split the globin particle with trypsin after denaturation with urea[5]; as first shown by Moore, Hirs and Stein[6] with ribonuclease, this enzyme is the simplest method of splitting a protein into a discrete number of definite breakdown products. For the separation of a peptide mixture we have developed a new procedure employing an anion exchange resin ('Dowex 1*X*2')[7,8] and pyridine acetate as a volatile ninhydrin-negative buffer. The essential principle of the method is that the separation depends only on the charge and also that peptides of very long chain-length can be eluted from the column. Since this method does not require desalting, it saves a considerable amount of labour (Fig. 1). The purification of the peptides is achieved by high-voltage electrophoresis and paper chromatography. By use of these procedures all the breakdown products of globin, which come from the α- as well as from the β-chain[9–13], could be separated, isolated and characterized quantitatively, by means of the automatic apparatus of Spackman, Moore and Stein (Beckman Instruments, Fullerton, Calif.). By these means the exact amino-acid composition of all tryptic breakdown products, with the exception of the three cysteine peptides, could be determined. The cysteine peptides could be separated and purified only after oxidation with performic acid. The amino-acid composition of these breakdown products will still have to be established more precisely, since destruction during oxidation is not ruled out. The knowledge of the exact amino-acid composition of these peptides is of primary importance for work on the amino-acid sequence still to be done, but not for the questions to be discussed here.

In extension of these investigations we have also developed a new, systematic procedure which makes possible the determination of the relative position of the tryptic peptides within the chain[14,15]. This is achieved almost systematically by splitting tryptic peptides with pepsin and by splitting those peptic peptides containing lysine and arginine with trypsin. A schematic presentation of the method is illustrated in Fig. 2. In this way identical peptides can be obtained which originate from the same section of the peptide chain, from which the sequence of the tryptic peptides can be concluded without difficulty.

In this manner the twenty-seven tryptic peptides of human hæmoglobin—thirteen from the α- and fourteen from the β-chain—could be assigned unambiguously to their positions within the peptide chains, and the partial formula of the α- and β-chains of the main component of normal adult human hæmoglobin could be established. In order to obtain a deeper insight into the primary structure of the hæmoglobin particle, the amino-acid sequence of the tryptic peptides was investigated. For this purpose conventional chemical (dinitrophenol method[16], Edman degradation[17,18], hydrazinolysis[19–21]) and enzymatic methods were employed. All the sequence studies were subjected to continuous control by quantitative analysis. For these controls a simplified amino-acid analyser (apparatus from Bender and Hobein, Munich)[22] was used. Up to the present, we have been able to fix the positions of about two-thirds of the amino-acid residues.

Homologous Architecture of the Chains

Comparison of the tryptic peptides of the α- and β-chain already shows that several breakdown

Fig. 3. The homologous structure of the α- and β-chains of the main compound of the normal adult human hæmoglobin. The homologous and identical sequences of the α- and β-chains of human adult hæmoglobin have been placed under one another. The sequence blanks resulting from such a comparison have been left free. The amino-acid residues the positions of which have been established are boxed in, thus $\boxed{\text{Ala}}$. Those residues the positions of which have not yet been fixed are represented in their sequence of elution from the amino-acid analyser, for example, Ala

products of both chains are identical or very similar; free lysine can be isolated from both, which is evidence of a lys-lys-sequence; moreover, the peptides Ala-His-Gly-Lys, Gly-His-Gly-Lys, Tyr-His, Tyr-Arg also show similarities. It became clear after determination of the position of the tryptic peptides within the chain and especially after establishing the amino-acid sequence within these peptides that the two chains are constructed in a homologous fashion[23]. They behave, with respect to each other, like proteins of different species.

In order to facilitate comparison, we have placed both chains together in Fig. 3. As can be seen, a large number of identical and homologous sequences occur in both chains. It is noteworthy that the basic amino-acids lysine and arginine occur at very similar positions in both chains: it is already apparent from sequence analysis that corresponding sections of the chain bear the same net charge. Both chains contain a basic centre, although the β-chain contains one additional basic residue:

(α) Lys-Gly-His-Gly-Lys-Lys (56–61)
(β) Lys-Val-Lys-Ala-His-Gly-Lys-Lys (61–66)

It is of further interest that the cysteine in both peptide chains—as one can tell from present investigations—is located in the last third of the chain.

The 'Blanks' in the Sequence

The individual homologous sequences of the α- and β-chain can only be made to match by omitting several amino-acids from an opposing position[23]. For example, the histidine in position 2 of the β-chain appears to have no partner in the α-chain. The homologous structure of the two chains can only be preserved by omission of this amino-acid: or, in other words, the α-chain has a 'blank' in the sequence in the equivalent position. The β-chain shows a similar behaviour in that it likewise possesses no partners for the amino-acids His-Ala (position 20–21) in the α-chain. There can be no doubt that the sequences (α) 56–61 Lys-Gly-His-Gly-Lys-Lys and (β) 61–66 Lys-Ala-His-Gly-Lys are homologous. It is, however, surprising that these sections in the chains are shifted five amino-acid residues apart. While the sequence of the preceding peptide in this section of the β-chain is already known, the equivalent peptide from the α-chain has not been determined analytically. It would be expected that a restriction for five amino-acid residues of the α-chain occurs in that part of the chain. As reported in earlier communications[12,13], and as is evident from Fig. 3, the constitution of the last third of both peptide chains is not yet known unequivocally. Although the exact number of amino-residues of the β-chain is not yet definite, because of uncertainties in the analysis of both cysteine peptides, it is already possible to say with certainty that the β-chain is larger than its homologous α-chain and contains approximately eight more amino-acid residues, whereas up to now only homologous chains with the same number of residues have been described.

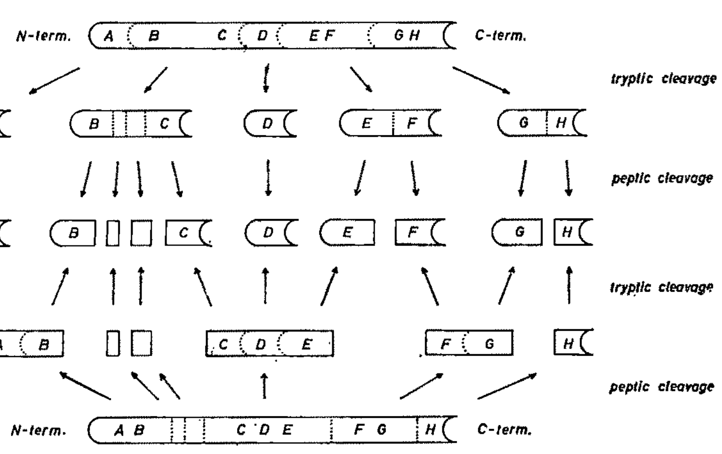

Fig. 2. Method for determining the position of the tryptic peptides within the chain

Theory

The structure of a protein reflects the structure of genetic material. A theory of protein structure is therefore equivalent to a theory of genetic substance. It must be assumed that originally a

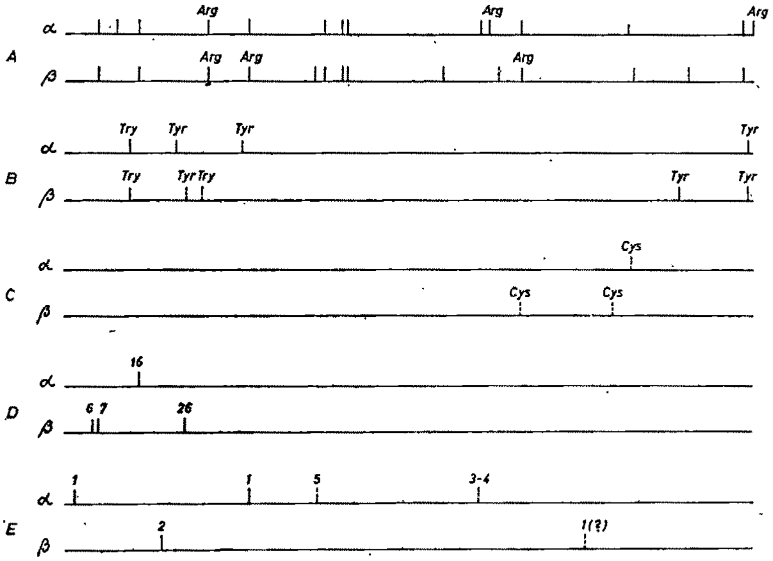

Fig. 4. Comparison of the peptide chains of the main component of normal adult human hæmoglobin. (*A*) Comparison of the position of lysine or arginine residues; (*B*) position of the amino-acids tyrosine and tryptophan; (*C*) most probable position of the cysteine residues; (*D*) position of amino-acids in which the specific genetically determined replacement of amino-acids occurs in pathological hæmoglobins (refs. 27–31); (*E*) position of blanks in the sequence; the broken lines mean that the exact position is not yet established; the numbers indicate the number of amino-acid residues missing in the chain and referred to as 'blanks'

simple hæmoglobin existed; it consisted of a single peptide chain which corresponded to an equivalent complementary piece of genetic material. During evolution and further differentiation, a duplication of the genetic material must have occurred, which, however, from that point developed and differentiated independently, until it corresponded to the double peptide chains found at the present time. These changes must have occurred a long time ago, since the differences between the chains are rather extensive. Besides these changes, the genetic material must have been subjected to a restriction; this is probably the simplest interpretation of the sequence blanks in the protein structure of hæmoglobin. In other words, the α- and β-chains behave like different species of peptide chains. Phylogenetically, however, the difference between the α- and β-chains is greater than the difference which has, for example, been found in the various kinds of insulin[25], where only an exchange of peptide chains of equal length has been established. In view of this finding, it seems to us that further essential insight into the structure of proteins has been achieved.

Sanger[25] was able to show—as indicated above—that proteins of various sorts differ by replacement of certain amino-acids. We believe that we have demonstrated experimentally, for the first time, a restriction at the molecular level. This finding can therefore only be explained if two complementary chains occur in hæmoglobin, whereby one in a certain sense serves as a standard for comparison and vice versa. The question of the linear structure of a molecule appears to us to be of the greatest importance for an understanding of evolution on a molecular basis. These results provide fresh stimulus for a comparison of proteins of various species, and also of the investigation of proteins with several peptide chains. It remains to be seen whether findings in other proteins will extend the results presented here.

A year ago, a three-dimensional Fourier analysis of horse hæmoglobin with a 5·5-Å. resolution was reported in *Nature*[26]. A resolution of 2·0 Å. appears now to be possible. The partial formula of human hæmoglobin presented here already contains all the essential outlines of its primary structure. It is only necessary to complete about 110 sequences, which, however, offer no further methodological difficulties.

In order to give a more complete and clearer view of the position in this field of work, we have arranged several reference points in the structure of hæmoglobin peptide chains opposite to each other in Fig. 4.

Further details of these results will be presented in *Hoppe-Seyler's Zeitschrift für physiologische Chemie.*

We wish to thank Prof. A. Butenandt, director of this Institute, for his generous support of this work. These investigations have been aided for the past several months by a grant from the Deutsche Forschungsgemeinschaft. We also wish to thank Miss B. Schrank, K. Haselhorst, R. Pagel and Mr. O. Ilg for assistance.

POLLEN ANALYSIS IN UGANDA

By Dr. M. E. S. MORRISON

Makerere College, Kampala, Uganda

THE vegetations of the past thousands of years can be reconstructed accurately by isolating and identifying the pollens which are preserved with their diagnostic features intact in the anaerobic sediments of fen and lake. In Europe this work, known as pollen analysis, has established a succession of vegetation types which appeared since the retreat of the last ice sheet some 10,000 years ago, and active work delves into more remote eras. These vegetation types probably arose in response to the different climates which prevailed in the past; and although there are many factors which obscure a straight correlation between vegetation and climate it is entirely true to say that pollen analysis has provided the most accurate and consistent story of Europe's environmental past. The vast body of facts which has been gleaned may be appreciated very readily by browsing through Godwin's[1] recent book *The History of the British Flora*, which has the telling sub-title *A Factual Basis for Phytogeography.* All this has been accomplished by a few enthusiastic workers within the past thirty years. The question I now wish to consider is: Can pollen analysis give an equally informative record of the Quaternary history of East Africa?

This is the question which Hedberg[2] put into many minds when he indicated recently that pollen analysis might be successful on the lakes and fens of tropical East Africa. In Uganda it would certainly be very good to have new and independent evidence for the history of vegetation and climate in the Quaternary period, because it is certain that Uganda has suffered an over-emphasis of correlations based on climatic interpretations of important stratigraphic sites, such as those alongside the Kagera River. Wayland[3], who has travelled widely in Uganda, and was for many years the director of its Geological Survey, believes firmly that the Kageran stratigraphy supports an interpretation—perhaps not wholly—in terms of pluvial and inter-pluvial periods. Brooks[4] suggested that these might have been the tropical counterparts of the glacial and interglacial periods of the north temperate region. Wayland, however, stresses that the terms 'pluvial' and 'inter-pluvial' are unfortunate because in some minds they conjure up fantastic ideas of Noachian deluges separated by periods of extreme desiccation. Bishop[5] is an informed antagonist to the out-and-out climatic ideas, and it is instructive to compare his and Wayland's interpretation of the unquestionably important Kageran stratigraphy. Much of the difficulty and ambiguity in the evidence springs from the fact that beaches and terraces in East Africa cannot be straight away linked to climatic fluctuations, for changes in drainage and in lake-levels may have originated in tectonic movements, which have been extensive between the eastern and western rift valleys and around the Lake Victoria basin[6].

Part of the past year was spent in searching for suitable pollen-bearing deposits in Uganda, and, having had the good fortune to discover some excellent sites, I am sure that many of my colleagues will be interested in their whereabouts, and in the results from our first long pollen profile from this region.

Organic deposits, which have preserved pollen, are not common in Uganda because in the continuously warm climate the bacteria work very efficiently and all plant debris is rapidly mineralized. Thus, although there are vast swamps[7,8] of papyrus (*Cyperus papyrus*) and tall grass (*Miscanthidium violaceum*) all around the shores of the Lake and on the rivers, these are underlain usually by fine clays. These swamp clays, which are useless for pollen analysis, occur widely in the kingdom of Buganda, lying to the east and west of Kampala. The altitude of the region is about 4,000 ft.; the temperature ranges between 60° and 80° F.; the rainfall varies from 30 to more than 70 in. per annum, according to the locality; and the potential evaporation is a little more than 40 in. per annum. But at 6,000 ft. as near Kabale (Fig. 1) the temperature-range is 50–70° F., and the more sluggish bacterial industry allows peat to form and accumulate, and its depth is ultimately decided by drainage. The rainfall around Kabale may be about 40 in. a year and the annual potential evaporation about 30 in. In the Kashambya valley, near Kabale, Dr. Lind[7] found a maximum of a little more than 6 metres of peat, and in the Ishasha Valley—which is about the same altitude as the Kashambya—I have drilled through 14 metres in one place and reached the base, but through 18 metres in another place and not touched solid bottom. These, however, are possibly rapidly formed peats; but we find splendid compact peats and muds, which have formed probably slowly over many thousands of years, in the Rukiga Mountains, which are a short distance away, between Kabale and Kisoro.

Geologically speaking[9], the Rukiga Mountains consist of a 27-mile-wide belt of strike-ridges with intervening valleys—which are mature and very steep—descending often to a depth of 1,000 ft., and sometimes to 1,800 ft. This is the little Switzerland of Uganda, and it is much loved by all who know its hard-working, cheerful people, and its beautiful views of hilltops and island-studded lakes. As with most of Uganda, this countryside has been modified by changes of the Earth's crust, and here these movements have originated from the western rift valleys. But the lakes and fen-filled valleys, for the most part, owe their origin to drainage which has been impounded behind small volcanoes and lava flows. The now dormant and very lovely volcanoes, Muhavura, Mgahinga and Sabinio, are at the very south-west of the Rukiga Mountains, and they are part of the larger volcanic field known to geologists as the Bufumbira Bay. There are also small volcanic centres, such as Muko in the heart of the Rukiga Hills; the deposits around Muko are very interesting.

Muko is a tiny village from which a long, extremely narrow, and steep-walled valley runs into the north-west. This valley is neatly dammed by a cluster of small craters which rise to about 200 ft. behind the village. Drainage of the valley accumulated behind

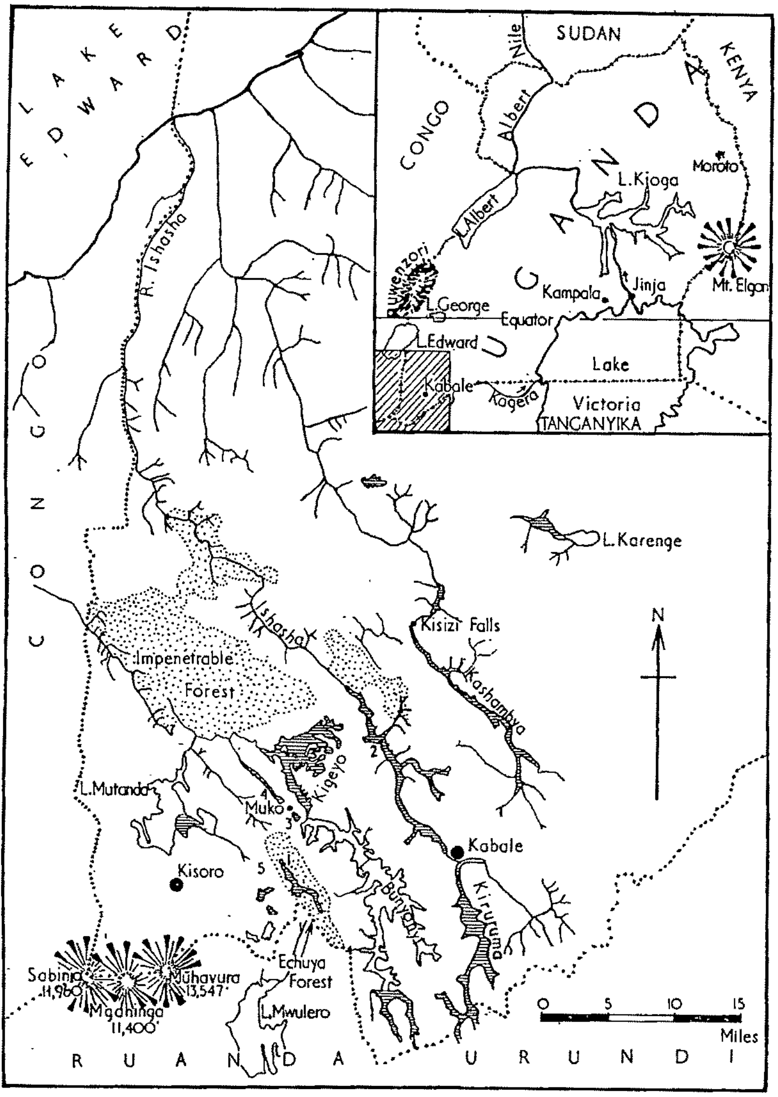

Fig. 1

this dam and a long lake formed, and this is now almost entirely filled in by lake muds and peats. In this valley, and just a short distance back from the volcanic bar, samples were collected through 20·5 metres of lake muds, and the base was not touched. The composition of the peat at that depth leads me to believe that there may be at least another 4–5 metres before the floor of the valley.

From Muko several sluggish lava streams made their way down the valley to the south-east so that finally they blocked the larger valley within which Lake Bunyonyi afterwards formed. Bunyonyi is an interesting lake with no indigenous fish, and this is remarkable because its overflow goes through Kigeyo fen and ultimately into Lake Mutanda, which has fish. But Bunyonyi waters are periodically deoxygenated. Now, part of the lava stream which halted at the north-west end of Lake Bunyonyi was diverted a little to one side by a rocky outcrop, and it impounded a smaller lake (site 3, Fig. 1) in a tributary valley. This lake has been completely infilled, and a drilling, believed to be near the centre of the deposit, gave 20 metres of lake muds, clay-muds and algal muds. The bottom, which was touched at this depth, was hard and presumably was a flooring of lava; the other dominant rock of the area is relatively soft Karagwe–Ankolean shale. Now, since the lake developed behind the lava flow and the lake muds rest on the lava, it is obvious that there are attractive opportunities here, and in the valley behind Muko (site 4), for correlating by pollen analysis and perhaps dating by radiocarbon the volcanic outbursts. Geologically, the lava flows should be relatively young because Lake Bunyonyi appears to have no high-level beaches, which means it has not yet had sufficient time to cut down the level of the outlet which flows over lava below Muko.

Other excellent deposits, and some of them similarly dammed behind lava flows, have been found on the Kisoro side of the Rukiga Mountains; one of these at a small village called Butongo (site 5) has been carefully sampled. Here a late stage of lake colonization has just occurred with a thick, floating mat of *Sphagnum* laced together with *Miscanthidium*. The drill penetrated very compact lake muds, lake clays and algal muds, this time to a depth of 20·5 metres. Near the base there was black ash in the mud, and volcanic pebbles.

The most elevated deposit we know of in the Rukiga Mountains is in Muchoya Valley (site 1); it is sometimes known as Elephant Valley. This valley is entirely enclosed by the Echuya forest reserve, which is of almost undiluted and dense bamboo (*Arundinaria alpina*). The valley has never been blocked by lava, but its drainage has been impeded by tilting, and for some time in the past there has been a long lake. The stratigraphy of the valley-filling was studied by drillings along a transect, and this proved a flat-bottomed valley, filled for the most part with lake muds. These are overlain by fen forest peat, and this in turn by a fen peat built up of tussocky sedges. The maximum depth of the deposit was 11 metres, and samples were collected at 2- and 5-cm. intervals, but with great difficulty in the lowest few metres because the muds were very firm and compact. It is from this valley that we now have the first long pollen profile from East Africa. I believe that this is an extremely important profile because of the position of this Muchoya deposit in the vegetational zones of the mountains. I worked on the theory, when choosing it, that a change of climate would have induced a movement of the altitudinally zoned vegetation of the Rukiga Mountains. Thus, there might be a record in the wind-borne pollen of a replacement of the bamboo by the succeeding zone of *Hagenia*, or by the underlying zone of Montane rain forest. Probably many readers are unfamiliar with these zones[10] of the East African mountains. There are three main belts: (1) Montane forest belt, 5,576–7,544 ft., 9,840–10,824 ft.; (2) Ericaceous belt, 8,504–11,152 ft., 11,480–13,448 ft.; (3) Alpine belt, 13,448 ft. upward. But the Rukiga Mountains with their peaks between 8,000 and 9,000 ft. are not high enough to harbour, to-day, the ericaceous and alpine belts, and indeed do not have even all the montane forest belt. This last-mentioned may have three zones, which reading from the base upward are: (1) montane rain forest zone; (2) bamboo zone; (3) *Hagenia* zone. The uppermost of these, the *Hagenia* zone, is absent to-day from the Rukiga range, and the bamboo consequently extends to the hilltops. The Impenetrable Forest, on slightly lower hills to the north-west of Muko, has only a few small areas of bamboo, and is dominated by rain-forest tree genera, including *Parinari* (Rosaceae), *Piptadenia* (Mimosaceae) and *Chrysophyllum* (Sapotaceae).

The entire pollen profile from Muchoya fen includes many genera of wind-borne pollen, and it would be confusing to reproduce it here where there is no space for an adequate introduction to the ecology of the plants involved. For simplicity, therefore, I have shown only two curves, *Hagenia* and *Stoebe*. *Hagenia*[11] is a rosaceous tree up to 50 ft. in height, with imparipinnate leaves and handsome panicles of flowers; the female reddish, the male white. *Stoebe*[12] belongs to the Compositae, and is a shrub up to 30 ft. in height, deceptively ericoid in appearance. According to Hedberg[12] it is "Co-dominant with *Philippia* spp. and *Erica* in forest or scrub on dry localities, sometimes scattered in grassland, from the (upper part of the) Montane forest belt, throughout the Ericaceous belt, and occasionally reaching into the lower part of the Alpine belt".

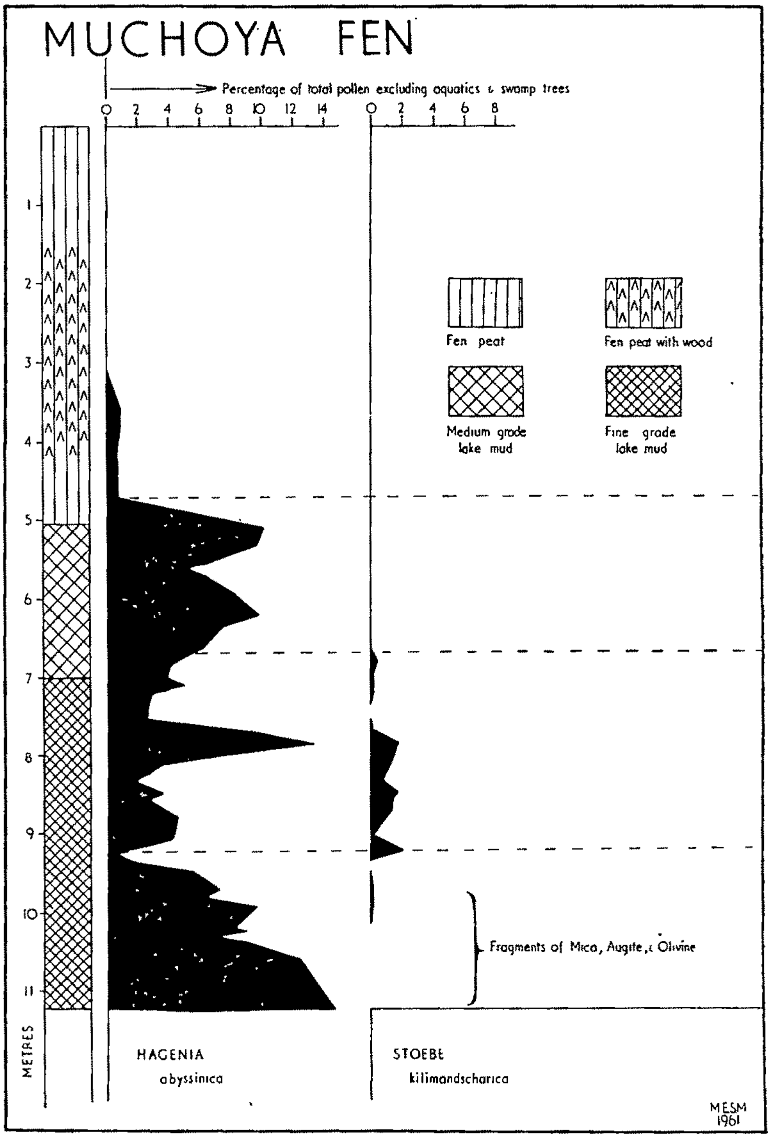

Fig. 2

Turning our attention now to the pollen profile (Fig. 2), we observe that, as the deposit began to accumulate, the surrounding hillsides were filled in with large amounts of *Hagenia*. Now this is very significant, because, as I have pointed out, *Hagenia* does not occur to-day on the Rukiga Mountains, except as occasional trees along the roadside and in clearings in the bamboo. From being initially high, the *Hagenia* percentages fall to a minimum close to 9 metres, and this could be regarded as completing the first zone of the profile. *Stoebe* was sparingly present in this first zone, but it becomes abruptly more prominent at the *Hagenia* minimum and its higher values persist to mark out, perhaps, a second zone in which, apart from a peculiar peak at 8 metres, *Hagenia* values are fairly low. At present we cannot explain these events because we know too little of the ecology of the plants. It is possible that this second period was one of greater cold, because *Stoebe* is more common in the ericaceous belt than in the montane forest belt. I believe, too, it is worth noting that *Stoebe* is not to-day known from the Rukiga or Ruwenzori Mountains, but it is recorded from western Congo, from Mts. Moroto and Elgon in Uganda, and from mountains in Kenya.

As *Stoebe* dwindles, the *Hagenia* recovers and reaches higher and sustained values which may mark out the third zone of the profile. This zone ends with the abrupt decrease of *Hagenia*, and I assume it was replaced entirely by bamboo, which has persisted to the present. Bamboo may, of course, have been intermingled with the *Hagenia* in the first three zones, but we have no evidence of this; and, in fact, its presence will not necessarily be recorded in the pollen. It is a strange fact that the bamboo on the Rukiga Mountains has never been found in flower, and the Africans of the area have no knowledge of its flowering at any time in the past. I think they are likely to have observed such an event because the plants die after flowering. I have heard it said that in the Far East large tracts of bamboo forest flower at long time-intervals, and the flowering is regarded as a bad omen. The bamboo fruits are much desired by rats which invade the area and afterwards set about ravaging stores of grain, so that ultimately famine may result.

Within limits, bamboo can be inferred in the upper part of the Muchoya profile from other observations. The bamboo is always accompanied by some plants which may exist also in the Montane rain forest. Thus one finds *Afrocrania* (Cornaceae), *Dombeya* (Sterculiaceae), *Lachnopylis* (Loganiaceae), *Mimulopsis* (Acanthaceae) and *Ilex* (Aquifoliaceae)[11]. Where we find pollen of these plants, but not of rain forest genera such as *Parinari* (Rosaceae), *Piptadenia* (Mimosaceae) and *Chrysophyllum* (Sapotaceae), then we may tentatively infer the presence of bamboo forest, though perhaps some of the first-mentioned genera could occur also in *Hagenia* scrub. I must add that bamboo does flower in some parts of Africa, and in my type-collection there is pollen taken from plants on Mt. Elgon and from the Aberdares in Kenya. The pollen is very large, and this, with the distinct pore morphology, distinguishes it from many pollens of the wild grasses.

With only this pollen profile for evidence, and little knowledge of the ecology of *Hagenia*, *Stoebe* and *Arundinaria*, one tends to fall back on climatic change as a cause for the former dominance of *Hagenia* and its replacement by bamboo. But we must be careful not to leap to a climatic interpretation because we are unable to discuss other perhaps potent ecological factors. We should also learn a lesson from the evolution of thought about European pollen profiles. These, at first, were explained almost wholly in terms of climate, but the most recent discussion[13] seems to find little room for climate and brings forward prominently succession, competition, and human interference. Therefore, it is right that we should emphasize the possible importance of these other causes for the 'shape' of the Muchoya profile.

Human interference perhaps may be ignored, because it is believed that the movement of people into the upper, cool parts of the Rukiga Mountains has been recent. But a reasonable explanation, on the other hand, in terms of ecological succession, could be constructed. Consider that *Hagenia* might arise in the place of bamboo if this vanished because of fire, or as a natural consequence of its flowering. I raise the possibility of fire because of the fragments of mica, augite and olivine in the lower several metres. These fragments must have come from a volcanic eruption, and, of course, if much ash had fallen on the landscape then fires might indeed have swept the bamboo. Afterwards it might not have recovered, for, unless the fire had immediately followed a rare flowering, there would have been no bamboo fruits to have given a new generation. But it seems improbable that there was a fire, and there is no layer of ash in the stratigraphy; and indeed the fragments of rock I mention are very minute and few. Since at present these considerations do not lead us to anything promising, we are possibly justified in assuming that the replacement of *Hagenia* by pure bamboo was caused by a change of climate—perhaps an amelioration—some hundreds or thousands of years ago. Without radiocarbon assay there is no possibility of dating any part of the profile. Interpretation of the profile will be very much easier when we have further profiles from the Rukiga Mountains. I have now commenced work on the 20·5-metres deep profile from Butongo (site 5). This site is not now in the bamboo forest, but is in the cultivated zone only 600 ft. below the present lower limit of the bamboo.

I have said nothing of the deposits actually hidden beneath lakes such as Victoria and Bunyonyi. These deposits cannot be sampled with the Hiller drill which was used for the other places I have mentioned. A special device is necessary to obtain deep-water samples, and Lake Bunyonyi is about 130 ft. deep. We hope to use an ingenious device created by Dr. F. J. H. Mackereth[14] at the Freshwater Biological Association's Laboratories at Windermere, England. It is powered by compressed air and obtains cores 6 metres in length, and it can work down to a depth of 250 metres of water. Because the diameter of the core is 1½ in. it should be possible to study pollen, plankton and chemistry. This should prove especially interesting in Lake Bunyonyi which, as I said earlier, is periodically deoxygenated and is without indigenous fish.

I hope this short account has indicated the richness and fascination of the field open to the pollen analyst in Uganda. I wish to thank the many friends from whose foresight and co-operation I have benefited. I am intensely grateful to Dr. Edna Lind, head of the Botany Department at Makerere College. Dr. Lind perceived the possibilities for pollen analysis in Uganda and arranged for me to be sponsored by the Nuffield Foundation and by Makerere College.

OBITUARIES

Prof. T. R. Elliott, C.B.E., F.R.S.

T. R. ELLIOTT was born in 1877, in County Durham, and went to Cambridge in 1896, where he took the Natural Sciences Tripos and later was elected to a number of already famous studentships. It was while he held these that Elliott carried out a series of researches in physiology which, in the words of Sir Henry Dale, "were of well-nigh incomparable brilliance and authority, for a worker so young in years and experience".

His interests lay in the effects of the autonomic nervous system, and his attention was caught early by the resemblance between these effects and those of adrenaline. These researches led him, far in advance of his time, to propose the concept of the chemical transmission of nerve impulses, thereby anticipating by nearly a quarter of a century the flood of productive work in this field. His election to the Royal Society in 1913 was a well-merited recognition of his brilliance.

In 1906, Elliott resumed his medical studies and, four short years later, he was appointed physician to University College Hospital, London. There he became closely associated with Thomas Lewis. This was the turning-point. The traditional structure of education in medicine had long been giving cause for concern, and the appointment of a Royal Commission under Lord Haldane to report on university education in London was the occasion for its searching analysis. Among the proposals made was that recommending the creation of whole-time professorial posts in clinical subjects. But the First World War came and delayed its implementation, and Elliott was in France by September 1914. Then followed four years of intensive work in which Elliott became the projection into the battlefield of the medical knowledge and skills which Walter Fletcher, of the old Medical Research Committee, was brilliantly mobilizing at home. As Elliott himself admitted, it was here that he discovered his power for combining science and administration.

The War ended; attention returned to the Haldane Report and Elliott became, inevitably, one of the first whole-time professors of medicine in London. It was expected that this would herald a spate of researches in the clinical field comparable to those that distinguished his early days in physiology. That this did not happen was largely Elliott's conscious decision. He recognized that, if clinical research was to draw level with the experimental biological sciences, then his generation had to sacrifice their personal advancement to developing and organizing the new scientific medicine; and the state of medical progress in Britain to-day is the present memorial to him and his fellows. The advancement of knowledge was his criterion. From the earliest days he was associated with the Medical Research Committee, and he was the only man who has ever served three full terms as a scientific member of its successor, the Medical Research Council. As an indication of the respect in which his judgment was held, it may be mentioned that, young as he was and not a member of the Committee, his advice was asked on the appointment of the first secretary, and it was he who suggested Walter Morley Fletcher.

But in the notices that have appeared since Elliott's death there has been one note common to all—respect for him as a man. Many men have been intelligent, upright and courageous, but in addition Elliott possessed an almost disconcerting ability to detect bias and an indifference to credit that, but for his tolerance, would have made him forbidding. It is no wonder that he remained the trusted counsellor of men with great responsibilities, or that, in need, his was the aid that was sought.

H. P. Himsworth

Rev. J. E. Hull

With the death of the Rev. J. E. Hull in October 1960 at the advanced age of ninety-seven we have lost the last of the Rev. O. Pickard-Cambridge's pupils in the study of spiders.

After leaving St. Bede's College, Hull took a degree in mathematics in the University of Durham before returning to St. Bede's as vice-principal in 1890. Later, his work as a clergyman in various Northumberland parishes confined his natural history work mainly to that county.

He shared with Dr. A. R. Jackson and W. Falconer the chief credit for making known the spider fauna of northern England. He described two British spiders new to science, and six of his proposed new genera have survived. He also did extensive work on mites and edited a northern quarterly journal, *The Vasculum*. His last paper was published when he was ninety-two.

W. S. Bristowe

Dr. M. F. E. Nicolai

Dr. M. F. Emilie Nicolai, algologist and biophysicist, director of the Hydrobiological Instituto at Hilversum, Holland, died suddenly at her home in Holland on March 13. There can be few people whose passing has brought sorrow to such a wide circle of devoted friends.

Dr. Nicolai was born at The Hague on June 27, 1900 where she received her early education. In 1918 she entered the University of Leyden as a student in biology and in the subsequent years she studied botany, zoology, mineralogy, geology, chemistry and physics. Her doctor's degree was awarded in 1929 on a thesis "On Changes in Permeability in the Root Cells of *Sinapis alba*". She remained associated with Leyden until 1942 first as assistant, and later head assistant, to Prof. J. M. Janse and then, from 1931 onwards, to Prof. L. G. M. Baas Becking. During this time her published work lay in the fields of physiology and ecology, though one of her papers (on chlorophyll multifilms, with Dr. C. Weurman) already indicated her interest in the application of physical principles and methods in biology. Her first serious work in the fields both of algology and in biophysics came during this period when, in 1937, she visited the Eidgenossische Technische Hochschule, Zurich, to work under Prof. Dr. A. Frey-Wyssling on the cell wall structure of *Chaetomorpha*. It was no mere coincidence that at this same time my own interests had turned toward the related genus *Cladophora*, causing us afterwards to work closely together for so many years. In 1942 Dr. Nicolai transferred to the Fibre Research Institute, Delft, under Dr. J. R. H. van Nouhouys, and in 1946 became head of the Biological Department. Though, so far as I know, she never worked with him, she was deeply impressed by Prof. G. van Iterson, jun., and it was largely through his influence that in 1947 she came to England first as my research assistant and then as lecturer at Leeds. This was the beginning of a fruitful collaboration on wall structure in the algae lasting almost ten years, opening up a new field and laying down a foundation of work for many years still to come. It was during this period that she made her name as an algologist. Our collaboration terminated when her loyalty to her country led her in 1957 to accept the position of director of the newly founded Hydrobiological Institute in Holland, though she frequently returned to Leeds.

Dr. Nicolai was a botanist of wide experience and a first-class investigator, and for this alone her death would be a serious loss. But she was much else beside. Warm-hearted and generous and with friendliness overflowing to all, 'Nick's' intuitive understanding of, and sympathy with, the problems of her associates never allowed her to speak ill of anyone. Though small in stature, she was always dignified. To many of us her calm unruffled manner was a source of constant strength, and we are all the better for having known her. Few women scientists can have been so well beloved as was 'Nick' by people in so many walks of life. Wherever she went, in Europe or farther afield, in shops or in the rooms of learned societies, she was soon surrounded by her friends.

R. D. Preston

NEWS and VIEWS

Royal Society : Foreign Members

The following have been elected foreign members of the Royal Society: Prof. Olaf Holtedahl, professor emeritus of geology in the University of Oslo and member of the Norwegian Academy of Sciences, Oslo, distinguished for his outstanding contributions to geology, particularly of Norway and the arctic regions; Prof. Solomon Lefschetz, Henry B. Fine professor emeritus of mathematics in Princeton University, Princeton, distinguished for his work in the fields of algebraic geometry and topology; Prof. Elmer Verner McCollum, professor emeritus of biochemistry in Johns Hopkins University, Baltimore, distinguished for his services to the science of nutrition; Academician Aleksandr Nikolaevich Nesmeyanov, president of the Academy of Sciences of the U.S.S.R., Moscow, distinguished for his contributions to organic chemistry, particularly on organo-metallic compounds.

Civil Engineering at University College, London : Prof. A. H. Chilver

Dr. A. H. Chilver, who has been appointed to the Chadwick chair of civil engineering in University College, London, in succession to Emeritus Prof. H. J. Collins, was born in 1926. He was educated at Southend-on-Sea High School for Boys and at the University of Bristol, graduating in 1947. He was awarded the Albert Fry Prize in 1947. After leaving Bristol, Dr. Chilver worked for a year with London Midland Region of British Railways on structural steelwork design. He then returned to the Civil Engineering Department, University of Bristol, in 1948, as a research student. He was appointed assistant lecturer in civil engineering in the University in 1950 and eventually lecturer in 1952. He left Bristol in October 1954 on his appointment as a University demonstrator in the Engineering Department, Cambridge. He was promoted to a University lectureship in 1956 and was elected into a fellowship at Corpus Christi College in January 1958. Dr. Chilver's main fields of research are structural stability and related problems; stability of thin-walled metal structures, stability of complete frames, buckling of shells; structural safety; loads on engineering structures and strength of structural materials. His publications consist of various papers on structural stability published in engineering journals, an elementary text-book on theory of structures written in collaboration with R. J. Ashby and another on strength of materials written in collaboration with J. Case.

Chair of Mechanics at Cambridge : Prof. D. C. Johnson

Prof. D. C. Johnson, professor of mechanical engineering in the University of Leeds, has been appointed to a chair of mechanics in the University of Cambridge. Prof. Johnson was born in 1915. He was educated at Mill Hill School and was a Minor Scholar at King's College, Cambridge, during 1934–37. He was placed in the first class in the Mechanical Sciences Tripos in 1937, gaining distinction in heat and heat engines. After leaving Cambridge, Johnson worked during 1937–47 for Rolls-Royce, Ltd., Derby. He returned to Cambridge in 1947 as a University demonstrator and was appointed a University lecturer in 1948. He was appointed secretary to the Faculty Board of Engineering in the University and elected into a fellowship at Trinity Hall in 1954, resigning in 1955 to take up the chair of mechanical engineering at Leeds University. Prof. Johnson's main field of research is vibrations, on which subject he has lectured widely and contributed several papers. His latest publication, "The Mechanics of Vibration", was written in collaboration with Prof. R. E. D. Bishop and published by the Cambridge University Press in 1960.

Nature Conservancy Appointments

The Nature Conservancy has appointed Prof. J. B. Cragg as director from June 1, 1961, of the Merlewood Research Station, Grange-over-Sands, and Dr. K. Mellanby as director from October 1, 1961, of the new Monks' Wood Experimental Station, to be built on a recently acquired site near Huntingdon.

Prof. J. B. Cragg

Prof. Cragg has had some twenty-five years experience of university work. In addition to his academic duties he has served on a range of major official committees and has visited Israel, West Africa and the Antarctic. He was appointed reader in zoology in the University of Durham (Durham Colleges) in 1946 and then professor in 1950, during which period he has written extensively on problems of conservation and ecology. Prof. Cragg is president of the British Ecological Society and chairman of the Agricultural Research Council's Pest Infestation Research Board. He has also played an active part in the affairs of the Institute of Biology as member of Council, editor and vice-president. The main research at Merlewood, which the Nature Conservancy set up in 1952, concerns the study of woodland ecology, with an emphasis on nutrient cycles. Moor House Field Station, on the Westmorland Pennines near Alston, Cumberland, will also be directed by Prof. Cragg.

Dr. K. Mellanby, C.B.E.

Dr. Mellanby is one of the few senior entomologists with experience in both medical and agricultural entomology. His main interest has been concerned with the reactions of insects to temperature and humidity, a subject on which he has written many papers. He has carried out much research work in Britain and other countries (mainly tropical countries). In 1955, he became head of the Department of Entomology of Rothamsted Experimental Station.

He is president of the Association for the Study of Animal Behaviour and vice-president of the Royal Entomological Society. The establishment of the Nature Conservancy's new Experimental Station at Monks' Wood (adjoining the National Nature Reserve) will provide Dr. Mellanby with a challenge and an opportunity for which his broad experience is especially relevant. When building is completed in 1962, the Station will house three teams studying the effects of toxic chemicals on wild life, ecological management of native woodlands and scientific problems of conservation. The Station will also form a base for field studies of the diploma course on conservation of University College, London, and for other university and related activities. The Station is already functioning in embryo in temporary premises, and it is hoped that it will be fully operative by 1963.

The James Craig Watson Medal : Prof. O. H. L. Heckmann

The James Craig Watson Medal of the U.S. National Academy of Sciences has been awarded to Prof. Otto Hermann Leopold Heckmann in recognition of his noteworthy contributions to astronomy. The Medal, established in 1874 by the bequest of Dr. Watson to recognize astronomical discoveries or work "worthy of special reward", was presented to Dr. Heckmann at the annual meeting of the Academy on April 24. As professor of astronomy in the University of Hamburg and director of the Hamburg Observatory at Bergedorf, West Germany's leading observatory, Dr. Heckmann is widely known for his work in astrometrics. Under the direction of his predecessor, R. Schorr, the Hamburg Observatory undertook about 1930 the enormous task of photographing and measuring the positions of the stars of the northern hemisphere. This work, known as the *AGK*2, was published in fifteen volumes. Dr. Heckmann initiated a repetition of it, enlisting the cooperation of a group of observatories in Canada, England, France, West Germany, East Germany, the U.S.S.R., and the U.S. Naval Observatory in Washington, to join in a concerted effort to derive, by new observations, the proper motions of 180,000 stars. Completion of the new catalogue, *AGK*3, is expected in about three years. Dr. Heckmann is internationally regarded as an expert in the field of relativity and cosmology. His work in this field includes not only contributions to the theory of cosmology but also critical assessments of the observational and experimental basis of cosmological theories.

The CIBA Fellowship Trust : Awards

The following were recently awarded CIBA fellowships: Mr. R. F. C. Claridge (University of Auckland and University of Cambridge), for post-doctoral work at the University of Cologne (radiochemistry); Dr. J. S. Littler (University of Oxford), for post-doctoral work at the Federal Technical Institute, Zurich (chemistry); Mr. H. Stern (University of Oxford), for post-doctoral study at the University of Brussels (theoretical physics); Mr. F. I. B. Williams (McGill University and University of Oxford), for post-doctoral work at the University of Liège (solid-state physics). Fellowships previously awarded to the following were renewed for a further year: Dr. V. P. Arya, at present working at the University of Stockholm (natural-products chemistry); Dr. W. D. Hamilton, at present working at the University of Uppsala (nuclear physics); Dr. R. Grinter, at present working at the Federal Technical Institute, Zurich (physical organic chemistry); Dr. B. L. Mordike, at present working at the University of Göttingen (physical metallurgy).

Scientific Development and the Budget

In his Budget speech on April 17, the Chancellor of the Exchequer, Mr. Selwyn Lloyd, expressed the view that productivity in Britain is being held down by shortages of skilled labour and that he is not satisfied that both sides of industry are invariably tackling this problem with sufficient energy. There are too few scientists and technologists. There are features in the tax system which make for inadequate rewards for initiative and enterprise. Some industries are insufficiently accustomed to competition and insufficiently aware of the need for technical improvement if they are to hold their own with their overseas competitors. Labour relations, standards of management and techniques of selling are sometimes below what is needed to-day, and certain industries are still, in his view, handicapped by restrictive practices which are completely out of date.

These comments were welcomed by Mr. H. Wilson, who wished to see them matched by action in scientific education and also measures to encourage scientific research in industry. He attributed the loss of young scientists and technologists to America to the poor prospects of promotion and inadequate salaries offered by many industries in Britain, and wished to see taxation on the middle ranges of scientists and executives reduced. The over-riding priority is to encourage science and technology. The total expenditure on scientific research, Mr. Wilson remarked, is £478 million a year, of which £370 million comes from public funds, while 52 per cent of the national expenditure on research and development goes on defence. Calling for a crash programme to train more scientists and engineers and a new policy for deploying them, Mr. Wilson urged even more a new and determined drive to apply science in industry. He suggested a wider use of the National Research Development Corporation and an expansion by 20 per cent of the 15,000 scientists at present employed on civil research and development.

The President of the Board of Trade, Mr. R. Maudling, agreed that we need much more research and development in British industry and also a rapidly expanding programme, as we now have, of scientific and technical education. Defence requirements, however, still limit the transfer of scientists and technologists from defence research to civil research. Mr. H. Nicholls thought that the Chancellor's surtax proposals would play some part in keeping in Britain the 2,000 scientists now leaving the country every year to work in competitor countries; the net loss, he pointed out, is about £1,000. Mr. D. Ginsberg, however, complained that the Budget did nothing to assist scientific research.

The Colonial Development Corporation

In a statement in the House of Commons on April 27, the Secretary of State for the Colonies, Mr. Iain Macleod, said that to ease the financial position of the Colonial Development Corporation, the Government had decided to release the Corporation from the obligation to meet the liability of accumulated unpaid interest on long-term Exchequer advances, now amounting to about £11 million, when they become due; the sum is to be placed in a special account in a way similar to that proposed by the Sinclair Committee, where interest will not be payable. The Corporation's debt of about £9 million, arising from projects abandoned by the Corporation, would also be placed in this account. Towards these two liabilities the Corporation would pay to the Exchequer 60 per cent of its net annual profits in excess of £250,000. The Government proposed to review these arrangements in three years time in the light of experience gained.

In future loan transactions, the period over which repayments to the Exchequer would be made would conform generally to that of the capital repayments which the Corporation would be receiving from third parties. For investments in shares, the Corporation would generally draw long-term advances for a 40-year period, and for this type of investment only the Corporation would not be required to service the Exchequer advances during the first seven years. Mr. Macleod said he was satisfied that these arrangements would be of real assistance to the Corporation and that they largely followed the recommendations of the Sinclair Committee. The Government had been unable to accept the recommendation that part of the advances should be converted to an equity share-holding in the Corporation, as this would have amounted to a subsidy over which there would not be full Government or Parliamentary control. In reply to questions, Mr. Macleod said that while the Corporation could bring to fruition projects it may have started in newly independent countries, its main effort should be made in starting new projects in the Colonies where the need was very great.

A Radio Telescope for the Department of Scientific and Industrial Research

A FULLY steerable radio telescope is to be built at a site near Crowthorne, Berkshire, by the Ministry of Works for the Radio Research Station of the Department of Scientific and Industrial Research. It is expected to be completed and in operation towards the end of 1963 at an estimated overall cost of £250,000, including buildings, equipment and site services. The instrument, which will have a parabolic aerial about 80 ft. in diameter, will have high accuracy and a faster tracking speed than the 250-ft. radio telescope at Jodrell Bank, an essential requirement for following Earth satellites and determining orbital data. It will be used to receive weak signals from distant space vehicles transmitting at ultra-high frequencies. In the field of radio astronomy, an application of the telescope will be a study of radio noise from the Sun, including sudden increases in radio emission which are related to disruption in short-wave communications. Also of interest is the radio noise from planets. The telescope will be valuable in extending investigations of the properties of the upper and lower atmospheres which are important in both terrestrial and space communications. This feature will assume even greater significance in the next few years, when satellites for communications, as well as for research purposes, are likely to come into use. In considering this project, the Council for Scientific and Industrial Research was advised by the following sub-committee: Sir Bernard Lovell (University of Manchester), Prof. Martin Ryle (University of Cambridge) and Dr. J. S. Hey (Royal Radar Establishment, Malvern).

Committee on Hydrological Research

IN reply to a question in the House of Commons on April 18 asking for the creation of an organization to conduct basic research into the conservation and utilization of water supplies in Britain, Mr. D. Freeth, the Parliamentary Secretary for Science, said that the Department of Scientific and Industrial Research has set up a Committee on Hydrological Research, under the chairmanship of Dr. B. K. Blount: "to survey and assess current research relevant to water conservation in the United Kingdom; to identify needs for further research; to allocate priorities and to determine where research should be done and to co-ordinate the work as necessary". The Committee has already held its first meeting and the Ministries of Agriculture and Local Government, as well as other bodies, are co-operating fully.

The membership of the Committee is as follows: Dr. B. K. Blount (*chairman*), Department of Scientific and Industrial Research; Dr. E. C. Childs (Agricultural Research Council); Dr. H. L. Penman (Agricultural Research Council); Mr. E. A. C. Johnson (Ministry of Agriculture, Fisheries and Food); Mr. J. K. Wilson (Department of Agriculture for Scotland); J. E. Munro (Department of Health for Scotland); Mr. R. F. Wood (Forestry Commission Research Station); Mr. C. H. Spens (Ministry of Housing and Local Government); Mr. A. C. Boulton (Surface Water Survey, Ministry of Housing and Local Government); Mr. P. J. Meede (Meteorological Office); Dr. E. B. Worthington (Nature Conservancy); Prof. M. V. Laurie (Department of Forestry, University of Oxford); Mr. P. O. Wolf (Department of Civil Engineering, Imperial College, University of London); Mr. N. A. F. Pountree (Institution of Water Engineers); Mr. M. Nixon (River Boards Association); Dr. R. C. Allen (Water Research Association); Dr. S. Buchan (Geological Survey and Museum); Mr. F. H. Allen (Hydraulics Research Station); Dr. B. A. Southgate (Water Pollution Research Laboratory).

Malaria Eradication Campaign

IN replying on an adjournment debate on the United Kingdom's contribution to the malaria eradication campaign on April 26, the Parliamentary Secretary to the Ministry of Health, Miss E. Pitt, said that the United Kingdom contributes already in four ways: through the regular budget of the World Health Organization; through the United Nations International Children's Emergency Fund; through the United Nations Technical Assistance Fund; and through the grants under the Colonial Development and Welfare Acts, the total expenditure under which for the purpose during the past twelve years was £760,000. In 1961 the contribution from the Malaria Eradication Special Account was about one-third of all that expended by the World Health Organization on malaria eradication, and amounted to 5·7 million dollars. The regular budget contributed 714,000 dollars, and the extended programme of technical assistance 639,000 dollars. The Special Malaria Fund of the Pan-American Health Organization contributed 3 million dollars and the United Nations International Children's Emergency Fund 8 million dollars, making a total of nearly 19 million dollars.

The Malaria Eradication Special Account was established in 1955 on the initiative of about 25 countries, but at the start the major Powers were opposed to the financing of such a scheme by soliciting voluntary contributions from Governments, and it was not until 1957 that the United States changed its policy and contributed 5 million dollars to the Account. The British Government maintained the view that such an eradication campaign should be financed through the regular budget of the World Health Organization (to which the United Kingdom contributes 7 per cent), and at the General Assembly of the Organization in New Delhi in February the United Kingdom supported a scheme which would put any shortage in voluntary contributions immediately on the regular budget. The administrative and operational costs of more than 600,000 dollars had already fallen on the regular budget in 1961; an additional 2 million dollars would fall on it for 1962, double this for 1963; and the whole 6 million dollars in 1964, an increase of more than 20 per cent in the 1962 budget of 23·6 million dollars. This would involve further contributions from the United Kingdom of 140,000 dollars in 1962, 280,000 dollars in 1963 and 420,000 dollars in 1964. Under the scheme adopted, which gives credits to the member countries carrying out malaria eradication campaigns and have low *per capita* incomes, a group of about 30 countries with relatively large *per capita* incomes will share the burden which in the past was borne by a few volunteers but mainly by the United States, which contributed about 90 per cent. Miss Pitt said that in the future the Director-General of the World Health Organization would be able to plan more effectively, since he could rely on the resources of his regular budget, and she also emphasized the substantial contribution from Britain on the technical side in research and training facilities.

Public Health Nursing

THE nursing profession throughout the world is faced with a severe shortage of recruits to its ranks. In the developed countries an increased burden is being placed on its shoulders by the growing complexity of medical services, treatment and equipment; the demand for nurses is rising at a time when the supply is falling off as a result of the availability elsewhere of better-paid jobs in easier working conditions. In the less-developed countries the demand for nurses is enormous; but the supply is restricted by unwillingness to allow women to become nurses, by the low status of nursing, and, above all, by the absence of the money to pay them. This crisis in the nursing profession has led to a re-appraisal of the functions of nurses and to various attempts to use auxiliary workers for the less-essential tasks of nursing, thus freeing nurses for the more-essential. A volume in the series of *Public Health Papers* by the World Health Organization contains a collection of papers by nursing and other experts from all parts of the world, who discuss the training and functions of public health nurses, the basic curriculum and the changes that the new situation is bringing about and should bring about in it, the importance of team work, the value of knowledge of administration, the role of the auxiliary worker, and the fresh approach now required of public health nurses (No. 4 : *Aspects of Public Health Nursing*. Pp. 185. 5 Swiss francs; 8*s*. 6*d*.; 1.75 dollars; by various authors. (Geneva: World Health Organization; London: H.M.S.O.) 1961). There are several contributions describing how countries—such as Brazil, France and the U.S.S.R.—have dealt with the problem of the auxiliary worker. A final paper discusses the difficulties met by international nurses working in other countries with strange cultures, different standards and attitudes.

Rural Research in C.S.I.R.O.

AMONG the many periodicals that nowadays come to our libraries, those of the Commonwealth Scientific and Industrial Research Organization of Australia have for long maintained a high value, and *Rural Research in C.S.I.R.O.* has for some years now kept agriculturalists well informed about the progress of agricultural research in Australia. The issue for December 1960 (No. 34, obtainable from the Agricultural Liaison Section of the Commonwealth Scientific and Industrial Research Organization, 314 Albert St., East Melbourne, C.2, Victoria) discusses the experimental work being carried out in Queensland on the rearing of cattle in a tropical environment, and the characteristics of the coats of the cattle in relation to this. Other articles deal with: research on the wool of sheep; sheep fluorosis; improved cobalt treatment of sheep; the use of the electron microscope in agricultural research (illustrated by striking photographs); soils and sulphur deficiency in soils; and new techniques which can extend the storage life of apples.

Bering Strait Dam

P. M. BORISOV has outlined a project, in the October (1959) issue of *Literaturnaya Gazeta*, of a 90 km. long dam across the Bering Strait equipped with powerful pumps pumping cold Arctic Ocean water into the Pacific Ocean at the rate of 500 km.^{3} in 24 hours. Such a project, according to Borisov, would increase the flow of warm Atlantic Ocean water into the Arctic Ocean and change the climate of the Arctic regions. This project is criticized by D. A. Drogaitzev (*Priroda*, 6, 35; 1960), who, on the basis of detailed calculations, argues that such a project would displace the locus of Atlantic Ocean cyclones to the region of the Barentz Sea. Such a displacement would certainly change the climate of Northern Europe and Western Siberia, but this change will produce colder winters and hotter summers and will lead to the displacement of the desert belt from the region of North Africa and Central Asia to the north of Europe. At the same time the northern Pacific region will also undergo a climatic deterioration.

The Manchester Museum

IN the annual report of the Manchester Museum for 1959–60, special mention is naturally made of three additions to the exhibition space. The special Japanese gallery to house the Lloyd collections has been completed, a coin room has been provided, and certain re-allocations with the University have made possible botanical offices and laboratories and the re-organization of the great herbarium. Two outstanding purchases were made during the year—two Celtic gold bracelets dug up in 1829 at Malpas in Cheshire and an Iron Age gold necklace found at Burnley in 1801. By the aid of various funds and a subscription list it was possible to purchase these three objects. A bequest of great importance was the Leslie Armstrong collection excavated from Pin Hole Cave, Derbyshire. It comprises about 14,500 bones, bone flakes, antlers and teeth. The report closes with an impressive list of publications by the staff.

The Birmingham Museum of Science and Industry

BIRMINGHAM CITY COUNCIL has approved the rebuilding of the Museum of Science and Industry.

Shortage of space for display and storage has prompted the Council to rebuild on the present site. Some of the very old buildings are structurally unsound, and would be most uneconomical to maintain in good repair. They will be demolished and replaced by a new building which will incorporate any suitable existing buildings. The scheme for rebuilding includes a new Locomotive Hall, an administrative block and an Engineering Hall. The scheme will be carried out in three phases over a period of several years. The total cost including professional fees will be in the region of £655,000.

Meteorites in the U.S.S.R.

IN the first quarter of the last century, certain curiously shaped hollows were discovered on the land surface of the Island of Sarema in Estonia, but it was only in 1927 that I. A. Reinwald produced the correct interpretation of their origin. As reported by E. L. Krynov (*Priroda*, 7, 55; 1960) these hollows represent meteorite craters. They were studied in great detail by Reinwald and after his death in 1945 by A. O. Aaloe, who carried out a systematic excavation of these craters and collected a large amount of fragments and dust belonging to iron meteorites. The disposition of the seven craters of the Kaalijarvi region suggests that, as in the case of the craters of Henbury in Australia, the Estonian craters are situated within an elliptical area of meteorite dispersion produced by a fall of meteorites which moved along a line stretching from south-south-west to north-north-east.

Reports of two meteorite falls in the U.S.S.R. have been forthcoming during the past year. According to M. A. Kashkai *et al.* (*Priroda*, 9, 109; 1960) an iron meteorite fell in Yardymly region, S.W. of Baku, Azerbaijan, at 8.5 a.m. November 24, 1959. This meteorite apparently broke into fragments before its fall as five distinct falls were registered. The collected fragments vary in weight from 360 gm. to 127 kgm. Calculations show that before fragmentation the meteorite was moving from the S.W. to the N.E. V. A. Yarmoluyk reports (*Priroda*, 11, 100; 1960) that a number of eyewitnesses observed a flight of a bolid accompanied by a flash and sound effect at 17h. 30m. local time on December 22, 1959, near the settlement Nurki, Dzhudzhur Range, fringing the Okhotsk Sea coast. It is presumed that these effects were caused by a meteorite fall, but no fragments of such have as yet been found in this region.

Artificial Melting of the Arctic Ice

A CONSIDERABLE handicap to navigation in the Arctic Ocean is presented by the delay of melting of ice in bays and river estuaries as compared with that in the open ocean. As described by I. S. Peschansky (*Priroda*, 7, 49; 1960), a most successful acceleration of the process of melting of ice has been achieved by dusting the surface of the ice with various dark-coloured materials along certain definite navigation lines. This allows a greater play of solar energy and the formation of 'radiation' channels a month and a half before the normal melting period of the ice.

Flora of the Rugby District

A GOOD example of the way an educational institution and the neighbouring community can work together is provided by a publication describing the flora of Rugby and its environs. It has been prepared by a former scholar, D. E. Allen, with records supplied by boys of the school and members of the town. To the original *Flora*, which was first published in 1957, has now been added a supplement providing details of recent discoveries (Rugby School Natural History Society. A First Supplement to *The Flora of the Rugby District*. Pp. 4. By D. E. Allen. (Rugby: George Over, Ltd.) 1*s*.).

The Royal Irish Academy

AT a meeting of the Royal Irish Academy in Dublin on March 16, Prof. John L. Synge, director of the School of Theoretical Physics in the Dublin Institute for Advanced Studies, was elected president. Prof. J. Doyle, Prof. J. J. Tierney, Prof. B. Ó. Cuív and Prof. F. E. Hackett were re-elected as secretary, secretary for polite literature and antiquities, secretary for Irish studies, and treasurer respectively. On the retirement of Dr. A. Farrington, who had been assistant secretary since 1928, Mr. Liam de Paor was elected executive secretary. The following were elected honorary members: in the Section of Science, Sir Harold Jeffreys, Cambridge, Edgar Lederer, Gif-sur-Yvette, and Lamoraal Ulbo de Sitter, Leyden; in the Section of Polite Literature and Antiquities, Roman Jakobson, Harvard, and Jerzy Kuryłowicz, Cracow. Mr. J. C. Beckett, Dr. J. G. Belton, Dr. J. W. Harman, Mr. J. P. Haughton, Dr. N. A. Porter, Dr. Yasushi Takahashi and Mr. F. G. A. Winder were elected members of the Academy.

The Royal Institution

AT the annual meeting of the Royal Institution, held on May 1, the following officers were elected for the year 1961–62: *President*, Lord Brabazon of Tara; *Treasurer*, Mr. W. E. Schall; *Secretary*, Brigadier H. E. Hopthrow; *Managers*, Mr. F. G. Brown, Sir Harold Roxbee Cox, Mr. E. R. Davies, Prof. Alexander Haddow, Mrs. H. K. Hawkes, Dr. R. Holroyd, Miss E. Henrietta Jebens, Mr. L. B. W. Jolley, Prof. L. A. Jordan, Sir Ben Lockspeiser, Dame Kathleen Lonsdale, Dr. H. Lowery, Mr. W. R. Stevens, Wing-Commander H. F. Tiarks and Prof. W. D. Wright; *Visitors*, Mr. A. D. Baynes-Cope, Mr. A. D. R. Caroe, Mr. Norman Clarke, Miss F. M. Eastwood, Mr. A. H. Ewen, Dr. D. H. Follett, Mr. G. J. Gollin, Mr. N. P. W. Moore, Dr. A. A. Moss, Mr. J. D. Peattie, Mr. Frank Poperwell, Mr. F. Y. Poynton, Dr. H. R. Rishworth, Miss D. Sidebottom and Mr. H. Stanesby.

The Geological Society of London

THE following were elected officers and council of the Geological Society of London at the annual general meeting held at Burlington House, Piccadilly, on April 26: *President*, Prof. S. E. Hollingworth, Yates Goldsmid professor of geology in the University of London; *Vice-presidents*, Prof. T. Neville George, professor of geology in the University of Glasgow; Dr. D. R. Grantham; Sir William Pugh, emeritus professor of geology in the University of Manchester, and lately director of H.M. Geological Survey; Dr. C. J. Stubblefield, director of H.M. Geological Survey; *Secretaries*, Mr. J. M. Edmonds, curator of Geological Collections, University Museum, Oxford; Dr. P. A. Sabine, principal geologist, H.M. Geological Survey. *Foreign secretary*, Prof. O. T. Jones, emeritus professor of geology in the University of Cambridge. *Treasurer*, Mr. P. Evans. *Ordinary members of* *council*, Prof. J. G. C. Anderson (Cardiff), Dr. H. W. Ball (British Museum, Natural History), Prof. K. C. Dunham (Durham), Dr. R. G. S. Hudson (Dublin), Prof. B. C. King (Bedford College, London), Dr. Dorothy Rayner (Leeds), Prof. R. M. Shackleton (Liverpool), Prof. J. Sutton (Imperial College of Science and Technology, London), Prof. P. C. Sylvester-Bradley (Leicester). The following were elected members of the Society: Mr. M. Black, lecturer in geology, University of Cambridge; Mr. P. T. Cox, managing director, B. P. Exploration Co., Ltd.; Mr. D. Curry; Dr. K. A. Davies, deputy director, Overseas Geological Survey; Dr. Vernon Wilson, district geologist, H.M. Geological Survey.

The Franco-British Pharmaceutical Commission

The Franco-British Pharmaceutical Commission was appointed in January 1950 by the Councils of the Pharmaceutical Society of Great Britain and of the Ordre National des Pharmaciens de France to promote co-operation in the field of pharmacy. The formation of the Commission was inspired by the Cultural Convention held by the Governments of France and Great Britain in 1948 at which the hope was raised that " . . . in each country the fullest possible knowledge and understanding of the intellectual, artistic, scientific, technical and educational activities and of the history and ways of life of the other" should be promoted. In the spring of each year since 1951 a team of French lecturers has visited towns in Great Britain, and a British team has gone to France. More recently, British experts have visited France (1960 Lille; 1961 Lyons) to study aspects of the practice of pharmacy there. Three British pharmacists have done research work at the University of Paris, and one is going to Bordeaux during 1961/62. Through the two Societies, the Commission is able to obtain information on most pharmaceutical subjects and to facilitate the exchange of scientific material, for example, specimens of drugs or medicines, between interested parties in the two countries. Week-end congresses, well attended by both French and British pharmacists from all parts of the two countries, have been held in the spring, alternately in France and Great Britain. The ninth Congress, which will be attended by about 100 French and 100 British, is to be held in Jersey during May 12–15, 1961. The secretary of the British Section of the Commission is Sir Hugh Linstead. Further information can be obtained from the Pharmaceutical Society of Great Britain, 17 Bloomsbury Square, London, W.C.1.

Announcements

Prof. John Stanley Griffith of the Department of Chemistry, University of Pennsylvania, has been awarded the Faraday Society's Marlow Medal, for his work on ions of the transition metals.

Dr. Max F. Perutz, director of the Medical Research Council Unit for Molecular Biology, Cambridge, delivered the 1961 Chaim Weizmann Memorial Lecture at the Weizmann Institute of Science, Rehovoth, on April 18, when he was made an Honorary Fellow of the Institute for "his major contribution to the science of X-ray Crystallography applied to macromolecules and for his distinguished part in the elucidation of the hæmoglobin molecule".

The Lawes Agricultural Trust Committee has appointed Dr. C. G. Johnson as head of the Entomology Department, Rothamsted Experimental Station, from October 1, in succession to Dr. K. Mellanby, who will become director of the Monks' Wood Experimental Station of the Nature Conservancy (see p. 488).

The Right Hon. Lord Clitheroe has been appointed a vice-chairman of Tube Investments, Ltd. Sir Ben Lockspeiser, having reached retirement age, and Sir Francis de Guingand have resigned from the Board. Sir Francis is returning to the Union of South Africa, where he will continue to be in charge of Tube Investments interests in Southern Africa. Prof. J. M. Kay, professor of nuclear power at the Imperial College of Science and Technology, University of London, has been appointed to the Board of Tube Investments, Ltd., as director of research and development from July 1.

The Academy of Sciences of the U.S.S.R. has issued two publications in Russia relating to the International Geophysical Year—(1) *Information Bulletin I.G.Y.*, No. 8, 1960. This contains a number of articles and reports on a variety of subjects such as geomagnetism, the ionosphere, glaciology and oceanography. (2) *Bibliography of publications relating to the I.G.Y.* (in Russian). This comprises some 800 items published in 1959, which are ordered and classified according to subjects.

The third international symposium on "Phytopharmacy and Phytiatry" is being held at the State Agricultural University, Ghent, on May 9. Further information can be obtained from the State Agricultural University, Coupure Links, 235, Ghent.

The National Physical Laboratory, Teddington, Middlesex, is organizing two open days during May 10–11. To be included in the programme are two lectures: "The N.P.L. and Industrial Measurement Standards", by Dr. H. Barrell; "Research in the Basic Physics Division", by Dr. J. A. Pople. Further information can be obtained from the Director, National Physical Laboratory, Teddington, Middlesex.

The German Society for Polar Exploration is holding a meeting at Münster during May 11–14. The theme of the meeting will be "New Results in Polar Exploration", and it will include a symposium on "Scientific Problems of Exploring Greenland". Further information can be obtained from the Deutsche Gesellschaft für Polarforschung, E.V., Münster, West Germany.

The International Atomic Energy Agency is organizing an international conference on "Nuclear Electronics", to be held in Belgrade during May 15–20. An exhibition is being organized in conjunction with the conference, and will be open during May 13–21. Further information can be obtained from the International Atomic Energy Agency, Vienna I, Austria.

A meeting of the Biochemical Society is being held in University College and Trinity College, Dublin, during May 25–26. A meeting of the Association of Clinical Biochemists will follow at University College on May 27, and included in the programme is a symposium on "Acid-base Balance". Further information can be obtained from Dr. W. J. Whelan, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1.

THE NATIONAL SCIENCE FOUNDATION, WASHINGTON

ANNUAL REPORT

THE tenth annual report of the National Science Foundation, covering the year ended June 30, 1960*, follows the pattern of the previous two reports. Besides the Director's statement and the chapter reviewing the Foundation's programmes for promoting basic research and education in the sciences (see p. 473) nearly half the report reviews the work of the Foundation during the year. The remaining half of the report consists of appendixes listing the members of the National Science Board, the Foundation's staff, committees and advisory panels, the grants made for basic research and other purposes, fellowship awards, publications, and the financial report.

Grants for research totalled 78 million dollars and the report summarizes briefly the programmes supported through the Foundation's Divisions of Biological and Medical Sciences, and of Mathematical, Physical and Engineering Sciences, its Office of Social Sciences, which for the first time operated for the full year; and, through the Office of Special International Programmes, in the Antarctic. Significant research developments in the year which are noted are the total synthesis of chlorophyll, the study of factors regulating behaviour in man, the discovery of the first synthetic antigen, the isolation and identification of the acetylcholine receptor protein from the electric tissue of the electric eel, the study of gravity response dependent on hereditary factors and the discovery that sub-units of a gene are arranged linearly within a gene. Progress has been made in determining the mechanism of action of vitamin B_{12}, the feasibility of studying bargaining behaviour in bilateral monopoly situations under controlled laboratory conditions has been demonstrated, and an archæological study of eastern Arizona has discovered evidence of a primitive people without pottery and probably without agriculture living in the midst of other tribes with far more advanced culture. A sensitive infra-red analyser has been applied to the measurement of atmospheric carbon dioxide, various isotope techniques are yielding important results in the study of undisturbed cores of sediment from the ocean bottom and a photoelectric image intensifier is giving significant help to astronomers.

Of the 1995 research grants made during the year, 891, totalling nearly 25 million dollars, were for biological and medical sciences; 916, totalling 31·5 million dollars, were for mathematical, physical and engineering sciences; 109, amounting to more than 2 million dollars, for social sciences, and 79, amounting to more than 3·5 million dollars, for Antarctic research.

During the year, in its seven fellowship programmes, the Foundation made 4,010 awards totalling 13·5 million dollars, of which 1,200 were pre-doctoral, 1,190 co-operative graduate fellowships, 580 summer fellowships for graduate teaching assistants, 180 post-doctoral fellowships, 75 senior post-doctoral fellowships, 285 science faculty fellowships for teachers, and 500 summer fellowships for secondary school teachers of science and mathematics. The Foundation also supported 649 institute programmes during the year. Of these, 412 were summer institutes attended by 22,000 teachers; 33 were academic-year institutes for 1,500 teachers and 209 were in-service institutes, attended by some 9,000 teachers on a part-time basis. Special projects in science education included programmes for secondary schools to foster interest in, and understanding of, science, mathematics and engineering, travelling science libraries, grants for visits of outstanding scientists to secondary schools, as well as special science demonstration lectures for secondary schools and a science clubs programme. Other programmes were concerned with undergraduate science education and supplementary training for teachers of science and the improvement of the content of courses.

The Scientific Man-power Programme of the Foundation makes available information on the resources of scientific technical personnel in the United States. A comprehensive report on the status of the scientific and technical man-power register, the Foundation's studies in this field and its projected plans for the future, was issued in January 1960. The Foundation's responsibilities in the dissemination of scientific information have also been extended, and besides endeavouring to improve the existing information services, the Foundation, through its Office of Scientific Information, is promoting a national research programme for developing techniques for handling information. As part of this effort it is vigorously fostering the co-ordination of effort in this field, both within the Federal Government and among private and professional organizations, while on the international level the Foundation has co-operated with the International Federation for Documentation and the Abstracting Board of the International Council of Scientific Unions; and has, with the European Productivity Agency, studied means for establishing a European Translations Centre. Projects in this field assisted during 1960 include a large-scale test programme at Western Reserve University for evaluating procedures developed for the automatic processing and searching of metallurgical literature; a programme on mechanization of processing and searching chemical literature, including research on the semantics of chemical literature; and the investigation of large files of information with a multi-level structure and self-organizing capability at the Electrade Corporation.

The Foundation, mostly through scientific societies, supports the translation, in whole or in part, of 45 Russian periodicals, and, in November 1959, sponsored a conference of editors and officers of 28 professional societies and academic institutions translating such periodicals to discuss means for improving the dissemination of translated periodicals among scientists in the United States. A series of national surveys on media of scientific communication was also launched, and some experiments with new publication techniques and methods were supported. The Foundation is now authorized to support international activities which may improve education in science in the United States.

THE INTERNATIONAL ACADEMY OF ASTRONAUTICS

THE International Academy of Astronautics, which now has a total membership of 76, coming from eighteen countries, was created by the International Astronautical Federation at Stockholm in August 1960, for the purpose of promoting the advancement of astronautical sciences. The Academy is working under a grant from the Daniel and Florence Guggenheim Foundation, and the French Government has provided offices for the Secretariat of the Academy in Paris.

The director of the academy is Dr. Th. von Kármán (United States) and the deputy directors are Prof. J. Pérès, dean of the Faculty of Sciences of the University of Paris, and Dr. F. J. Malina (United States). The initial membership of the Academy included 45 members, mostly leaders in space flight and in sciences related to astronautics. Prof. Niels Bohr has been elected the first honorary member of the International Academy of Astronautics.

The Academy has recently elected the following new members:

Basic Sciences Section: Prof. J. Bartels, University of Göttingen; Prof. D. R. Bates, Department of Applied Mathematics, Queen's University, Belfast; Prof. L. Biermann, director, Max Planck Institute for Astrophysics; Prof. S. Chapman, High Altitude Observatory, Boulder; Dr. H. Friedman, Atmosphere and Astrophysics Division, United States Naval Research Laboratory, Washington; Prof. L. Goldberg, Harvard College Observatory, Cambridge, Mass.; Dr. H. E. Newell, deputy director, Office of Space Flight Programs, National Aeronautics and Space Administration (United States); Prof. F. L. Whipple, Harvard College Observatory, Cambridge, Mass.

Engineering Sciences Section: Dr. A. Busemann, Langley Research Center, National Aeronautics and Space Administration (United States); Prof. E. Carafoli, director, Institute of Applied Mechanics, Bucharest; Prof. L. Crocco, director, Jet Propulsion Center, Princeton University; K. A. Ehricke, Convair Astronautics Division (United States); Prof. A. Ferri, Polytechnic Institute of Brooklyn; Prof. A. R. Kantrowitz, director, Evco Everett Research Laboratory (United States); Mr. M. J. Lighthill, director, Royal Aircraft Establishment, Farnborough; Prof. M. Roy, director, Office National d'Etudes et de Recherches Aéronautiques (France); Dr. H. S. Seifert, Stanford University; Dr. E. Stuhlinger, director, Research Projects Division, National Aeronautics and Space Administration, George C. Marshall Space Flight Center (United States); Dr. Martin Summerfield, Princeton University.

Life Sciences Section: Dr. R. Grandpierre, director, Aviation Medicine Research Center (France); Prof. U. S. von Euler, Department of Physiology, Karolinska Institutet; Dr. A. Graybiel, director of research, U.S. Naval School of Aviation Medicine (United States); Prof. T. Lomonaco, director, Research Centre for Aviation Medicine (Italy); Prof. R. Margaria, former director, Research Centre for Aviation Medicine (Italy); Dr. H. J. Schaefer, Research Department, United States Naval School of Aviation Medicine; Prof. G. Schubert, Physiological Institute, University of Vienna; Colonel J. P. Stapp, Aerospace Medical Center, Brooks A.F. Base (United States); Air Commodore W. K. Stewart, Royal Air Force Institute of Aviation Medicine, Farnborough; Dr. P. M. Van Wulften Palthe, National Aeromedical Centre (Netherlands); Sir Harold E. Whittingham, Chief Medical Officer, British Overseas Airways Corporation.

The next meeting of the Academy will be held in October 1961, in Washington, in conjunction with the annual congress of the International Astronautical Federation. During the meeting, the first Daniel and Florence Guggenheim International Astronautics Award will be presented. This international prize of £1,000 is to be given annually to an individual who has made outstanding contributions to astronautics during the five preceding years. The Academy will also review the work of the following committees: Publications, Awards and Fellowships, Lunar International Laboratory (LIL), and the Joint Commission of the Academy and the International Institute of Space Law on Technical Aspects of Space Law.

APPLIED BIOLOGY IN TECHNICAL COLLEGES

DEVELOPMENTS in the courses leading to the Diploma in Technology in Applied Biology at Bristol College of Science and Technology and at Brunel College of Technology, Acton, are described in the *Journal of the Institute of Biology* (8, No. 1; Jan. 1961).

The Diploma in Technology course in Applied Biology at Bristol began in October 1957 with eleven students, all college based. A previous survey had shown that opportunities for botanists and zoologists were very limited, but that there were increasing opportunities for trained biologists in the field of microbiology, pharmacology and biochemistry. The course was, therefore, arranged as a sandwich course for college-based students, designed to give a broad training in the early years with opportunity for specialization in the final year. As approved eventually by the National Council for Technological Awards, the course requires the study of botany, zoology, microbiology, physiology and chemistry in the first three academic periods in college, followed by biochemistry with a choice of either plant pathology, plant physiology, pharmacology, microbiology or entomology as a specialization in the final year, as well as a project occupying on average one day per week. General studies and tutorial work are an essential feature of the course.

The annual intake to the course is limited to between fifteen and twenty students. No student is admitted without interview, and, where it is felt that an insufficient number of suitable candidates present themselves, no attempt is made to fill the course; academic qualifications required for entry are either two Advanced Level passes at the General Certificate of Education, or a good endorsed certificate in biology, but at least equal emphasis is placed on personality. Applications for admission to the course are now coming forward at the rate of fifty to sixty each year; of these a high percentage is made up of students who have been offered university places, but have preferred a course leading to a Diploma in Technology. At the same time, some students withdraw their applications on being offered university places, although this happened only in one case during 1960. There has been some wastage on the course arising from a variety of causes.

Co-operation with industry has been very close, and, during the three years for which the course has now been running, staff have been cordially received during their industrial visits. Some thirty-five firms offer industrial training at various levels and in various fields, and a number of other firms are anxious to co-operate as student numbers grow. Before a student is assigned to a particular firm, his or her interests are discussed with the head of department and the senior lecturer in biology, and the advice of various lecturers sought; an approach is then made to the firm able to offer the most appropriate kind of training and a suitable programme is drawn up. The student is then called for interview by the selected firm and a final decision is made as to the general suitability of arrangements. A member of staff from the firm is chosen to supervise the industrial training and to maintain contact with the College.

A tutor visits the student on two or three occasions, and mid-way through these industrial periods students are brought together for a residential week-end at some selected college outside Bristol, along with students from other Diploma in Technology courses. This provides an opportunity to meet the College staff and discuss matters of general interest.

The break of six months in academic work presents problems of continuity. Difficulties are to a considerable extent overcome by close consultation between industry and the College. Students leave college with some academic assignments involving guided reading and the writing of essays. Every care is taken to ensure that this does not create too much of a burden by holding a staff meeting at which the amount of work to be given to students is finally determined. Details of the assignments are given to the industrial tutors so that they are fully aware of the work to be done by a student during the industrial period; in some cases, time to do this work is allowed for in the general programme. Over and above this, a student is required to write an account of the industrial training and of its relevance to the particular industry in which he finds himself.

This course, despite some initial difficulties, is proving to be of considerable value to students, and, while there is still room for experimentation, the general pattern is sound. All the present fourth-year students are assured of appointments on completing their course, and an increasing number of firms are willing and anxious to co-operate.

The course for the Diploma in Technology in Applied Biology also began at the Brunel College of Technology in October 1957; and, although the subjects studied differ in detail from those at Bristol, the general arrangements follow the same pattern

TREE PLANTING IN THE NATIONAL PARKS

A PUBLICATION has recently been issued jointly by the Standing Committee on National Parks of the Councils for the Preservation of Rural England and Wales and the Joint Action Group for the Protection of Dartmoor and Exmoor, entitled *The Case for Control of Afforestation of Open Land in National Parks**.

The problem of land use in our heavily populated island becomes yearly more and more complex. The public memory is short, and even those who are capable of pre-vision and of determining what is desirable in the long run cannot convince Governments of the appropriate action. This is especially true of tree-planting in its various aspects. Apart from a fraction of the land-owning class of earlier centuries it is unfortunately true that those in control have always been uninterested in, even antipathetic to, forestry as a commercial undertaking at home—so long as there existed readily available supplies of timber abroad. But for the lessons of two World Wars it is very doubtful if a State forest service would ever have been set up in Great Britain with the task of creating new forests and conserving existing woodlands. Since its establishment in 1919, the Forestry Commission has made good progress with its main task and its activities are widespread over most of Britain. It has clashed here and there with various land users, but, on the whole, its work is appreciated.

It would be wrong to imagine, however, that the Government has some overall plan for land use and that the various authorities who have an interest in land use are centrally controlled. It is not even the case that all the statutory authorities concerned in any way with tree conservation, tree-planting, afforestation and forestry are centrally controlled. Besides the Forestry Commission, in Britain, the following public bodies are interested in trees in one way or another—the local planning authorities under the Town and Country Planning Act of 1947, the Nature Conservancy, and the National Parks Commission. In addition, there is now the Timber Growers Association of private individuals engaged in commercial tree-planting enterprises. In some respects their interests clash, especially when the problem of conservation of amenities arises.

It is not a good thing that the various bodies interested in woodlands for various reasons should quarrel among themselves; they should be in the closest association, so that the woodland heritage can be preserved and extended, wherever possible, to fulfil to the best advantage all the recognized functions of protection, amenity, recreation and production. Hitherto, the tendency has been for

* Standing Committee on National Parks and Joint Action Group *The Case for Control of Afforestation of Open Land in National Parks*, presented by the Standing Committee on National Parks of the Councils for the Preservation of Rural England and Wales; and the Joint Action Group for the Protection of Dartmoor and Exmoor. Pp. 24. (London: Standing Committee on National Parks, 4 Hobart Place, S.W.1, 1961.)

State action to concern itself too much with the commercial aspect of tree-planting. Afforestation has been almost entirely directed towards the establishment of short term 'crops' of trees and not to permanent woodlands adapted to satisfy demands for amenity, recreation and protection. In harmony with this tendency special fiscal concessions are given to private woodland owners who engage in commercial forestry. Taxation, in relation to tree-planting in Britain, is not easy to understand, more especially as the tree grower is also entitled to certain grants in aid. The Government takes with one hand and gives with the other, and it is not very clear why. A case can be made for State assistance to recreate forests, and a case can be made for a simple single basis of taxation of commercial forests, namely, on the profits of the enterprise instead of on the timber capital; but it is extremely difficult to segregate the commercial forest from the amenity woodland and to say how the State should act in relation to the latter. The ideal woodland is that which fulfils the triple functions of protection, amenity and production, and many landowners could teach the Forestry Commission a lesson to that effect.

The fiscal concessions allowed to tree-growers have led to a striking and relatively recent development in forestry circles. Commercial afforestation enterprises have been set up and have become especially active in southern England and Wales. The task which they have set themselves would not be financially attractive—it would not be economic—without the subsidies and fiscal concessions at present allowed. How successful these afforestation enterprises will be eventually, that is in the establishment of healthy permanent woodland, remains to be seen. Like the greater part of the Forestry Commission plantations they are, taking the long view, still experimental. If they pay the entrepreneurs it is solely because of the State assistance and taxation reliefs.

The position in respect of subsidies for tree-planting and of taxation relief to woodland owners certainly requires to be reconsidered; but whether it is desirable to give the Standing Committee on National Parks over-riding control on afforestation in such a way as to conflict with the duties of the Forestry Commission, or in any other way, is very doubtful.

The case for establishing such a control is put in a memorandum distributed by the Standing Committee on National Parks of the Council for the Preservation of Rural England and Wales and the Joint Action Group for the Protection of Dartmoor and Exmoor. They view with alarm the incursion of commercial afforestation into the Dartmoor and Exmoor National Parks in particular. They have a case. The solution does not lie, however, in resisting such encroachments but in trying to ensure that the State assistance on which the intruders depend is devoted to the creation of a type of forest which increases the amenities of the Parks while at the same time being productive.

There is no reason why the creation of these woodlands should result in the "squandering of any noble heritage of beauty" except in so far as the methods adopted are inappropriate. It is unfortunate that until recently State forest policy had subordinated too much the important protective and amenity functions of woodlands to the purely commercial function of producing timber, because it has placed the Forestry Commission in a weak position when it comes to discussing the best use of tree-planting associated with national parks.

In respect of Britain as a whole there are many districts where an afforestation policy of this kind would be welcomed, and which might benefit greatly from what is in effect the local expenditure of taxation revenues indirectly through the medium of private enterprise. Whether this is really a healthy development from the point of view of forestry is another matter. The production of figures in a book is a very different skill from that of creating and conserving a forest on the ground.

M. L. Anderson

PARENTS' VIEWS ON EDUCATION

During the past three years Political and Economic Planning has been carrying out an inquiry to determine how far the social services are meeting the needs of the people who use them.

Of the social services none can affect the life of the individual and the nation more radically than education, and, as a preliminary to a fuller report to be published later, Political and Economic Planning has produced a broadsheet recording the findings of the inquiry on the education service*. Since the object of the survey was to present the consumers' view of the social services, the broadsheet's approach to the education service must necessarily be a limited one. Parents' wishes cannot be equated with educational need. Parents may over-rate their children's abilities, or they may not understand what the school is trying to do. Nevertheless, it is part of the new plan for education that the parent should become more closely involved in the child's schooling. An understanding of parents' experience and opinions is, therefore, essential when considering the present achievements of the education service.

The main inquiry was carried out among families living in the Greater London area. It had been decided that the inquiry must be concentrated in one district and that the locality chosen should be a large urban area since this is the type of community in which most people live. It should also be large enough to contain a diverse population and to include several local authority areas with a variety of different arrangements for some of the social services. Greater London fulfilled all these requirements. To make sure, however, that the findings for London were not untypical of the rest of Britain, a second smaller inquiry was carried out in Northampton, a provincial town of quite different size. This second inquiry confirms that the London findings can be considered representative. A total of 734 families was successfully interviewed in the main inquiry. Since the social services to-day are not primarily concerned with hardship, or important only to limited sections of the population, it had been decided to study samples of all families with children under the age of 16.

---

* *Planning*, Vol. 27, No. 448 (January 23, 1961): Parents' Views on Education. Pp. 1–32. (London: Political and Economic Planning, 1961.) 3*s*. 6*d*.

It is evident from the answers received during the survey that there is now considerable interest in education and appreciation of its possibilities. The mothers showed concern with the kind of school attended by their children, and they had often decided that there was some particular form of higher education or specific training that they would like their children to have. A high proportion of those with older children said that they wanted them to stay at school after they were fifteen. Although interest was greatest at the top of the occupational scale, it was also strong among the operative groups. It would appear that the attitude towards education at all levels of society is becoming more positive. A higher standard of living together with smaller families has lessened the necessity for working-class parents to turn the child into a wage-earner as soon as possible. Instead, there is a wider realization that educational qualifications may be a valuable investment and that very wide opportunities may be open to the talented child. The old grudging attitude towards the school as a place in which children were detained when they might usefully have been out at work appears to be dying.

Although the prevailing attitude towards the education service is not an unfavourable one, there is a substantial section of unsatisfied demand for particular schools. There was no intention during the inquiry to set up arbitrary standards in the field of education and to test whether or not these were reached in the families in the sample. Nevertheless, it was a general principle in the Education Act that parents should be able to get the kinds of schools and education for their children that they think the children need. Altogether 17 per cent of the mothers in the inquiry said that they had failed to get particular types of school that they had wanted. Six per cent were thinking of nursery schools and 7 per cent of secondary schools (mainly grammar and technical). There may be differing views on whether or not there is a real need for these services as distinct from a demand for them; the need for expansion and improvement in these two fields has already been accepted by the community and incorporated in the Education Act of 1944. While the proportions of present-day demand are small in comparison with the total sample, they are considerable when compared with the proportions who had used the types of school in question. (Five per cent of the families had used nursery schools, 12 per cent grammar schools and 6 per cent technical schools.)

The demand for grammar and technical schools and also, in some cases, the use of private schools, appears to be the result of parents' dissatisfaction with secondary modern schools. Some of their comments suggest that they regard the secondary modern school as offering inferior academic education and as not providing a specific enough training for a particular job. If the objects of the 1944 Education Act are fully realized and secondary modern schools come to be recognized as enjoying the equality of facilities and staffing with grammar schools, it seems possible that the demand for grammar schools may decrease. Similarly, if secondary modern schools play their part in the provision of technical education then parents are less likely to feel that their children are missing opportunities for occupational training. The present situation, in which certain secondary schools are obviously considered superior to others, is socially undesirable and harmful to the successful as well as the unsuccessful children.

It is important, however, that parents should be able to arrange for a grammar school place for those children who should benefit from it. One feature that emerges from the Political and Economic Planning survey is that at present the education service is being used most advantageously by families at the top of the social scale. The managerial and professional group and the supervisory and technical group have been more successful than others in obtaining grammar school places for their children. It is the managerial and and professional group that shows the strongest awareness of education.

The desire for further information is strong among the other groups, however, and the disparate use of the service cannot be entirely accounted for by less interest in education among these groups. When parents at the bottom of the occupational scale would prefer a grammar school place for their children they are, nevertheless, less likely to obtain it. It seems that there are a number of parents failing to get the education they would like for their children because the education itself is beyond their own experience.

The demands which parents make on the education service on behalf of their children may sometimes be unreasonable or because they are inadequately informed. On one hand, parents may identify their own social prestige too closely with their children's achievements or, on the other hand, they may be too little aware of the ends and means of education. It appears, for example, that the mothers questioned in the survey were concerned predominantly with the jobs their children would get and not with the enrichment of their personality. Nevertheless, it is important that parents should feel reasonably satisfied with their children's education.

TERRESTRIAL SPECTROSCOPY

By Prof. C. L. PEKERIS, Z. ALTERMAN and H. JAROSCH

Department of Applied Mathematics, The Weizmann Institute, Rehovot, Israel

THE discovery of the Zeeman effect in 1896 came at a time when the basic concepts needed for its interpretation had been worked out by Lorentz[1]. Already in his first paper[2], Zeeman reported a verification of the polarization of the lines, an effect which Lorentz had advised him to look for. He gives a derivation, on the basis of the Lorentz theory, of the formula for the splitting of the original frequency σ_0 by a magnetic field H:

$$\sigma = \sigma_0 \pm \frac{eH}{2mc} \qquad (1)$$

This relation had been derived independently by Larmor. Larmor proved[3] that the effect of a magnetic field on the orbit of a charged particle is analogous to the effect of rotation on the frequency of a mechanical system. While the Zeeman effect provides ample verification of the electromagnetic part of Larmor's analogy, an experimental demonstration of the mechanical counterpart has been wanting. A striking case of the splitting of the natural frequency of a purely mechanical system by rotation presented itself recently when the records of the Great Chilean earthquake of May 22, 1960, were analysed. This earthquake excited the natural oscillations of the Earth. The gravest modes $n = 2$ (53·7 min.) and $n = 3$ (35·5 min.) appeared as doublets in the spectra of both the gravimetric records[4] and the strain-meter records[5].

The free oscillations of the Earth are governed by gravitational and elastic forces. Taking the distribution of density $\rho(r)$, and of the elastic constants $\lambda(r)$ and $\mu(r)$, as inferred primarily from seismic as well as from other geophysical data, we have determined the terrestrial spectrum for several proposed models of the Earth[6-9]. The periods deduced from spectral analysis of the strain-meter records (52 lines) agreed with the gravimetric values (49 lines) to within 1 per cent; and this was also the measure of agreement with the theoretical spectrum[9] for the Gutenberg model of the Earth, and to a lesser extent with the spectrum for the Bullen *B* model. Free modes ranging from spherical harmonic order $n = 2$ up to $n = 38$ were identified seismically, and up to $n = 41$ gravimetrically.

We have investigated the effect of rotation on the spectrum of the Earth by carrying out a first-order perturbation calculation in the parameter $\alpha = \omega/\sigma_0$, where ω denotes the angular rotation of the Earth. In the absence of rotation, the components of displacement u_0, v_0 and w_0 in a spherical system of co-ordinates (r, θ, φ) are given by:

$$u_0 = U_0(r)Y_{nm}, \quad v_0 = V_0(r)\frac{\partial}{\partial\theta}Y_{nm} \tag{2}$$

$$w_0 = \frac{V_0(r)}{\sin\theta}\frac{\partial}{\partial\varphi}Y_{nm}, \quad Y_{nm}(\theta, \varphi) = P_n^m(\cos\theta)\exp im\varphi \tag{3}$$

where a factor $\exp i\sigma t$ has been omitted. The characteristic frequencies $\sigma_0(n)$ are degenerate, and do not depend on the azimuthal number m. The introduction of a slow rotation $\omega(\ll\sigma_0)$ removes the degeneracy, each line $\sigma_0(n)$ being split into $(2n + 1)$ lines σ_n^m given by:

$$\sigma_n^m = \sigma_0(n) + m\tau(n)\omega \qquad -n \leqslant m \leqslant n \tag{4}$$

with

$$\tau(n) = \frac{\int_0^a \rho r^2(2U_0V_0 + V_0^2)dr}{\int_0^a \rho r^2[U_0^2 + n(n+1)V_0^2]dr} \tag{5}$$

in the case of spheroidal oscillations, and

$$\tau(n) = \frac{1}{n(n+1)} \tag{6}$$

in the case of torsional oscillations.

Table 1 gives the periods in the multiplets for the oscillations of spherical harmonic order $n = 2$ and 3 of the Bullen *B* model. These are based on the previously determined values[7] of $\sigma_0(n)$, and on equations (4) and (5). Also shown are theoretical intensities of the gravimetric and strain-meter lines for an observing station at Los Angeles ($\theta = 56°$). These were determined on the assumption of an explosive compressional point-source at the earthquake focus in Chile ($\theta_0 = 128°$).

Table 1. THEORETICAL AND OBSERVED MULTIPLETS FOR LOS ANGELES. $\theta = 56°$

n	m	T min.	Amplitude		Observed periods	
			Gravimetric	Strain	Gravimetric (ref. 4)	Strain (ref. 5)
2	−2	55·33	0·115	0·302	54·98	
2	−1	54·50	0·242	0·615		54·7
2	0	53·70	0·0015	0·0023		
2	1	52·92	0·242	0·615	52·80	53·1
2	2	52·15	0·115	0·302		
3	−3	35·99	0·396	0·401		
3	−2	35·83	1·257	1·46	35·87	35·9
3	−1	35·67	0·282	0·377		
3	0	35·50	0·624	0·873		
3	1	35·34	0·282	0·377		
3	2	35·18	1·257	1·46	35·24	35·2
3	3	35·03	0·396	0·401		

As for the periods, the feature of interest is the observed interval between the doublets, rather than the central frequency, since the latter depends on the particular Earth model assumed. We note the following:

(1) *Gravimetric.* In the case $n = 2$, the central line $m = 0$ should be very weak, and was actually not observed. The theoretical interval between the strongest $m = -1$ and $m = 1$ lines is 1·6 min., as against the observed interval of 2·2 min. Since, however, the $m = \pm 2$ lines are theoretically half as strong as the $m = \pm 1$ lines, the observed lines may represent the unresolved pairs $m = 1$ and 2. The average periods of the pairs, weighted according to their amplitudes, are 54·77 min. and 52·67 min., giving an interval of 2·1 min., which is close to the observed interval of 2·2 min.

In the case $n = 3$, the strongest lines should be the pair $m = \pm 2$, which are very close to the observed two lines. The $m = 0$ line should be half as strong, and should have been observed if the noise-level were low enough and the resolution adequate.

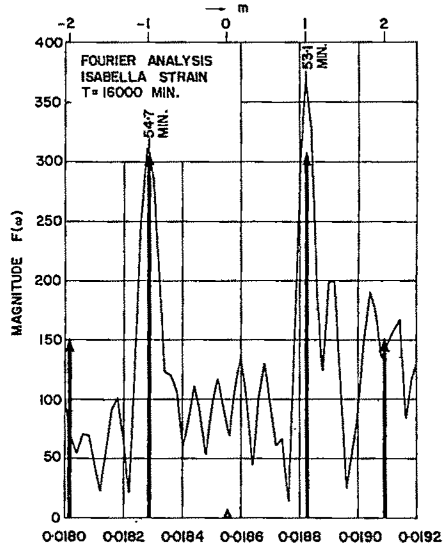

Fig. 1. $n = 2$. Arrows show positions and amplitudes of multiplet. ——, Spectral intensity of Chilean earthquake observed at Isabella by Benioff, Press and Smith (ref. 5)

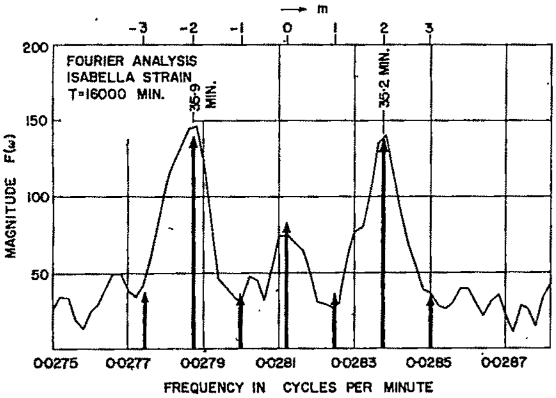

Fig. 2. $n = 3$. Arrows show positions and amplitudes of multiplet. ——, Spectral intensity of Chilean earthquake observed at Isabella by Benioff, Press and Smith (ref. 5)

In addition to the doublets in the fundamental $n = 2$ and $n = 3$ modes, the first overtone of the $n = 3$ mode was also reported[4] as a gravitational doublet: $T = 17{\cdot}88$ min. and $17{\cdot}68$ min. Theoretically, the relative amplitudes within a multiplet for the overtones should be the same as for the fundamental, as given in Table 1. The strongest lines in all the overtones of $n = 3$ should therefore be again the pair $m = \pm 2$. The period-interval for the pair comes out 0·19 min., in agreement with the observed value of 0·2 min.

(2) *Seismic*. Two doublets were reported by Benioff, Press and Smith[5] from a Fourier analysis of the strain seismogram at Isabella, California. In Fig. 1 is reproduced their spectral intensity curve in the vicinity of the $n = 2-$ pair of 54·7 min. and 53·1 min. In the same diagram are shown, by arrows, the theoretical separations and amplitudes of the five lines making up the $n = 2$ quintet, in accordance with the results given in Table 1. The central $m = 0$ line should be extremely weak, and is indeed below the background noise. The $m = 2$ line is not far from the observed intensity-level. On the other hand, the $m = -2$ line is definitely above the observed intensity in its vicinity. One would expect a rise in intensity immediately to the left of this line, which is outside the limit of the figure.

In Fig. 2 are shown the observed spectral curve for $n = 3$, and the theoretical positions and amplitudes of the $n = 3$ septet. The central $m = 0$ line is defined, and its theoretical intensity is close to the observed value. The $m = \pm 1$ and ± 3 pairs are close to the general noise-level in their respective neighbourhoods.

It is seen that, in general, the doublets observed are those lines of the multiplet which are strongest theoretically, and that the missing lines would not be expected to stand out above the observed noise-level.

This investigation was supported by the Office of Naval Research and Project VELA-UNIFORM of the Advanced Research Projects Agency.

FLUORESCENCE OF TETRACYCLINES IN BONE TUMOURS, NORMAL BONE AND TEETH

By L. N. OWEN

Department of Veterinary Clinical Studies, University of Cambridge

FOLLOWING the observations on the localization of the tetracyclines in bone by Milch, Rall and Tobie[1], other workers have used the tetracyclines as bone markers and have also studied under ultra-violet light the fluorescence produced by these compounds in various pathological lesions, including bone tumours and other neoplasms. Some recent investigations on this subject are described in this communication and will be published in detail elsewhere.

The source of ultra-violet light was a Wood's mercury vapour lamp as used in the diagnosis of ringworm. Photographs were made on high-speed Ektachrome film using a Wrayflex camera, with a Wratten 2*E* filter, with the object at about 30 cm. distant from both the light source and the camera. Exposure times were usually about 4 min. A Leitz fluorescence microscope with a Philips 150-watt mercury vapour lamp was used for the histological examinations.

A group of rats, seven weeks old, was subjected to fracture of the left tibia with the intact fibula acting as a splint during repair. Animals were killed at intervals of 3 days. 24 hr. before death they were injected intraperitoneally with chlortetracycline. Yellow orange fluorescence could be detected in the fracture callus from the ninth day onwards. When young rats with deep yellow-orange fluorescent bones due to previous administration of chlortetracycline were subjected to fracture of the tibia and no more chlortetracycline administered the resulting callus, in contrast to the fracture fragments, showed no fluorescence. Following the injection of chlortetracycline into older rats with osteomyelitis of the femur the new bone fluoresced yellow while the older normal bone showed only blue autofluorescence. Normal bone laid down in drill holes made in the femur a year previously did not fluoresce.

Sarcomata produced 8 months after implantation of methylcholanthrene crystals into drill holes made in the femur of rats showed no fluorescence, but roughened areas of new bone adjacent to the original drill holes fluoresced bright yellow. Osteosarcomata *D*177 showed yellow fluorescence, but the bones of these animals showed only normal blue autofluorescence. Sarcomata produced by the sub-cutaneous implantation of plastic disks 2 cm. in diameter did not fluoresce.

Normal rats about 19 days pregnant were injected intramuscularly with chlortetracycline and killed 24 hr. later. Gross examination of the fœtuses showed marked yellow fluorescence in both 'membrane bone' and 'cartilage bone' demonstrating crossing of the placental barrier by the drug. Young female rats dosed heavily with chlortetracycline prior to mating and the bones of which fluoresced bright orange-yellow under ultra-violet light produced fœtuses the bones of which showed no fluorescence.

A normal dog, eight weeks old, was dosed regularly with 750 mgm. chlortetracycline on six days a week for a month. Following eruption of the permanent teeth these appeared pale yellow in daylight as compared with the teeth of normal litter mates, and there was intense yellow fluorescence under ultra-violet light. On histological examination both dentine and enamel were found to fluoresce. Four narrow bands of non-fluorescent dentine occurred in the wide band of fluorescent dentine and probably correspond to the Sundays when no chlortetracycline was administered (Fig. 1).

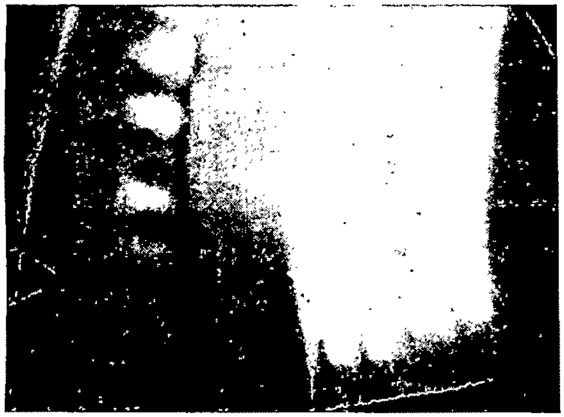

Fig. 1. Section of incisor tooth of dog showing fluorescence of Schreger's lines of the enamel (left) and fluorescent bands in the dentine (right), following chlortetracycline administration (× *c*. 30)

Chlortetracycline was administered to a 5-month old Great Dane with a condition indistinguishable from osteogenesis imperfecta. Examination of the bones at death three days later showed the very thin cortices to fluoresce in a similar manner and intensity to that seen in young dogs with normal thickness of cortex. The epiphyseal line showed normal blue autofluorescence.

A Great Dane weighing 60 kgm. and with spontaneous osteosarcomata of the distal radius and ulna in both fore limbs had previously had these limbs perfused with nitrogen mustard, using an extracorporeal circulation[2]. An increase in size of the tumour in the right radius was noted 5 months later and the animal was killed. About 18 hr. prior to killing 1 gm. of chlortetracycline hydrochloride was given intravenously and 1 gm. orally but an unknown quantity of the oral dose was later lost by vomiting. On post-mortem examination brilliant yellow fluorescence was seen under ultra-violet light in the area of new bone in the tumours of the fore limbs both in the medullary cavity and as extensions from the periosteum (Fig. 2). This fluorescence was much brighter than the orange fluorescence which has been observed in fracture callus of dogs following administration of tetracyclines. Areas of non-osteogenic tumour tissue, which were of a rubber-like consistency, did not fluoresce. Normal bone adjacent to the tumour showed only blue autofluorescence. Brilliant yellow fluorescence also occurred in the osteogenic areas of a metastasis in the right axillary lymph node (Fig. 3) and in a small and previously unsuspected area of malignant new bone in the left tibia. This latter area was difficult to detect in daylight but under ultra-violet light the narrow band of yellow fluorescence was very striking. Two small metastases in the lungs, undetectable by radiography, did not fluoresce, and on microscopical examination were found to consist solely of sarcoma cells with no osteogenic tissue. The only normal soft tissues showing appreciable fluorescence were the testicles, which showed a dull yellow fluorescence tinged with green.

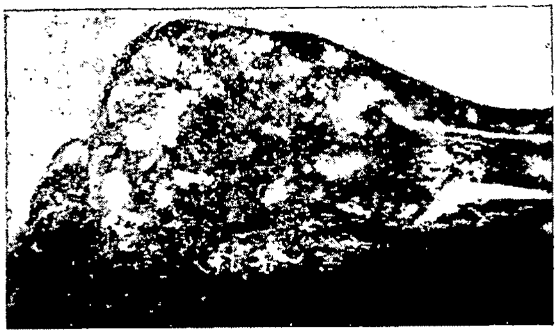

Fig. 2. Longitudinal section of the right distal radius of a Great Dane showing fluorescent areas of new bone in the osteosarcoma. The adjacent normal bone showed no yellow fluorescence but is clearly visible on the photograph because of its normal blue autofluorescence. (× *c*. 1/3)

A greyhound with an osteosarcoma of the proximal tibia was injected intravenously with tetracycline hydrochloride (20 mgm./kgm.) and four days later was killed. Yellow-orange fluorescence was particularly noticeable on the large new areas of bone attached to the tibia but also occurred in smaller osteogenic areas in the tumour tissue. Other tissues showed no similar fluorescence and no metastases were discovered in this dog.

Fluorescence of tetracyclines in new bone as opposed to normal soft tissues in dogs persists for

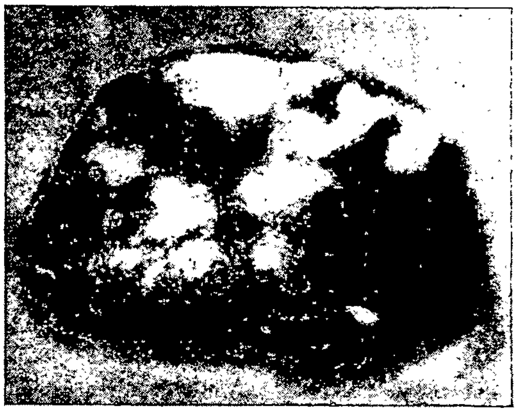

Fig. 3. Section through the right axillary lymph node of the same dog showing fluorescent areas of tumour bone. (× *c*. 3)

long periods of time. Older normal bone shows only blue autofluorescence. It would therefore seem possible that if tetracycline labelled with iodine-131 had been administered to the Great Dane with multiple osteosarcomata confirmation of a metastasis in the axillary lymph node would have been obtained. The scintillation counter would also have discovered the new focus of malignancy in the tibia but not the small non-osteogenic areas in the lungs.

Further work is planned to develop the therapeutic possibilities of radioactive or other destructive agents attached to the tetracycline molecule.

Rats bearing osteosarcoma $D177$ were generously supplied by Prof. Alexander Haddow from the Chester Beatty Cancer Research Institute. Lederle Laboratories, Ltd., gave the chlortetracycline ('Aureomycin') and tetracycline ('Achromycin'), and I am particularly grateful to Dr. Ruth Porter for arranging this and for her help in this investigation. Mr. A. R. Jennings kindly confirmed the diagnosis of the tumours.

EFFECTS OF OLIGOMYCIN ON RESPIRATION AND SWELLING OF ISOLATED LIVER MITOCHONDRIA

By Dr. J. B. CHAPPELL* and Dr. G. D. GREVILLE†

Department of Biochemistry, University of Cambridge

INTACT liver mitochondria oxidize substrate rapidly only when in the presence of adenosine diphosphate (ADP) or of an uncoupling agent such as 2 : 4-dinitrophenol (DNP). Since oligomycin inhibits oxidations of pyridine nucleotide-linked substrates in presence of the former and the inhibition is reversed by the latter, Lardy and his colleagues[1] have concluded that this antibiotic interferes with the enzyme system responsible for respiratory-chain phosphorylation. This is strengthened by the finding that it inhibits mitochondrial DNP-stimulated adenosine triphosphatase and the adenosine triphosphate – inorganic phosphate exchange, both of which are thought to involve enzymes of the phosphorylation system of the respiratory chain; it also prevents the loss of oxygen-18 from labelled inorganic phosphate. These further observations indicate that oligomycin acts on that part of the phosphorylation system which is involved in the uptake of inorganic phosphate.

Oligomycin has also been found to prevent the swelling of rat-liver mitochondria induced by inorganic phosphate, and DNP reversed this effect[2]. This seemed to be in conformity with the proposal[3,4] that swelling of this type occurs only when some measure of electron transport is proceeding. Since, however, the observations on swelling were made with media containing sucrose (0·3 M), which markedly inhibits the oxidation of some substrates[5], it was desirable that these latter effects of oligomycin should be re-investigated.

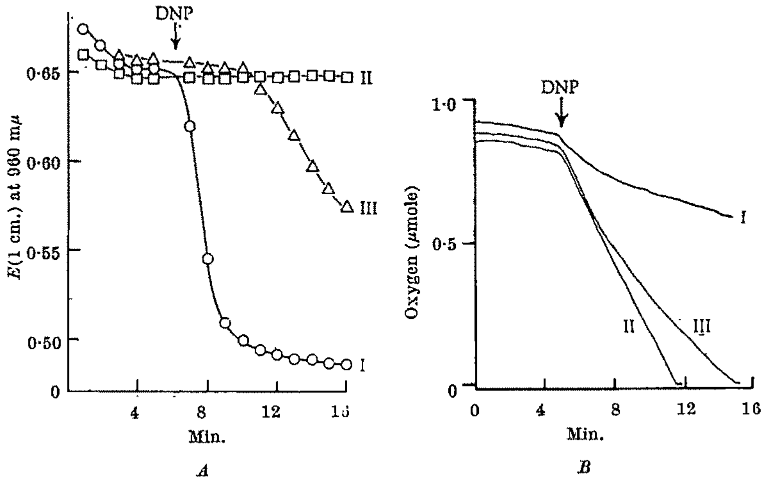

Fig. 1. Swelling (*A*) and respiration (*B*) of rat-liver mitochondria in presence of L-glutamate. In all runs, oligomycin (0·6 μgm./ml.) was present throughout and 2 : 4-dinitrophenol (0·04 mM) was added 5 min. after mitochondria (arrow). I, no adenine nucleotide added; II, 0·33 mM adenosine diphosphate added before mitochondria; III, 0·33 mM adenosine triphosphate added before mitochondria. Mitochondrial nitrogen, 0·11 mgm./ml. Other constituents of medium as in text. Total volume, *A*, 3 ml.; *B*, 4 ml. Temp. 25° C.

In a medium (pH 7·4) containing 80 mM potassium ions, 6 mM magnesium ions, 27 mM 2-amino-2-hydroxymethylpropane-1 : 3-diol, 92 mM chloride ions, 16 mM inorganic phosphate and 10 mM L-glutamate, and with the sucrose reduced to about 5 mM, oligomycin again prevented swelling, and subsequent addition of DNP initiated it. However, in the presence of ADP this effect of DNP was not seen; that is, with oligomycin present, a rapid swelling was caused by DNP alone but not by DNP together with ADP (Fig. 1*A*). Simultaneous measurements of respiration with the Clark oxygen electrode (technique to be described by J. B. C.) under identical conditions showed that, in the absence of adenine nucleotide and presence of oligomycin, respiration was not maintained after addition of DNP, but that addition of ADP before or shortly after the DNP prevented this decline in respiratory-rate (Fig. 1*B*). Adenosine triphosphate temporarily prevented the swelling induced by DNP in the presence of oligomycin and, also for a short period, the fall in respiration; we judge these effects to be due to ADP derived from the added triphosphate. If a very small amount of ADP is added after the DNP, the decline in respiratory-rate is delayed for only a short time: repeated small additions of ADP result in a stepwise curve (Fig. 2). Thus mitochondria treated with oligomycin

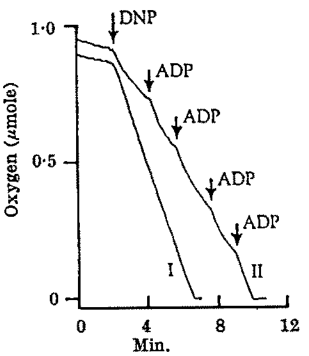

Fig. 2. Respiration of rat-liver mitochondria in presence of L-glutamate. 2 : 4-Dinitrophenol (0·04 mM) added at time shown by arrow. I, no addition of oligomycin or adenine nucleotide; II, oligomycin (1·2 μgm./ml.) present throughout, and additions of adenosine diphosphate as shown (12 μM in the first three and 24 μM in the last). In both runs, mitochondria equivalent to 0·2 gm. of liver in 4 ml. total volume: 1 mM ethylenediamine tetraacetate; other constituents of medium as in text. Temp., 25° C.

show some measure of respiratory control despite the presence of DNP. Results similar to those in Fig. 1*A*, *B* were obtained with ferricyanide instead of oxygen as terminal acceptor. The reduction of ferricyanide was followed by means of a smooth platinum electrode and automatic titrator (Radiometer, Copenhagen) (unpublished work by G. D. G. and J. B. C.).

Thus, in presence of oligomycin and DNP and with glutamate as substrate, ADP both maintains respiration and prevents swelling. The decline in respiratory-rate in the absence of adenine nucleotide appears to result from failure of the oxidation of the α-ketoglutarate formed from the glutamate, insufficient ADP being available for the obligatory phosphorylation at the substrate-level. The requirement for ADP when DNP is present is most likely to be related to this stage in the tricarboxylic acid cycle, since when the substrate was changed to β-hydroxybutyrate, L-malate, L-proline or succinate, addition of ADP was no longer necessary for the maintenance of rapid respiration. In fact, of the substrates tested, only glutamate, $L_s(+)$-*iso*citrate and α-ketoglutarate showed the requirement for ADP. When succinate was substrate, in order to obtain rapid oxidation uninhibited by accumulation of oxaloacetate, amytal was added to inhibit oxidation of malate. When malate was substrate, oxaloacetate was removed by transamination with glutamate, β-chlorovinyl arsenious oxide (lewisite oxide) being added to stop oxidation of the glutamate and α-ketoglutarate (see later).

It can be deduced therefore that, with DNP present, ADP is not required for the oxidation of mitochondrial reduced pyridine nucleotide. The oxidation of α-ketoglutarate, on the other hand, requires ADP for the associated substrate-level phosphorylation. The ADP requirement for the oxidation of glutamate and *iso*citrate may be ascribed to the circumstance that these give rise immediately to an α-ketoglutarate. This implies that oxidation of glutamate and *iso*citrate cannot take place when α-ketoglutarate oxidation is prevented. This is indeed so, since low concentrations (for example, 0·5 μM) of β-chlorovinyl arsenious oxide, which specifically interfere with the dehydrogenation of α-keto-acids, prevent the oxidation of glutamate and *iso*citrate as well as of α-ketoglutarate. Presumably the site of action of the arsenical is the lipoate involved in the dehydrogenation of α-ketoglutarate[6]. β-Chlorovinyl arsenious oxide does not inhibit glutamate dehydrogenase since, on addition of diphosphopyridine nucleotide together with cytochrome c and sufficient of the detergent 'Triton' to cause lysis of the mitochondria, oxidation of glutamate proceeds rapidly in the presence of the arsenical. It would appear that the inhibition of glutamate oxidation observed with intact mitochondria is due to accumulation of α-ketoglutarate, and that with particles treated with detergent glutamate oxidation is not dependent on the subsequent enzymatic removal of the keto-compound.

Krebs and Bellamy[7] have recently demonstrated a mechanism for the utilization of glutamate which involves transamination :

$$\begin{array}{l}\text{oxaloacetate} + \text{glutamate} \rightarrow \text{aspartate} + \\ \qquad\qquad\qquad\qquad\qquad\qquad \alpha\text{-ketoglutarate} \; ; \\ \alpha\text{-ketoglutarate} + 1\tfrac{1}{2}O_2 \rightarrow \text{oxaloacetate} + CO_2 \\ \hline \text{sum} : \; \text{glutamate} + 1\tfrac{1}{2}O_2 \rightarrow \text{aspartate} + CO_2\end{array}$$

In this, the oxidation of glutamate to α-ketoglutarate is at most needed as a priming reaction. It is clear that any mitochondrial oxidation of glutamate by the mechanism of Krebs and Bellamy will likewise be inhibited by β-chlorovinyl arsenious oxide, since the reaction sequence is completely dependent on the oxidation of α-ketoglutarate. In presence of the arsenical, however, glutamate could still undergo oxidation to α-ketoglutarate were it not that this is prevented by accumulation of the product, as already indicated.

With *iso*citrate as substrate a further factor is involved. Oxidation of this substance depends on re-oxidation at the expense of oxaloacetate of the reduced triphosphopyridine nucleotide which is generated by the *iso*citrate dehydrogenase. In the presence of β-chlorovinyl arsenious oxide, the level of oxaloacetate is insufficient, but the further addition of catalytic amounts of malate leads to restoration of *iso*citrate oxidation[8].

Since ADP is required for the oxidation of α-ketoglutarate, glutamate or *iso*citrate, in the presence of DNP, only when oligomycin is also added, it must be inferred that (*a*) in absence of oligomycin, DNP ensures a supply of ADP from the endogenous adenine nucleotide adequate for the needs of the succinyl coenzyme A synthetase (*P*-enzyme), and (*b*) oligomycin reduces the production of ADP until this becomes the limiting factor. Presumably its inhibitory effect on DNP-stimulated mitochondrial adenosine triphosphatase[1] would account for this. The requirement for inorganic phosphate for DNP-stimulated oxidation of glutamate[9], and the similar requirement for *iso*citrate oxidation (unpublished work by J. B. C.), are seen to result from the demands of the *P*-enzyme. It was found that no added phosphate was required for DNP-stimulated oxidation of proline, succinate, malate or β-hydroxybutyrate.

It seems clear, therefore, that oligomycin, which inhibits respiratory-chain phosphorylation[1], does not affect substrate-level phosphorylation. It is interesting to inquire whether this antibiotic inhibits at each of the three possible sites of respiratory-chain phosphorylation. It is possible to isolate single phosphorylation steps corresponding to two of these. Thus (i) with succinate as substrate and ferricyanide as electron acceptor, and (ii) with *p*-phenylenediamine as substrate and oxygen as acceptor, ADP does not stimulate electron transport in presence of oligomycin, although DNP does. Whether oligomycin exerts an inhibitory effect at the remaining phosphorylation site, namely, that adjacent to diphosphopyridine nucleotide, is at present unknown, although it is likely that it does, for the following reason. Oligomycin reduces the ADP-stimulated respiration with DPN-linked substrates to the corresponding state-4 rate (ref. 10), which is lower than the state-4 rate or the rate obtained in presence of ADP together with oligomycin in both cases (i) and (ii) mentioned above.

The decline in respiration in absence of adenine nucleotide (Fig. 1*B*), although due ultimately to failure of oxidation of α-ketoglutarate, is probably accentuated by loss of cofactors or other damage to the integrated mitochondrial respiratory system. Some evidence for this is as follows. If the concentration of the swelling agent, inorganic phosphate, was lowered from 16 m*M* to 2·5 m*M* or less, then, with oligomycin and DNP but no adenine nucleotide, addition of ADP after the respiratory-rate had fallen off re-instated the respiration ; but this did not occur with the higher concentration of phosphate. Furthermore, with some mitochondrial preparations, after swelling had occurred in the presence of DNP, oligomycin and 16 m*M* inorganic phosphate and absence of adenine nucleotide, addition of diphosphopyridine nucleotide and cytochrome *c* restored respiration, whereas with unswollen mitochondria a similar addition did not significantly increase the rate of DNP- or ADP-stimulated respiration.

It remains to be considered why, in presence of oligomycin, glutamate, DNP and a high concentration of phosphate, swelling occurs in the absence but not in the presence of ADP. It emerges from what has been said that in the absence of ADP an accumulation of α-ketoglutarate is to be expected. This would not occur in the absence of oligomycin, or in the presence of oligomycin together with ADP, since under these conditions α-ketoglutarate is oxidized. One is tempted to speculate that swelling in media which pre-dispose to this effect, for example, those containing high concentrations of phosphate, is connected with this accumulation of α-keto-acid.

To summarize, in a salt medium containing 16 m*M* phosphate and of low sucrose content, the respiration of rat-liver mitochondria in the presence of oligomycin and dinitrophenol is not maintained unless ADP is added as well. This phenomenon is observed with α-ketoglutarate, and with glutamate and *iso*citrate which give rise immediately to this keto-acid, but not with other substrates, and is ascribed to the requirement for ADP for substrate-level phosphorylation. Under these conditions the mitochondria swell rapidly in the absence but not in the presence of ADP, and damage to the respiratory system consequent on swelling may be a contributory cause of the decline in respiration.

We thank Miss Freda Johnson for expert technical assistance and Dr. A. S. Mildvan for criticizing the manuscript.

OSMOTIC PRESSURE EFFECT OF THE RED BLOOD CELLS—POSSIBLE PHYSIOLOGICAL SIGNIFICANCE

By Dr. A. TYBJAERG HANSEN

Laboratory of Biophysics, Rockefeller Institute, New York

THE present concept of the net fluid volume transfer across the capillary wall rests mainly on the balance between the hydrostatic and colloid osmotic pressures as expressed in Starling's hypothesis[1]. The osmotic forces demonstrated in the conspicuous and well-known behaviour of the red blood cells as perfect osmometers[2–6] have not been invoked in attempts to explain the obvious inconsistencies between Starling's hypothesis and a series of common clinical observations related to œdema formation.

Osmotic Pressure Effect of the Red Blood Cells

During attempts to measure the colloid osmotic pressure of whole blood it became apparent that the red blood cells could influence the osmotic pressure under certain conditions in an electronic osmometer[7–9]. Fig. 1 shows the results of a single experiment. The first upward deflexion is due to the osmotic pressure generated by plasma when the reference fluid in the osmometer is 0·5 per cent sodium chloride. The very much higher pressure that follows develops when a sample of red blood cells concentrated by centrifugation in the same plasma is placed on the semi-permeable membrane, the reference fluid here also being 0·5 per cent sodium chloride. With plasma the pressure settles at a level of about 33 mm. mercury. When red blood cells form the sample the pressure decreases slowly after a maximum of about 400 mm. mercury has been reached. This is in accordance with the fact that the initial salt concentration difference between the reference fluid and the plasma remaining between the red blood cells is being eliminated by diffusion. The abrupt drop of pressure to the far right is caused by flushing with a 0·5 per cent sodium chloride solution. The effect of the salt concentration difference in the sample of the red blood cells is depending on the permeability of the membrane of the red blood cell, whereas the tiny and rapidly eliminated overshot in the plasma curve is the osmotic effect of the salt concentration difference across the semi-permeable membrane of the osmometer.

In Fig. 2 are shown semi-quantitatively a few principal experiments. The diagram can be interpreted as follows:

When the red blood cells are in close apposition to the semi-permeable membrane of the osmometer (*C*, *D*, *F*, *G*) but otherwise not (*E*), they exert an osmotic effect as if the semi-permeable membrane were replaced by a membrane having the osmotic characteristics of the membrane of the red blood cell. The difference between the osmolar concentration within the red blood cells and that of the reference fluid therefore determines the osmotic flow out of the measuring chamber and the resulting negative sub-atmospheric) equilibrium pressure (*C*, *D*, *F*, *G*). Differences in concentration of substances (as, for example, urea) which penetrate the red cell membrane exert no osmotic effect of their own and do not interfere with that of the salt (*G*). No hæmolysis was observed and hæmoglobin inside the red blood cell was found to be without colloid osmotic effect in the osmometer (*F* 0·9). The plasma protein in the space between the red blood cells exerts its usual colloid osmotic pressure (*B*) across the semi-permeable membrane (the low pressure in all the instances except *A* and *F*). The colloid osmotic pressure itself is not influenced by the various salt concentrations used (*B*). However, by restricting the amount of water available to the red blood cells outside the measuring chamber (*C* 0·5 as compared to *F* 0·5), the protein enhances the osmotic effect of the salt concentration differences.

The maximum osmotic pressure that can be developed by a sample of red blood cells equilibrated with a 0·9 per cent sodium chloride solution (310 milliosmolar) when the reference fluid is a 0·5 per cent sodium chloride solution (162 milliosmolar) is :

$$(310-162)\ 17 = 2{,}516 \text{ mm. mercury}$$

where 17 is the factor used for the conversion of concentration into pressure $\left(\frac{22\cdot4 \times 760}{1{,}000} = 17\right)$, when concentration is expressed in milliosmoles.

A volume transfer from the measuring chamber into the sample creates a negative pressure of 1 mm. mercury per 4×10^{-4} mm.^{3}.

The volume of one single layer of red blood cells on the semi-permeable membrane (area 40 mm.^{3}) is 4×10^{-2} mm.^{3}. The water phase is 0·6.

If all the water (V) is taken up from the measuring chamber we have the following equation at equilibrium pressure, where the subscript to V denotes the number of layers of red blood cells:

$$\frac{V_1}{4 \times 10^{-4}} = 2{,}516 - \frac{V_1 \times 310}{0\cdot6 \times 4 \times 10^{-2}}\ 17 \sim 30 \text{ mm. mercury}$$

Fig. 2. The resilient plate is part of an electric capacitor. Its deflexion is detected by the change in capacitance to which it gives rise. The graduation shown on the pressure chamber of the osmometer is related to the order of magnitude of the actual pressures obtained rather than to exact values. The deflexion of the resilient plate is grossly exaggerated for the sake of distinction. The actual volume displacement is 4×10^{-4} mm.^{3}/mm. mercury

With 500 layers of red blood cells roughly equivalent to the usual samples the equation is:

$$\frac{V_{500}}{4 \times 10^{-4}} = 2{,}516 - \frac{V_{500} \times 310}{0\cdot6 \times 500 \times 4 \times 10^{-2}}\ 17 \sim 2{,}160 \text{ mm. mercury}$$

Considering that some water is available outside the osmometer, and that diffusion, as mentioned, tends to eliminate the original concentration difference, the actual maximum pressure values of 400–1,000 mm. mercury are acceptable as being of the same order of magnitude.

Red Blood Cells in the Capillaries

It has been tacitly accepted that the osmotic conditions in the capillaries are determined solely by the plasma and the capillary wall, leaving no role for the red blood cells, as already mentioned. The validity of this concept is not obvious when it is realized that the red blood cells often pass capillaries in close contact with the wall and tightly squeezed (Fig. 3),

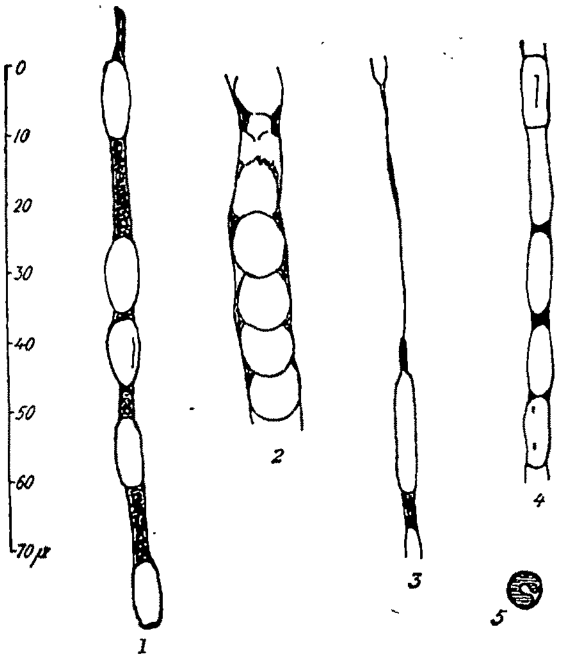

Fig. 3. Muscle capillaries from guinea pig, vitally injected with Indian ink. Walls of capillaries not shown. (From A. Krogh, ref. 25)

and that the capillary wall and the tissue fluid are analogous to the semi-permeable membrane and the reference fluid of the osmometer respectively. In Fig. 4, (*a*) represents the present concept and (*b*) the situation in which the red blood cell may exert an osmotic effect across the capillary membrane. The dilatation of the capillary in case (*a*) is meant as symbolic only. However, the acceptance of the mechanism postulated in (*b*) would require it to be real in order that the same effect be obtained.

As an osmolar concentration difference between the red blood cell and the tissue fluid makes it easier to explain the transfer mechanism, blood is assumed to enter the capillary with a slightly higher salt concentration ($C + \Delta C$) than that existing in the tissue fluid (C). Osmotic equilibrium between plasma and red blood cells prevails at both ends of the capillary. For the sake of simplicity it is further assumed that: (1) the volume of the tissue fluid is equal to the water phase of the blood in the capillary; (2) the colloid osmotic pressure is balanced by the hydrostatic pressure throughout the capillary. In (*a*) any exchange across the capillary membrane is diffusional, and consequently no net volume transfer takes place. The protein is concentrated by a factor :

$$\frac{C + \Delta C}{C + \frac{\Delta C}{2}}$$

which is immaterial as ΔC is small. The volume change of the red cell is accomplished by a redistribution of water entirely within the capillary. In (*b*), however, the water is taken up from the tissue fluid by the red blood cells adjoining the capillary wall, presumably with little interference from this structure, which is known to offer less resistance to water flow than the membrane of the red blood cell itself[10]. In the plasma section of (*b*) diffusion equilibrium obtains as in (*a*). The plasma protein may enhance the effect of the red blood cells as in the osmometer. Its concentration remains unchanged.

Salt concentration differences between plasma and tissue fluid as assumed here are physiologically very probable as a result of resorption and excretion of salt and water. They are inherent in a concept of dynamic equilibrium and will lead to water transfer via the red blood cells in or out of the capillaries dependent on the direction of the concentration difference.

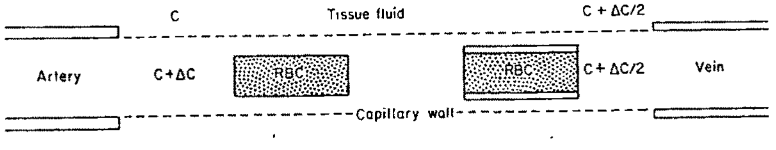
Even less hypothetical is the osmolar concentration gradient between the red blood cells and the tissue fluid that results from the respiratory function. The difference is a consequence of the increase of the osmolar concentration in the red blood cells as they pass along the capillaries releasing oxygen and taking up carbon dioxide. This is observable as a swelling of the red blood cells. Such a swelling of the red blood cells was discovered by Nasse[11] and observed both *in vitro* and *in vivo*, and has been studied among others by Hamburger[12], Warburg[13], Van Slyke[14] and Henderson[15]. Apart from the very minute effect it might have on the protein concentration[16,17] it has not been associated with important physiological functions, although Nasse felt that it was bound to be important. The osmotic effects of the phenomenon have been imitated by means of my technique (Fig. 5), and an estimate of the water transfer capacity is possible.

If Henderson's figures for the increase in volume of the red blood cell are used, we shall have for the resting person with an average arterio-venous oxygen deficit: measured volume increase of red blood cell 1 per cent, water phase 0·6. The total osmolar concentration is about 300 milliosmoles, the increase consequently 4·5 milliosmoles.

The total amount of water taken up by the red blood cells in 24 hr. at rest, assuming a hæmatocrit of 50 per cent and a cardiac output of 5 litres per min., will be:

$$\frac{5 \text{ litres} \times 24 \times 60 \times 50 \times 1}{100 \times 100} = 36 \text{ litres}$$

a) Blood homogeneous



b) Blood inhomogeneous

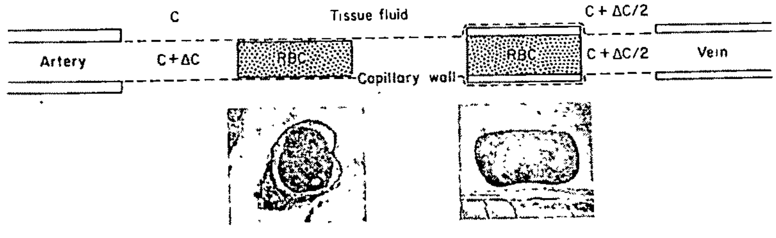


Fig. 4. The inserted photoelectron micrographs are from the heart of a rat. The completely solid appearance of the squeezed red blood cells is noteworthy. (The micrographs were kindly placed at my disposal by Dr. George E. Palade, Rockefeller Institute)

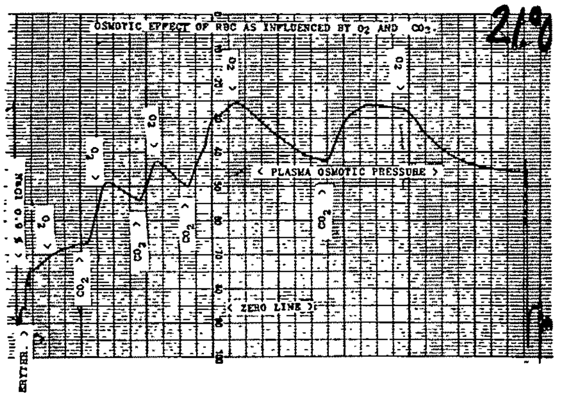

Fig. 5. Variation of the osmotic pressure of red blood cells under influence of carbon dioxide and oxygen. The aeration takes place from the surface of the sample not facing the semi-permeable membrane. This causes the effect to be relatively small and slowly developing

If all the capillaries were dilated as in Fig. 4*a*, all this water would be taken up from the plasma inside the capillary. If they were contracted as in Fig. 4*b* and we assign a length of 7μ and a radius of 1·5μ to the cylindrically deformed blood cell (Fig. 3), 8 litres would be taken up from the plasma across the two end surfaces and 28 litres across the capillary wall. This is still an amount that would seem to be abundant for any demand on water transfer across the capillary membrane, and certainly sufficient to remove the surplus of water formed metabolically in the tissue, which amounts to about 300 ml. per day. The mechanism is particularly suited for this task because the water-removing capacity of the red blood cells is proportionate to the oxygen metabolism, locally as well as totally. It should also be remembered that although the maximum capacity for water transfer seems very high indeed, any intermediate exploitation of the capacity between zero and maximum may be attained depending on the state of dilatation of the capillaries at any time and at any site.

The water taken up by the red blood cells from inside or outside the capillaries is in turn released in the lung capillaries. Any adverse effect of water transfer across the capillary wall into the tissue is prevented by the colloid osmotic pressure of the plasma, which is here in normal cases always in excess of the hydrostatic pressure—the only place in the organism where this is true. A small part, about 350 ml. in 24 hr., is excreted here as water vapour. In the glomeruli there is no deoxygenation of the red blood cells and, therefore, no interference with the filtration.

The red blood cells may take up water against a hydrostatic pressure in excess of the plasma colloid osmotic pressure, provided the wall supports it as the semi-permeable membrane does in the osmometer. The apparent effect would be that of a higher colloid osmotic pressure than the one measured *in vitro*. In the example in which the osmotic concentration rose 4·5 milliosmoles the equivalent pressure would be:

$$17 \times 4 \cdot 5 = 77 \text{ mm. mercury}$$

The suction effect is in addition to that of the colloid osmotic pressure, but the effect diminishes as water is taken up. If, therefore, the plasma section and the red blood cell section are of equal volume, the maximum excess of hydrostatic pressure that the red blood cells will be able to counteract is that which they can exert after they have taken up the water which has left the capillary in the plasma section. In my example it is about:

$$\frac{28}{36} \times \frac{77}{2} \text{ mm. mercury}$$

in excess of the colloid osmotic pressure. This pressure effect could easily be doubled within the physiological limits of deoxygenation.

Discussion

One of the reasons for this attempt to evaluate the hypothetical function of the red blood cells in some detail is its relation to net volume translocation across the capillary wall, which is now not satisfactorily understood[18–20].

In contrast to the exchange of solutes across the capillary wall, which can be accounted for by diffusion[10,21], net volume transfer requires hydrostatic or osmotic forces.

Starling's hypothesis provides for osmotic forces, and physiological experimentation has shown that fluid movement across the capillary wall can be brought about in agreement with the colloid osmotic pressure[1,22–24]. However, strictly speaking, such results only show that the capillary wall by and large is impermeable to proteins and freely penetrable for water and crystalloids, and that the colloid osmotic pressure is about the same as the hydrostatic average pressure in the capillaries. It does not seem permissible to infer that the hypothesis represents the sole mechanism by which net volume transfer between the vascular and the tissue fluid compartments takes place, and clinical observations, as mentioned in the introduction, make it clear that this is not likely.

A mechanism as the one discussed, based on an osmotic effect of electrolytes and closely associated with the capillary function (no matter how this function is conceived[25,26]) as well as with renal, respiratory and metabolic functions, would supplement the present concept of volume translocation in a very helpful way.

By invoking the surplus of suction effect of the red blood cells in contracted capillaries it would be easier to understand that a normal person does not accumulate œdema in the legs in spite of a capillary pressure here much higher than the colloid osmotic pressure[27]. In cardiac failure dilatation of the capillaries[28] as secondary to the well-known increase in vascular volume[29] would reduce the transcapillary osmotic effect of the red blood cells and thus explain why œdema develops, although the capillary pressure is not materially higher than in normal people.

Nephrotic œdema would be the result of an enhanced transcapillary filtration due to the low colloid osmotic pressure but with normal plasma–red blood cell ratio. Anæmic œdema[30] would develop as a result of increased transcapillary filtration due to an enlarged plasma section relative to the red blood cell section but with normal colloid osmotic pressure. In both cases the capacity of the red blood cells to remove water from the tissue fluid would have been exceeded. The final result would be influenced by the state of contraction of the capillaries, and this could be the explanation for the very puzzling fact that nephrotic œdema may be excreted without change of colloid osmotic pressure (ref. 31 and my observations), and, as it must be surmised, with an adverse change of tissue pressure and extracapillary colloid osmotic pressure—the other forces that play a part in Starling's hypothesis.

The cases of severe chronic cor pulmonale with œdema that vanishes with treatment which improves the low arterial oxygenation and the carbonic dioxide retention, but otherwise has no direct effect, may represent an interference with the osmotic function of the red blood cells because of faulty gas exchange.

These are all examples of clinical facts hitherto unexplained. The demonstration of negative tissue pressure, by Guyton *et al.*[32], the fact that the joint cavities are kept 'dry', and Mannery's estimate[33] that the tissue fluid is normally only sufficient to cover the structures with a thin layer of tissue fluid, fit in well with the surplus of suction effect that the red blood cells might be able to generate. An effect would be self-limiting by the increase in surface tension forces in the tissue and the increase in colloid osmotic pressure of the tissue fluid that it would bring about.

Finally, the observation repeatedly made in perfusion experiments, that blood is superior to plasma in preventing œdema[34-36], and that oxygenated blood is better than deoxygenated[37], would seem less controversial[38-40] in the light of a red blood cell effect than it does now.

The argument and the examples presented here are not meant as a substitute for experimental scrutiny, as it is all too obvious that our present knowledge about the capillary circulation is too meagre to permit any solid deductions. It might, however, be worth while to take the suggested possibility into consideration in future work in the many fields where the capillary circulation plays a significant part.

COMPARISON OF AN ATTENUATED AND VIRULENT LOUPING ILL STRAIN

By M. GREŠÍKOVÁ, P. ALBRECHT and E. ERNEK

Institute of Virology, Czechoslovak Academy of Sciences, Bratislava

OUR work on the 'attenuated strain of louping ill virus' began in 1957 [1] during experiments on the transmission of tick-borne encephalitis viruses by milk of domestic animals. Besides the Czechoslovak strain *Hypr* of tick-borne encephalitis a virus strain labelled by the Institute of Epidemiology and Microbiology in Prague as louping ill was included in our investigation so as to compare the properties of both strains. It was found that the strain *Hypr* of tick-borne encephalitis (TBE) when inoculated subcutaneously to sheep caused regular viræmia and excretion of virus into milk in large quantities (Table 1). After intracerebral infection it caused death 5–6 days later. In sheep infected with the louping ill strain, viræmia was of short duration and excretion of the virus by milk was observed only in two out of six animals (Table 2).

Therefore, we decided to investigate more carefully the properties of the aforementioned louping ill strain, which was originally obtained by Dr. Gallia, Institute of Epidemiology and Microbiology, Prague, and passed to our Institute in 1956. Further, we shall call this strain 'attenuated louping ill strain'. For comparison, another louping ill strain was chosen isolated recently from Nature and kindly supplied by Dr. MacCallum, London. This strain was used in its second to fourth intracerebral passage on mice and will be called 'virulent louping ill strain'.

The pathogenicity of the two louping ill strains was examined in white mice from two breeds with higher (Děčín) and lower (Dobrá Voda) susceptibility, in suckling rats, hamsters, monkeys and sheep (Table 3).

The virulent louping ill strain was pathogenic after intracerebral inoculation for all animals listed. After intracerebral infection in sheep, it caused regular encephalitis and death.

The 'attenuated louping ill strain' killed mice both after intracerebral and peripheral inoculations; suckling rats and young hamsters died after intra-

cerebral inoculation. It produced, however, no clinical symptoms or death in monkeys and sheep. Even after massive intracerebral inoculation with a 10 per cent suspension containing $10^{8.52}$ LD_{50}, no signs of illness occurred.

The titres for the two strains are shown in Table 3.

The differences in pathogenicity of the two louping ill strains led us to examine the course of infection in their closest and most susceptible natural host, namely, in sheep.

After infection with the virulent louping ill strain, elevation of temperature ensued 3–4 days later, reaching 41·7° C. On the fifth day tremor, ataxia and paralysis developed. Death occurred 5–7 days after inoculation. On section, a marked hyperæmia and small hæmorrhages were present in the brain and spinal cord. From animals killed at various intervals after inoculation nineteen tissue samples were taken for virological and morphological examinations. After intracerebral inoculation, no virus was present at the 24-hr. interval; 3 days after inoculation it was present only in tissues of the reticulo-endothelial system and in the central nervous system. At the same time, encephalitis could be demonstrated histologically. Five days after inoculation, virus could be demonstrated in high titres (up to 10^6) in brain both virologically and by the fluorescent antibody methods. Inflammatory lesions and damage of neurones were present.

After subcutaneous infection of sheep with the virulent strain of louping ill, a long-lasting viræmia developed, reaching considerable values. In tissues measurable amounts of virus were present not earlier than 3 days after inoculation and again in the lymph nodes and spleen. Five days after inoculation, virus was present in reticulo-endothelial tissues and also in the ganglia of the peripheral nervous system. Slight perivascular changes in the central nervous system 7 days after inoculation pointed to incipient invasion of the central nervous system, although no virus could be demonstrated virologically.

Under similar conditions, experiments were performed with the 'attenuated louping ill strain'. No rise in temperature occurred after intracerebral or subcutaneous inoculation even with a high dose of virus. Attempts to isolate virus from organs of these animals were unsuccessful. Histological examination of animals inoculated intracerebrally showed perivascular infiltrations, although no damage of nerve cells could be demonstrated, as was the case with the virulent strain. No viral antigen could be demonstrated in nerve cells with the method of fluorescent antibodies. Animals inoculated intracerebrally with normal mouse brain or with a suspension of attenuated louping ill virus inactivated at 56° C. for 1 hr., showed no histological changes at all.

To determine whether, in spite of these unusual pathogenic features, the 'attenuated louping ill strain' really belongs to the tick-borne encephalitis group, the neutralizing capacity of sera against different tick-borne encephalitis viruses (Czechoslovak tick-borne encephalitis virus, virulent louping ill and 'attenuated louping ill strains') was tested with the 'attenuated louping ill virus'. The louping ill virus was neutralized in the intraperitoneal neutralization test by all three sera used.

To test the immunogenicity of the two louping ill strains, two sheep were inoculated subcutaneously with the virulent and two with the attenuated strains. Both viruses led to the formation of neutralizing antibodies, the neutralization index reaching values of more than 3 logarithms.

In a protection test, sheep were inoculated with a 10 per cent suspension of the attenuated louping ill strain. Ten and 14 days later, they were challenged with the virulent louping ill strain. Control animals which received only the virulent strain died 7 days after inoculation. Sheep inoculated first with the attenuated strain, remained well for the following 14 days of observation.

Preliminary results only have been reported here. Perhaps these findings could form a basis for a possible use of this strain for the preparation of a vaccine against viruses of the tick-borne encephalitis complex.

TWO PHOTOCHEMICAL SYSTEMS IN PHOTOSYNTHESIS

By Dr. L. N. M. DUYSENS, J. AMESZ and B. M. KAMP

Biophysical Laboratory of the State University, Nieuwsteeg 18, Leyden, Netherlands

BY sensitive differential absorption spectroscopy it was demonstrated[1] that illumination causes oxidation of an *f*- or *c*-like cytochrome in *Porphyridium cruentum*. The action spectrum for cytochrome oxidation showed a maximum at 680 mμ, apparently due to chlorophyll *a*, and a much lower maximum at 560 mμ, probably due to phycoerythrin[2]. This was surprising, since light of 680 mμ is known to be far less efficient in bringing about photosynthesis and chlorophyll *a* fluorescence than equally intense light of 560 mμ (ref. 3, cf. ref. 4). From this, it followed that at least two photochemical pigment systems are present in *Porphyridium*. The system which is mainly responsible for the action spectrum of chlorophyll *a* fluorescence is called system 2. System 2 contains fluorescent chlorophyll *a* and a high proportion of phycobilins, mainly phycoerythrin; light quanta absorbed by phycoerythrin in this system are transferred to the fluorescent chlorophyll *a* and are thus photochemically active (cf. ref. 3). The other system, 1, contains non- or weakly fluorescent chlorophyll *a* and less phycobilins, and is active in cytochrome oxidation. We will assume that only these two pigment systems are present in *Porphyridium*; this assumption will prove sufficient for a satisfactory interpretation of our experiments.

It has also been observed[2] that the kinetics of cytochrome oxidation were different in light of 560 mμ from those in light of 680 mμ. This phenomenon shows that at least two pigment systems, which according to the preceding assumption must be the systems 1 and 2, interact in the cytochrome reaction. The kind of interaction is shown in Fig. 1. The decrease in absorption at its maximum, 420 mμ, which was shown to be a measure of the oxidation of the cytochrome, was recorded. The recorder tracing shows that actinic light of 680 mμ causes oxidation of the cytochrome; additional illumination with actinic light of 560 mμ causes a reduction of this cytochrome. Addition of the herbicide 3-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU) to the very low concentration of $1 \cdot 1 \times 10^{-6}$ *M* inhibited the reduction at 560 mμ; an oxidation is observed instead. A similar effect was observed in the presence of $4 \cdot 3 \times 10^{-2}$ *M* N-ethylurethane. The simplest interpretation of these experiments is that system 1, with a predominant activity at 680 mμ, directly or indirectly oxidizes, and that system 2, with predominant activity at 560 mμ, reduces the cytochrome; DCMU prevents system 2 in some way from reducing the cytochrome.

The action spectrum of cytochrome oxidation in the presence of DCMU or N-ethylurethane is shown in Fig. 2. According to the previous interpretation, this action spectrum should be equal to that of system 1.

It was found that the action spectrum of systems 1 and 2 varied for different cultures. We estimated the ratio of activities at 560 and 680 mμ to vary for system 2 between at least 2·4 and 6, and the corresponding ratio for system 1 from 0·8 to 1·2. The ratio for system 2 was calculated from earlier measurements[3a,4].

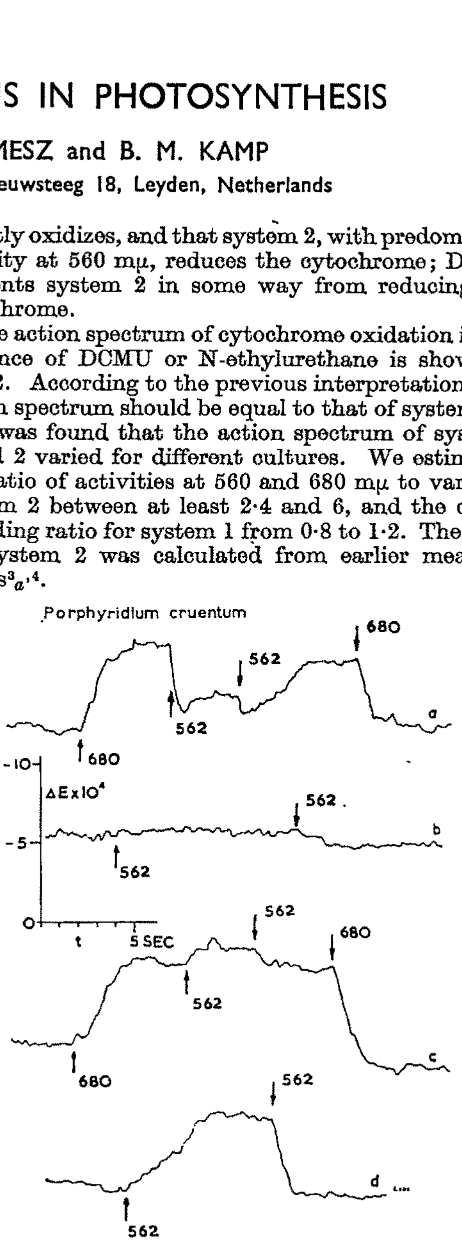

Fig. 1. Recorder tracings of absorption changes of *Porphyridium cruentum* at 420 mμ in the absence (*a*, *b*) and in the presence (*c*, *d*) of DCMU. Upward deflexions are decreases in absorption and reflect the oxidation of cytochrome. Upward and downward pointing arrows indicate the switching on and off of the actinic light. (The intensities are $4 \cdot 4 \times 10^{-10}$ Einstein/(cm.^{2} sec.) at 680 mμ and $5 \cdot 3 \times 10^{-10}$ Einstein/(cm.^{2} sec.) at 562 mμ.) Tracing (*a*) shows a reduction of the cytochrome by light of 562 mμ

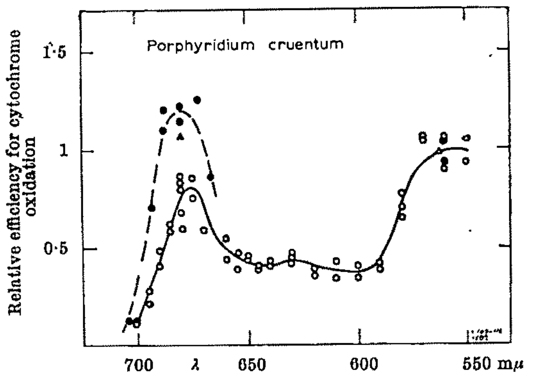

Fig. 2. Action spectrum for cytochrome oxidation in the presence of N-ethylurethane (open circles) and of DCMU (solid circles and triangles) for three different cultures of *Porphyridium cruentum*

Because of the approximate proportionality between the action spectrum of photosynthesis and that for excitation of chlorophyll *a* fluorescence, it had been concluded[3,5] that the pigment system responsible for the chlorophyll *a* fluorescence (system 2) was active in photosynthesis. The non- or weakly fluorescent chlorophyll *a* was believed to be inactive. However, the fact that both systems react with the same cytochrome indicates that system 1 also participates in photosynthesis and supplements in some way system 2. The relatively good quantum efficiency for cytochrome oxidation (about 5 quanta absorbed at 680 mμ per cytochrome molecule oxidized[2]) supports this view.

Further support for the hypothesis that systems 1 and 2 interact in photosynthesis was obtained from photosynthesis measurements by means of an oxygen polarograph, similar to one described recently[6]. The relative rates of photosynthesis calculated per equal number of incident quanta per sec., for light of 570 mμ and 680 mμ, were 83·5 and 20·6 (ratio, 4·0) and, with $2{\cdot}1 \times 10^{-3}$ *M* N-ethylurethane, for another sample of the same culture, 59·5 and 9·6 (ratio, 6·2). It is interesting to see that the percentage inhibition, which at a given wave-length is the same for various intensities, is smaller in actinic light of 570 mμ than in that of 680 mμ. This phenomenon was observed with both DCMU and N-ethylurethane with four different cultures. An experiment with DCMU gave a ratio 560/680 mμ of 7·0, as compared with a ratio of 4·4 without inhibitor.

When photosynthesis of unpoisoned *Porphyridium* was measured at 680 mμ with a background of strong light of 562 mμ, the rate of photosynthesis was found to be enhanced considerably (by a factor of 2). A similar enhancement effect has been observed for species of algae of different groups by Emerson and co-workers[7], and more recently by other authors, and has been called the 'Emerson effect'. The enhancement effect earlier observed[8,9] in *Porphyridium* occurred to a smaller extent and under conditions different from those reported here.

Our experiments can be interpreted as follows: In order to bring about photosynthesis, systems 1 and 2 must both be excited. If system 2 is strongly inhibited, the rate of photosynthesis, and thus the action spectrum of photosynthesis, will be mainly determined by system 2 at all wave-lengths. In uninhibited algae, however, system 2 is more active than system 1 at 560 mμ, and less active at 680 mμ. If the algae are illuminated with both wave-lengths simultaneously, then the rate of photosynthesis will be higher than the sum of the rates at each wave-length separately, because by simultaneous illumination the excess absorptions supplement each other.

The 'Emerson effect' has been observed for a variety of algae, belonging to different classes. This indicates that the scheme of Fig. 3, which summarizes and generalizes our hypothesis, applies also for other algae and probably for higher plants too.

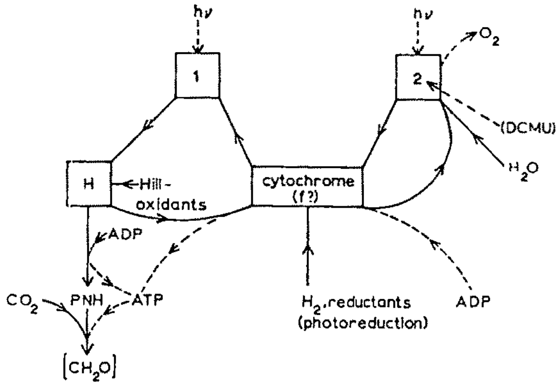

Fig. 3. Hypothetical scheme showing functions of systems 1 and 2 in photosynthesis

Further evidence for this scheme is as follows. DCMU, which strongly inhibits photosynthesis, does not inhibit the photoreduction of carbon dioxide with hydrogen gas in *Scenedesmus*[10] and the photoreduction of triphosphopyridine nucleotide (TPN) by spinach chloroplasts in the presence of ascorbic acid and a catalytic amount of 2,6-dichlorophenol indophenol[11]. This indicates that these photoreductions proceed via system 1 solely. The action spectrum for the reduction of phosphopyridine nucleotide (PN) in the blue alga *Anacystis nidulans* in the presence of DCMU was found to be proportional to the action spectrum for cytochrome oxidation, also measured in the presence of DCMU[12]. Thus reduction of PN is presumably closely linked to system 1.

The observation[13] that also the Hill reaction of *Chlorella* with quinone shows an 'Emerson effect', indicates that both systems 1 and 2 participate in the Hill reaction.

Our scheme is intended as a working hypothesis, which is certainly incomplete, and may require modification. At present it explains most experiments known to us in a simple and plausible way. A more detailed report is in preparation, in which we will discuss partly similar but less detailed and experimentally less supported hypotheses concerning the role of the photosynthetic pigments which have been proposed recently by other authors.

This investigation has been aided by financial support of the Netherlands Organization for the Advancement of Pure Research (Z.W.O.).

WOOD-BORING ACTIVITY OF *LIMNORIA* (ISOPODA) IN RELATION TO OXYGEN TENSION

By Dr. S. K. ELTRINGHAM
The Wildfowl Trust, Slimbridge, Gloucestershire

CONFLICTING reports are found in the literature concerning the effect of pollution on the wood-boring activity of the marine isopod *Limnoria*. Some authors[1–3] consider it has a deleterious effect, others[4–7] that it has no effect, while Fraser[8] maintains that a moderate degree of pollution is beneficial to the borer. The confusion probably arises from the various forms the pollution can take, for example, chemical, oil or organic. The toxicity of chemical effluents will depend on their concentrations; but it was thought that organic pollution affected *Limnoria* to the degree by which it reduced the dissolved oxygen content through its decomposition. It was observed that *Limnoria* abandon their burrows in stagnant sea-water, and this reaction has been made the basis of an experiment to evaluate the effect of the oxygen tension on the boring activity. The possibility was also considered that changes in *p*H of the water, caused by the decomposition of organic matter on the wood, were responsible for the evacuation of the burrows.

The experimental procedure was as follows: a large piece of piling, showing about 260 sq. cm. of *Limnoria*-attacked surface, was scraped down to remove debris and attached organisms and rinsed several times in clean sea-water. The water-logged wood was immersed in sea-water which had previously been well aerated, and was allowed to stand for a period of five days. Initial measurements were made of the *p*H and oxygen tension of a sample of water taken from near the timber surface. These readings were repeated at intervals during the experiment. Immediately after each set of readings, the wood was taken from the water and all *Limnoria* on the surface were counted and removed. At the end of the experiment the wood was split open and all animals remaining in the wood were counted. Thus the original total population was known, and the percentage of animals leaving the wood at intervals was calculated. A correlation was then sought between these figures and the *p*H and oxygen tension records.

The oxygen tensions were measured by the Whitney syringe pipette method[9], which allowed a sample of water to be taken under the surface adjacent to the burrow entrances. Accurate measurements could not be made below an oxygen content of 0·5 per cent saturation. The readings are given as percentages of the oxygen present in saturated sea-water corrected for temperature and salinity, using the solubility tables of Truesdale *et al.*[10]. The *p*H values were estimated colorimetrically, using a B.D.H. small comparator with phenol red indicator. The salinity of the water was 35·8 per mille and its temperature during the experiment varied between 16° and 17° C.

The timber, which was taken from pine piling at Calshot Pier in Southampton Water, contained three species of *Limnoria*, namely, *L. lignorum* (Rathké), *L. quadripunctata* Holthuis and *L. tripunctata* Menzies. In order that any differences in behaviour could be assessed, the specific composition of a sample of 50 individuals was noted each time a group of *Limnoria* was removed from the wood.

The results of the experiment are given in Table 1. The rate at which *Limnoria* left the wood is compared with the *p*H and oxygen tension readings in Fig. 1. This shows that the desertion of the timber by *Limnoria* was accompanied by a progressive reduction in the oxygen content of the water. There was little variation in the *p*H (8·0–7·6) over the course of the experiment and this small change can have had little effect as *Limnoria* is said[11] to be tolerant of a *p*H range between 4·5 and 9·6. It is a reasonable assumption, therefore, that the exodus of the *Limnoria* was caused by the fall in oxygen tension. From these results an estimate can be made of the percentage saturation value which limits the boring activity.

The plots of the percentage of *Limnoria* leaving the wood fall on a sigmoid curve, the steep slope of which corresponds approximately to the time interval between 25 and 85 hr. During this period of maximum desertion, the oxygen tension fell from

Table 1. RATE AT WHICH *Limnoria* LEFT THE TIMBER UNDER REDUCED OXYGEN CONDITIONS

about 17 to 1 per cent. Below about 17 per cent saturation, therefore, the amount of dissolved oxygen must have begun to exert a limiting effect on the boring activity. The actual values for the water within the burrows were probably somewhat less than those given above. These results show a considerable toleration of low oxygen conditions, for 50 per cent of the *Limnoria* had not left the wood at oxygen tensions as low as 3 or 4 per cent saturation, and even at the end of the experiment, when the oxygen content was too low to be measured, 10 per cent of the *Limnoria* still remained in the wood. There is no certainty, however, that these animals were still able to bore. It is difficult to assess a limiting value for the oxygen tension but it seems probable, from Fig. 1, that the critical value had been reached at 2 per cent saturation.

The figures for the separate species, derived from the analyses of samples each of 50 *Limnoria*, show a difference between *L. quadripunctata* and *L. tripunctata*. A higher proportion of the former species left their burrows earlier, and therefore at a higher oxygen tension, than was the case with *L. tripunctata*. However, the final percentage of either species remaining in the wood at the end of the experiment was the same. The more erratic rate of emergence of *L. lignorum* from the burrows may be an artefact, due to the small numbers of this species present in the total population. However, its behaviour resembled that of *L. tripunctata* in that the majority of the specimens did not leave the wood until very low oxygen conditions (less than 3 per cent saturation) obtained. It seems, therefore, that *L. quadripunctata* is more sensitive than the other species to low oxygen concentrations.

The conclusions of this experiment in relation to pollution apply to those cases in which the pollution causes a reduction in the oxygen tension of the water. It is suggested that if the oxygen dissolved in the water at the surface of submerged timber falls to a level below 2 per cent saturation, the boring activity of *Limnoria* within the wood will cease. This conclusion could have practical applications in problems of *Limnoria* infestations.

I am grateful to Prof. J. E. G. Raymont of the University of Southampton for facilities in the Department of Zoology. The work was carried out during the tenure of a Department of Scientific and Industrial Research maintenance grant.

THE EFFECT OF DEPTH OF TRANSPLANTING ON TILLERING AND SEED PRODUCTION IN WHEAT

By DR. R. HALWAGY

Faculty of Science, University of Khartoum, Sudan, and Faculty of Science, University of Alexandria, Moharram Bey, Alexandria, Egypt

SEVERAL strand plants, namely members of the Gramineae, are known to thrive on wind-blown sand. These are *Agropyron junceum* L., *Elymus arenarius* L. and especially *Ammophila arenaria* Link. The latter species reacts favourably to periodical burial under fresh layers of sand by producing tall robust shoots from the lower leaf axils[1].

Pot experiments with transplanted *Ammophila* culms showed that increased depth of planting tended to produce more stout shoots, although the over-all yield was not greatly affected (Halwagy, unpublished work).

The present work aimed at exploring the possibility of a similar response in a cultivated member of the Gramineae. Wheat (*Triticum vulgare*) was chosen as the study material.

Culms of *Triticum vulgare* (Giza 139) were obtained from the University of Alexandria farm on February 23, 1957. They had been grown from seed on November 17, 1956. The culms were cut back to a uniform length of 50 cm. Of this, 8–10 cm. had been underground, consisting of a few internodes and carrying buds at the nodes. Culms were well mixed before being transplanted in 30-cm. pots, in clayey loam. Each pot had 25 culms; culms and pots being allotted to treatments at random. The pots were arranged in a Latin square of 5 replicates and 5 treatments. The 5 treatments were: culms transplanted at a

Table 1

Treatment	Total No. of shoots	No. of flowering shoots	Dry weight of shoots (gm.)	Dry weight of spikes (gm.)	Dry weight of crop (shoots + spikes) (gm.)
A (transplanted 10 cm. deep)	76 ± 10·02	15 ± 7.64	97·4 ± 26·52	25·59 ± 16·71	123·0 ± 40·74
B (transplanted 15 cm. deep)	92 ± 10·02	52 ± 7·64	185·6 ± 26·52	86·58 ± 16·71	272·2 ± 40·74
C (transplanted 20 cm. deep)	48 ± 10·02	12 ± 7·64	58·7 ± 26·52	19·03 ± 16·71	77·7 ± 40·74
D (transplanted 25 cm. deep)	11 ± 10·02	5 ± 7·64	13·3 ± 26·52	5·48 ± 16·71	18·7 ± 40·74
E (transplanted 28 cm. deep)	16 ± 10·02	10 ± 7·64	16·6 ± 26·52	7·39 ± 16·71	23·9 ± 40·74

depth of 10, 15, 20, 25 and 28 cm. below the soil surface.

On May 13, 1957, the height of all new shoots was measured. On July 4, 1957, the crop was harvested by clipping at soil-level. The following quantitative estimates were made: the total number of shoots, the number of flowering shoots, dry weight of shoots (oven-dried at 105° C.), dry weight of spikes (excluding the spike-bearing stalks, oven-dried at 105° C.) and the mean shoot weight. The results were analysed statistically and the 5 per cent level of significance adopted.

The effect of the depth of transplanting on the yield, as measured by different characteristics, is shown in Fig. 1. The analysis of variance (Table 1) showed that transplanting at a depth of 15 cm. produced a larger number of shoots than all other treatments, transplanting 10 cm. deep excepted. Further, that the number of flowering shoots, dry weight of shoots, spikes and total weight of crop were significantly greater in culms transplanted 15 cm. deep than in any other treatment. The better growth is due to the production of more shoots, vegetative and flowering, rather than producing heavier individual shoots.

The reaction of transplanted wheat culms to various depths of planting, as revealed by this work, is at variance with that of *Ammophila*. For wheat, the optimum depth appears to be 15 cm. In *Ammophila*, the quality rather than the quantity of new growth was influenced by the depth of transplanting. Increased depth (between 10 and 25 cm.) caused a slight increase in the over-all weight of shoots, but had a more pronounced effect on the mean shoot weight. Culms planted at greater depths produced fewer but taller and stouter shoots.

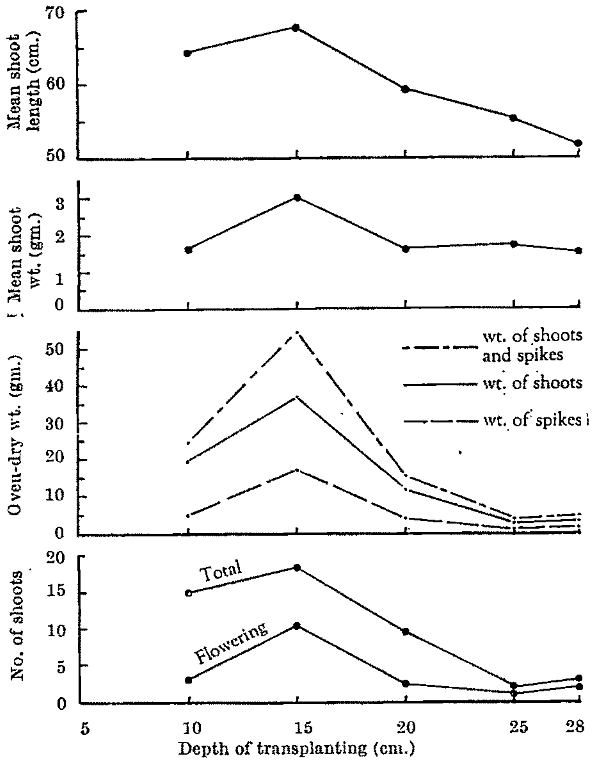

Fig. 1. Effect of depth of transplanting on yield of wheat culms

The nature of the stimulus is not fully understood. It seems likely that by increasing the depth of burial of wheat culms from 10 to 15 cm. the buds are pushed a few centimetres in the soil, where the temperature is more or less constant and large fluctuations in temperature are thus avoided. Moreover, deeper buds become less subject to desiccation when the top centimetres of the soil dry out. These buds will therefore have a better chance of tillering, than the more shallowly placed ones nearer the soil surface.

It is not clear, however, why further burial (at 20, 25 and 28 cm.) does not induce still better tillering. It should be recalled that the yield data are based on the aerial portion of the crop, so that the number and weight of shoots recorded refer to those shoots which emerged above the soil surface. It might have been desirable to investigate the possibility of production, from the deeply buried buds, of tillers which failed to appear above the soil surface and were therefore not taken into consideration.

The results of this experiment are more suggestive than conclusive, and may well prove rewarding if further work is carried out along similar lines. Also, the economic implications of the problem have not been considered. It should be noted that in the field, the usual depth of the underground part of the culm is 8–10 cm. It has been shown that better vegetative growth and seed production may be induced by burying the culms to a depth of 15 cm. Before the advantages of these results are utilized, it is necessary to find out the effect of the mere pulling out and transplanting of wheat culms. Comparison must be made in the field, between the yield of plots on which wheat culms have been pulled and later transplanted 15 cm. deep, and control plots. It is very probable that pulling has an adverse effect on the subsequent growth and seeding of wheat culms, so that any gain in yield obtained through transplanting at a depth of 15 cm. will be counterbalanced by this inimical effect and the additional cost of labour.

Deep burial of seed at the time of sowing may seem an easier and more practicable alternative. But the limitations of this method are obvious since seedlings produced from seeds which had been sown too deeply will fail to emerge above the soil surface.

I am indebted to Prof. A. H. Nasr for various working facilities during the course of this work and to Prof. A. el Khishin for providing wheat culms. Thanks are also due to Dr. S. Tolba and Dr. S. Nasr for statistical advice.

SEX AND STRAIN DIFFERENCES IN ELECTROSHOCK CONVULSIONS OF THE RAT

By D. E. WOOLLEY*, P. S. TIMIRAS, M. R. ROSENZWEIG, D. KRECH
and E. L. BENNETT

Departments of Physiology and Psychology and Lawrence Radiation Laboratory,
University of California, Berkeley

OUR objectives were to determine whether differences in the threshold and pattern of electroshock seizures exist between male and female, and maze-bright and maze-dull rats.

Our interest in this problem developed from the following considerations: (1) Woolley and Timiras[1] have shown that the administration of various sex steroids to rats alters brain excitability as assessed by the electroshock seizure threshold test. The striking excitatory action of œstradiol suggested that female rats might have a lower convulsive threshold than males. (2) Rosenzweig *et al.*[2] have demonstrated that in rats selectively bred for differences in maze-learning ability, the superior learners (S_1 strain) have a higher brain acetylcholine (ACh) content and cholinesterase (ChE) activity than the inferior learners (S_3 strain). They have proposed that the level of central ACh–ChE activity is related to efficiency of neural transmission and of learning. This, together with reports[3] that drugs which lower the convulsive threshold also increase ChE activity in some parts of the cat brain, and with the finding[4] that subconvulsive doses of central excitatory drugs increase the learning ability of the rat, suggested that the S_1 strain might have lower convulsive thresholds than the S_3 strain.

In the present work male and female S_1 and S_3 rats, 125 days of age, were used. Electroshock seizures were produced with the apparatus described in ref. 5; this apparatus has a constant current circuit and can be pre-set to give the desired value of current independently of the resistance of the animal. The electroshock seizure threshold (EST) is defined as the minimal amount of alternating current in milliamperes delivered through corneal electrodes for 0·2 sec. which will elicit a barely detectable clonic convulsion of the ears, jaws and forepaws without loss of equilibrium. A lower threshold is assumed to indicate greater brain excitability.

In Table 1 are shown the EST values for the four sub-groups. In both strains, female rats have a significantly lower value than males. For both sexes, the S_1 rats have a lower EST than the S_3. (The P-values in the table are based on t-tests.) These sex and strain differences are what we expected.

Table 1. ELECTROSHOCK SEIZURE THRESHOLD DIFFERENCES IN MALE AND FEMALE MAZE-BRIGHT AND MAZE-DULL RATS

Strain of Rats*	$\bar{x}$ and σ of electroshock seizure thresholds (m.amp.)		Male vs. female P
	Male	Female	
Maze-bright (S_1)	23·41 ± 0·23	21·15 ± 0·20	< 0·01
Maze-dull (S_3)	24·32 ± 0·33	22·02 ± 0·27	< 0·01
S_1 vs. S_3 P	< 0·05	< 0·02	

* Eighteen rats were used in each of the four sub-groups, for a total of 72; all were about 125 days old.

Because the females were lighter than the males, it was desirable to determine whether EST was related to body weight. Therefore, correlations between body weight and EST were determined for each sex-strain sub-group separately and were then combined by Snedecor's method to give an average correlation. The following product–moment correlation coefficients were found: S_1 ♂, 0·76; S_1 ♀, 0·15; S_3 ♂, 0·51; S_3 ♀, 0·46; average 0·47 ($P < 0·01$). These positive correlations might be explained by either or both of two hypotheses: (1) variations in EST are consequences of the influence of body mass on current spread, and thus on current density in the brain. Therefore, the heavier the animal the greater the current that must be applied to elicit a seizure; (2) body weight and EST are independent expressions of the hormonal and metabolic balance of the animal.

To obtain further information on the effects of tissue mass on current density in the brain, we examined the correlation between brain weight and EST for the various sub-groups. These correlations ranged from − 0·12 to 0·01, none being significantly greater than zero. This may be interpreted as inconsistent with the 'tissue mass' hypothesis. Also, contrary to this hypothesis, is the fact that, although the S_1 and S_3 strains of rats differed significantly in EST, their body weights were equal.

It is known that œstradiol decreases body weight and EST. In support of the 'metabolic' hypothesis is the finding[6] that œstradiol can lower EST before body weight is decreased.

Although we tend to interpret the covariance of body weight and EST as reflecting two relatively independent effects of the hormonal state of the animal, we cannot eliminate completely the 'tissue mass' hypothesis. However, in our second test of brain activity, the maximal electroshock seizure (MES) pattern, the response to the supramaximal stimulus, is independent of current density, as demonstrated in ref. 7.

A maximal electroshock seizure consists of both tonic and clonic components, and in the rat the tonic phase is divided into tonic flexion followed by tonic extension of the limbs. The tonic extensor phase represents the maximal seizure activity of which the nervous system is capable, and its duration is taken as a measure of the spread or reverberation of impulses involved in convulsions. The duration of tonic flexion is proportional to the intensity of the inhibitory state which must be overcome before appearance of the tonic extension. Thus, the longer the tonic extension and/or the shorter the tonic flexion the greater the convulsability.

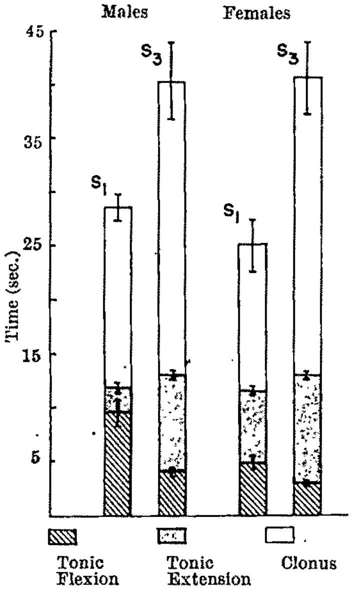

Fig. 1. Maximal electroshock seizure (MES) patterns in male and female maze-bright (S_1) and maze-dull (S_3) rats following a shock of 150 m.amp. for 0·2 sec. Eighteen rats were used in each of the four sub-groups, for a total of 72 rats; all were about 125 days old. Vertical bracketed lines show standard errors of the means for durations of each phase

The MES patterns for the different groups are given in Fig. 1. Again strain and sex differences were observed. 72 per cent of the S_1 males and 8 per cent of the S_1 females failed to exhibit tonic extension, whereas all the S_3 rats showed this phase. Both S_1 males and females showed significantly shorter total tonic and tonic extensor phases and significantly longer tonic flexor phase than the S_3. Duration of clonus was shorter in the S_1 strain than in the S_3.

Thus the maze-bright animals have a seizure pattern which suggests a lesser reverberation of impulses in the brain as compared with the maze-dull, although excitation occurs more readily in the maze-bright. This interpretation is in accord with conclusions[4] derived from investigations of behaviour of the S_1 and S_3 strains.

In both strains the males have a significantly shorter extension and longer flexion than the females. This sex difference can be ascribed to œstradiol, which has been shown[1] to lengthen tonic extension and shorten tonic flexion. Both the longer tonic extensor phase and the lower EST of the females support the view that they have a greater convulsability than males.

In conclusion, it seems to us that female rats have a greater convulsability than males, and both male and female rats of a maze-bright strain have lower seizure thresholds and shorter extensor phases during maximal seizures than maze-dull rats. It is suggested that these sex and strain differences are due to differences in hormonal balance (sex steroids) and brain chemistry (acetylcholine–cholinesterase levels).

EFFECT OF *STAPHYLOCOCCI* ON LEUCOCYTE PYRIDINE NUCLEOTIDES

By DR. M. N. SWARTZ, P. H. BLACK and J. MERSELIS

Departments of Medicine, Harvard Medical School and Massachusetts General Hospital
(Infectious Disease Unit), Boston, Massachusetts

THE presence of a normally inactive diphosphopyridine nucleotide (DPN) pyrophosphatase in *Staphylococcus aureus* has been shown[1] recently. The presence of this enzyme can be demonstrated in whole organisms or in sonic extracts only after certain manipulations such as heat treatment. Because in some circumstances *Staphylococci* may survive in leucocytes after phagocytosis[2], the possibility was entertained that intraleucocytic activation of this staphylococcal enzyme might decrease the pyridine nucleotide-level of the white cell sufficiently to interfere with its metabolism and with its eventual killing of the engulfed micro-organisms.

Changes in glycolysis, and in the monophosphate shunt, as well as in the electron transport system (all involving some pyridine nucleotide-linked reactions) have been reported as occurring in association with phagocytosis. Specifically, studies employing inert polystyrene particles as the foreign material have shown, during the phagocytic event, rather striking metabolic changes, such as increased oxygen uptake, increased lactate production, and increased activity of the monophosphate shunt as evidenced by an increased appearance of C-1 of glucose as carbon dioxide relative to C-6 of glucose[3]. The importance of glycolysis in the successful phagocytosis of heat-killed yeast cells by guinea pig polymorphonuclear leucocytes was further shown in the work of Fisher and Ginsberg[4]. They demonstrated reduced phagocytosis by polymorphonuclear leucocytes which had previously been allowed to react with influenza virus. However, their evidence suggested that the influenza-induced block in metabolism that resulted in decreased phagocytosis was probably at the glucose-6-phosphate to fructose-6-phosphate step.

Studies of oxygen uptake by leucocytes that had phagocytosed heat-killed *Staphylococci* have shown an increased uptake with a coagulase-negative strain of *Staphylococcus epidermidis* and decreased uptake by a coagulase-positive strain of *Staphylococcus*[5]. Similar investigations with viable coagulase-positive *Staphylococci* by the same workers have shown increased uptake of oxygen with one strain and decreased uptake with a second strain. This work, particularly the decreased uptake of oxygen by white cells which had phagocytosed heat-killed coagulase-positive *Staphylococci*, suggested the possibility that the 'heat-activated' DPN pyrophosphatase of the micro-organism might have been active within the leucocyte, since DPN has a well-established role in electron transport. To study possible evidence for activation within the white cell of the normally inhibited DPN pyrophosphatase of *Staphylococcus aureus*, direct measurements of leucocytic pyridine nucleotides following interaction with various types of bacteria were undertaken.

In the work to be described, the polymorphonuclear leucocytes were prepared from exudates produced by the intraperitoneal injection of a sterile 12 per cent solution of neutralized sodium caseinate. The method of collection with heparinized saline, centrifugation, and washing was essentially that described by Sbarra and Karnovsky[5]. Cells were suspended in a Krebs-Ringer phosphate medium buffered at *p*H 7·4. Cells were enumerated in an improved Neubauer chamber, and there was regularly less than 1 per cent contamination with red blood cells. About 85 per cent of the white blood cells were polymorphonuclear leucocytes. The bacteria used were 16-hr. cultures grown with aeration in 2 per cent trypticase broth, except the *Streptococci*, which were grown under relatively anaerobic conditions in the medium of Bernheimer[6]. The number of viable organisms was established by colony counts. The bacteria were then centrifuged and washed twice in 0·9 per cent potassium chloride. Afterwards, they were thoroughly dispersed and suspended in either 0·9 per cent potassium chloride solution or in Krebs-Ringer phosphate buffer adjusted to *p*H 7·4. Incubation mixtures consisted of approximately 4 × 10^8 white blood cells, fresh guinea pig serum in a final concentration of 20 per cent, glucose (28 μmoles), and *Staphylococci* at average multiplicities of 2, 5, 10, 25, or 50 per white blood cell, all in a final volume of 6 ml. The mixtures, in polyethylene tubes, were shaken at 90 cycles/min. in 37° C. water-bath. In later experiments, incubation mixtures of 3 ml. volumes in small silicone-treated Erlenmeyer flasks were shaken under the same conditions. All experiments were carried out aerobically for 40 min. At the conclusion of the experiment the contents of the flasks were chilled, transferred to polyethylene tubes, and centrifuged in the cold at 11,000 *g*. The sedimented cells were then extracted with 5 per cent trichloroacetic acid and analysed for DPN by the methyl ethyl ketone fluorescence method[7]. For the estimation of the reduced form of DPN and TPN, hot 0·1 *N* sodium carbonate extracts were prepared[7].

The DPN content of freshly isolated guinea pig leucocytes was found to be 7·82 ± 0·38 μgm./10^8 white cells (20 determinations). The value for total pyridine nucleotides, that is, including the oxidized and reduced forms of both TPN and DPN, was 14·56 μgm./10^8 white cells. A somewhat lower value (9·22 μgm./10^8 white blood cells) for total pyridine nucleotides of human leucocytes has previously been reported[8].

Within three minutes of interaction with an average multiplicity of fifty viable *Staphylococci* (var. *aureus*, strain No. 241) per leucocyte, the white cell DPN-level began to decrease and continued to decrease over the first 15 min. of incubation (Fig. 1). After this time, for as long as 1 hr. the levels remained stationary. At this same average multiplicity even more striking decreases in the leucocyte DPN-level were produced when older cultures of *Staphylococci* were used. As can be seen in Fig. 2, cells well along in the stationary phase of growth (14–36 hr.) were more effective in lowering the DPN-levels than cells collected in the logarithmic phase of growth. That this enhancement of loss of DPN was not due to an increase in activity of the 'heat-activated' DPN pyrophosphatase of the organism can also be seen in Fig. 2. There was no significant variation in the specific activity of sonic extracts of *Staphylococcus aureus* No. 241 in cells harvested between ten and thirty-six hours of growth. Similar decreases in leucocyte DPNH and TPNH were observed in comparable experiments. The normal level of TPN in the cells was so low as to make measurements of change in its level subject to question.

In order to ascertain whether the decrease of DPN in the white cells was due to intracellular destruction or 'leakage' from the white cells, attempts were made to determine if DPN could be recovered from the medium after 40 min. of interaction of *Staphylococci* with leucocytes. None was recovered following lyophilization of the medium under conditions in which 5 μgm. of added DPN could readily be detected. However, inasmuch as intact guinea pig leucocytes have a potent DPNase which rapidly cleaves exogenous DPN, this experiment has not ruled out the possibility of DPN leakage and subsequent cleavage.

To evaluate further any possible role of the 'heat-activated' DPN pyrophosphatase of *Staphylococcus aureus* in the decrease in pyridine nucleotides of white blood cells, experiments were carried out with boiled *Staphylococci* (pyrophosphatase fully activated) at an average multiplicity of 50 per leucocyte. The decrease with boiled *Staphylococci* proved to be only about 60 per cent of that obtained with unboiled organisms. Although the original

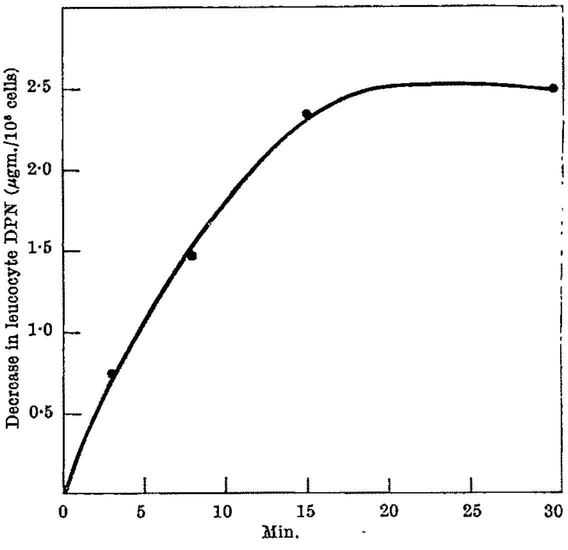

Fig. 1. Time-course of loss of DPN in white cells exposed to *Staphylococcus aureus* strain No. 241, at an average multiplicity of 50 *Staphylococci* per leucocyte. Time is in minutes after the addition of *Staphylococci* to white cell suspension in Krebs-Ringer phosphate solution containing 20 per cent fresh guinea pig serum and 28 μ mol. of glucose in a final volume of 6 ml.

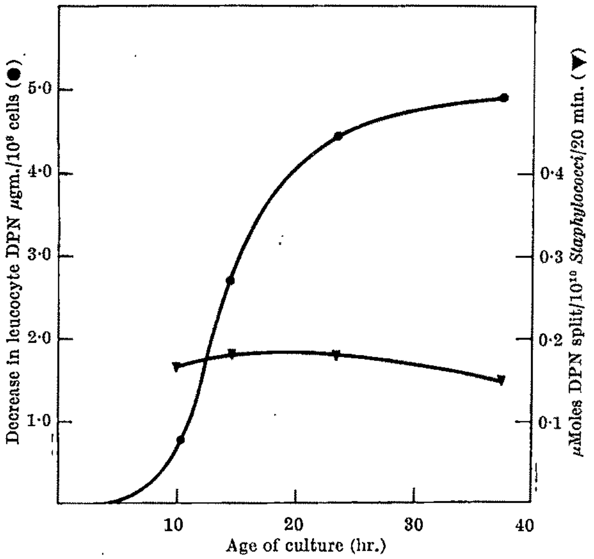

Fig. 2. Effect of age of *Staphylococci* (strain No. 241) in producing DPN decrease in white blood cells (average multiplicity of fifty). ● decrease in leucocyte DPN-levels induced by *Staphylococci* grown for varying number of hours ; ▼, specific activity of 'heat-activated' DPN pyrophosphatase obtained from *Staphylococci* grown for varying number of hours

observations were made at high multiplicities (50), significant effects were noted with boiled and unboiled organisms at multiplicities of 10 and 25 (Table 1). It became possible to demonstrate decreases in leucocyte DPN-levels with multiplicities as low as 2 or 5 when incubation was carried out in siliconized flasks in which mixing was more efficient than in polyethylene tubes. Under these conditions, about 75 per cent of the white cells contained *Staphylococci* on stained smear.

Of five strains of coagulase-positive *Staphylococcus aureus*, all possessing the 'heat-activated' DPN pyrophosphatase, four produced distinct drops in the DPN content of leucocytes, but one strain (No. 754) did not (Table 2). One strain of *Staphylococcus albus* possessing the enzyme produced a decrease in DPN content, whereas two other strains lacking the enzyme failed to do so. The number of strains tested is too small as yet to draw any general conclusions.

* Average multiplicity of fifty bacteria per leucocyte.

† +, present strain ; −, absent in strain.

The loss of pyridine nucleotides on interaction with *Staphylococci* is not a non-specific one resulting from interaction of any bacterium with leucocytes, as can be seen in Table 2. Three different strains of *Escherichia coli* did not lower the DPN-level of leucocytes. These organisms had no DPNase or DPN pyrophosphatase. Two strains of *B. subtilis* similarly had no effect, one of these, strain 'Brandeis' (kindly supplied by Prof. N. O. Kaplan), having a 'heat-activated' DPNase. *Proteus vulgaris* (ATCC No. 9484) had a DPN pyrophosphatase which was not 'heat-activated', but it failed to cause a drop in DPN-levels. Both strains of group A *Streptococci* tested produced profound drops in white blood cell DPN-levels. It is of interest to note that strain No. 30 that caused the greater decrease did not produce the extracellular enzyme DPNase, whereas strain No. 29 produced large amounts of this enzyme. Thus, it would appear that the presence of a DPN-cleaving enzyme in a micro-organism is not necessarily correlated with its ability to induce DPN loss in leucocytes. Bernheimer *et al.* have shown a rather striking correlation between DPNase production and leucotoxicity of streptococcal strains. However, they were unable to demonstrate injury to the leucocytes by a purified preparation of the extracellular DPNase. However, this did not eliminate the possibility that DPNase might be responsible for the leucotoxicity, since it was not known whether the enzyme had actually penetrated into the leucocytes.

The significance of the loss of DPN in white blood cells initiated by *Staphylococci* and its possible relation to the virulence of the organism remains to be elucidated. Work on the survival of intracellular *Staphylococci* in such depleted white blood cells as well as further work on uptake of oxygen, etc., should help to elucidate the significance of this biochemical lesion.

This investigation was supported (in part) by a U.S. Public Health Service research grant (*E*–1884) from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service.

RADIOASTRONOMY

A New Determination of the Solar Parallax by Means of Radar Echoes from Venus

During the recent close approach of Venus the Jodrell Bank radio telescope has been used to obtain radar echoes from the planet. The radar equipment, which operated at a frequency of 408 Mc./s., had a peak-power of 60 kW. and gave 30-m.sec. pulses at one pulse per second. The transmitter and receiver were operated alternately for periods of approximately five minutes, the light-time to Venus and back. To eliminate fading caused by Faraday rotation of the line of polarization of the signals in the Earth's ionosphere, an aerial system transmitting right circular polarization and receiving left circular was used. This was achieved by means of a feed aerial consisting of crossed coplanar dipoles and reflectors fed in quadrature from a hybrid ring, which also provided 40 db. of isolation between the receiver and transmitter. An electron-beam parametric amplifier (Adler tube) with a noise figure of 2 db. formed the input to the receiver.

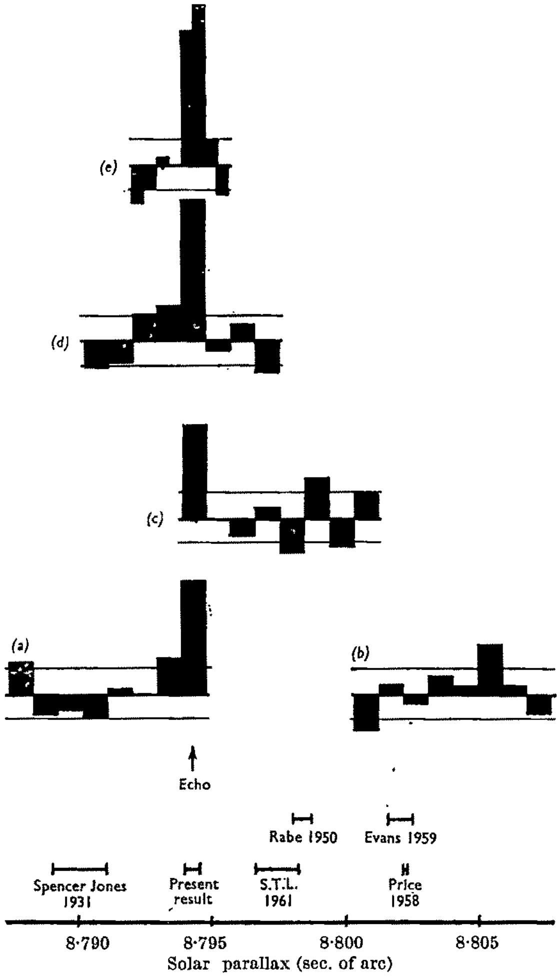

Fig. 1. Some recent determinations of the solar parallax are shown in relation to the present result. At (*a*), (*b*), (*c*) and (*d*) are shown histograms representing deviations from the mean of the eight integrator channels after twenty 5-min. periods of integration. The fine lines in each case represent one standard deviation. The range of Venus assumed on each occasion corresponded to the value of the solar parallax below the centre of each histogram; the echo always stayed in the channel corresponding to the present value. At (*e*) is shown the effect of halving the integrator channel width: the echo now divides equally between the two channels, confirming its central position

As the signal to noise ratio was expected to be less than unity a real-time integrator was used to detect the echo. The output of the final intermediate frequency amplifier, which had a band-width of 67 c./s., was applied to a linear detector; a variable frequency pulse output was then produced, linearly dependent in frequency on the detected voltage. The integrator sampled this pulse output at eight adjacent positions on the time base, each sampling period being 30 m.sec. The outputs from corresponding sampling periods on successive sweeps were counted in eight separate counting channels. Thus if only noise is present the counts in the eight channels will show random fluctuations about a mean, but if an echo is present the count in one channel will show a significant rise from the mean.

During the observations the range of Venus was changing by as much as a sampling period within a few minutes, so an automatic system was employed to alter the position of the sampling channels to keep the echo always within one channel. This system was accurate to within ±2 m.sec. The Doppler shift of the returned signals was changing by an amount equal to the receiver band-width every few minutes, due to the rate of change of the relative line of sight velocity, and therefore the receiver was tuned manually to keep it within ±3 c./s. of the predicted frequency. The whole spread of likely values of range was covered by three different settings of the sampling channels. Echoes were first detected on April 8, as soon as the equipment was operating correctly, and continued to be detected until observations ceased on April 25.

Fig. 1 shows some of the results, together with a chart of some other recent determinations of the astronomical unit, the values corresponding to the possible ranges of Venus explored. Each of the sections *a*, *b*, *c* and *d* shows the result of integrating for 20 receive periods assuming the value of the astronomical unit below the centre of the integration channel system. The lines on each side of the means represent one standard deviation. Also shown at *e* is the result of halving the sampling period in order to confirm the position of the echo more precisely; it will be seen that the echo is now divided equally to within a standard deviation between channels 3 and 4. The present result lies about half-way between the values of Rabe[1] and Spencer Jones[2], and is significantly lower than the recent Space Technology Laboratories[3] value.

Our result is:

Light-time for one A.U. = 499·011 ± 0·017 sec.
or
Solar parallax = 8·7943 ± 0·0003 sec. of arc

The computations of azimuth, elevation, range and Doppler shift needed for this work were made on the *Mercury* Computer in the University of Manchester. They were based on the *Astronomical Ephemeris* and the following values of constants were assumed:

Velocity of light	299,792·5 km./sec.
Equatorial radius of Earth	6,378·388 km.
Jodrell Bank radius of Earth	6,365 km.
Radius of Venus (ref. 4)	6,200 km.

The most likely cause of systematic error in the result is uncertainty as to the distance of the reflecting surface from the centre of Venus; it has been assumed that this is the same as the planet's radius. However, if the effective reflecting surface were closer to the centre by 7 per cent it would only make an increase of one part in 10^5 in the above value for the parallax, so that such an effect would be small compared with the limits of error.

A previous attempt to determine the solar parallax was made at Jodrell Bank during the close approach of Venus in September 1959[5]. After 350 receive periods—equivalent to 58¾ hr. of integration—a value of the solar parallax of 8·8020 sec. of arc was determined on the basis of an echo of 2½ standard deviations. This agreed with the Millstone Hill value obtained in 1958[6], but there was an 8 per cent chance that noise alone produced the rise in the counter channel which would appear to be a probable explanation of these earlier results.

A fuller account of this work, together with a discussion of the radio albedo of Venus, will be reported elsewhere when the tape recordings made during the observations have been analysed.

We wish to thank Sir Bernard Lovell for his interest and encouragement. Our technical assistant, A. C. Prior, designed and constructed the automatic ranging circuits and gave valuable assistance at all stages of the programme. This work was supported in part by United States Air Force Contract No. *AF*61 (052)–172.

ASTROPHYSICS

Observations of Satellite 1960 ζ1, and a Comparison with Satellite 1958 δ1

Since July, 1960, I have made observations of satellite 1960 ζ1 (*Midas* 2), as an exercise in prediction and visual tracking, and to study the damping of its spin. The following data and comments may be of interest to those engaged in precise analysis.

This satellite has given characteristic flashes, which are sharply defined when the satellite is between the Sun and the observer. This is in keeping with the now familiar experience that in 'crescent' illumination, the intensity of sunlight reflected from a satellite is most sensitive to change of profile, and superimposed specular reflexions. *Midas* 2 is normally a magnitude +3 object at close range, with infrequent flashes to magnitude +1; while at long range it is very much fainter.

Table 1 contains the data from my observations at this location, 34° 43′ S., 138° 42′ E. Timing the flashes by a simple stop-watch and binocular technique, the interval T containing N flash cycles can be determined usually to within 1 sec. The two observations made at long range, and therefore smaller angular velocity of transit, suggest a slight reduction of the observed flash period. It may be tentatively assumed that the cylinder is rotating in a direct sense about a transverse axis.

Table 1. Flash Period of Satellite 1960 ζ1, observed from Elizabeth, South Australia

Time of observation		Interval T (sec. ± 1)	No. of flash cycles, N	Mean flash period (sec. ± $1/N$)	Approximate orientation
S.A. time	G.M.T.				
1960					
July 18.781	18.385	27·0	5	5·40	65° N.N.E.
Oct. 21.826	21.430	31·6	5	6·32	60° N.N.E.
Oct. 22.808	22.412	38·7	6	6·45	60° N.
Nov. 23.128	22.732	33·8	5	6·75	50° N.N.E.
Dec. 7.868	7.472	13·8	2	6·9	60° N.N.E.
Dec. 8.851	8.455	34·5	5	6·90	60° N.N.E.
Dec. 9.833	9.437	96·2	14	6·87	55° N.E.→E.
1961					
Jan. 9.157	8.761	22·0	3	7·3	55° N.E.
Jan. 10.140	9.744	36·0	5	7·20	55° N.N.E.
		43·0	6	7·17	45° N.E.→E.

If the 'tumbling' period ($\frac{1}{2}P$) can be stated closely by the relation: $\frac{1}{2}P = T/(N + \theta/180)$, the deviation of the observed flash period from the true tumbling period is about +0·2 sec. in transits at 1°/sec. In the above equation, θ is the angle of movement of the line of sight during an observation.

The rotation period P has increased at a constant rate of 0·020 sec./day, from 10·5 sec. on July 18, 1960, to 14·0 sec. on January 8, 1961. During this interval, the orbital period has decreased only from 94·40 to 94·32 min.

It is of particular interest to compare the rate of decrease of angular momentum of spin for 1960 ζ1, with that for 1958 δ1 (*Sputnik* 3 rocket). Relevant details are set out in Table 2. The critical comparisons are between the respective values of the retarding couple $d(I\omega)/dt$ and the factors considered likely to determine these, principally the air density at perigee, and the length and profile area of each satellite.

Table 2. Factors relating to the Rotation of Satellites 1960 ζ1 and 1958 δ1

Physical data assumed	1960 ζ1	1958 δ1
Length, L (cm.) Diameter, D (cm.) Mass, M (gm.)	670 150 $2 \cdot 27 \times 10^6$	1,800 250 $4 \cdot 5 \times 10^6$
Moment of inertia (gm.-cm.^{2}) $I = M(D^2/16 + L^2/12)$	$8 \cdot 8 \times 10^{10}$	150×10^{10}
Interval considered	18/7/60 – 8/1/61	17/8/58 – 27/10/58
Angular velocity ω (rad./sec.) initial final	 0·60 0·45	 0·349 0·334
Angular momentum $I\omega$ (gm.-cm.^{2}/sec.) initial final extrapolated to $\omega = 0 \cdot 35$	 $5 \cdot 28 \times 10^{10}$ $3 \cdot 96 \times 10^{10}$ $3 \cdot 08 \times 10^{10}$	 $52 \cdot 35 \times 10^{10}$ $50 \cdot 10 \times 10^{10}$ —
Fraction of time spent near perigee, f	1·0	0·1
$d(I\omega)/dt$ (dyne-cm.) initial final extrapolated to $\omega = 0 \cdot 35$	 1,200 650 400	37,000 at $f = 0 \cdot 1$ 3,700 at $f = 1 \cdot 0$
Mean air density at perigee (gm.-cm.$^{-3}$)	$2 \cdot 6 \times 10^{-15}$	$2 \cdot 5 \times 10^{-13}$

The dimensions of 1958 δ1 are not accurately known. Notni and Oleak[1] derive from data by King-Hele[2] the relation $\rho DL/M = 2 \cdot 86 \times 10^{-14}$ cm.$^{-1}$, where ρ is the air density at perigee (approximately 3×10^{-13} gm.cm.$^{-3}$). The rocket may have been heavier than the *Atlas* satellite (1958ζ), so M may have been as high as 5,000 kgm. From the observed brightness and large fluctuations of brightness, it is reasonable to expect $L \sim 20$ m., with $L \gg D$, while consideration of mechanical design suggests $L < 10D$. Assuming that the rocket body tapered to the base of the instrumented cone

(1958 $\delta 2$), (diameter 170 cm.), the data used in Table 2 are: $D=250$ cm., $L=1{,}800$ cm., $M=4\cdot 5\times 10^5$ gm.

The retarding couple acting on 1958 $\delta 1$, concentrated in the transits through perigee ($f=0\cdot 1$), is of the order of 100 times greater than that acting on 1960 $\zeta 1$ at comparable rate of spin. This would explain satisfactorily the relative changes in terms of air friction, if the two satellites were known to be similar in weight and size. However, because 1958 $\delta 1$ was of such lower density and greater length, it is possible that the couple on it was much too small to permit this explanation, unless gross errors are present in the physical data assumed in Table 2.

If damping of satellite spin by the Earth's magnetic field is the controlling factor, even for the large empty rocket at a height of 220 km., the couple on 1958 $\delta 1$, averaged over the orbit ($f=1\cdot 0$), would be only about 10 times greater than that on 1960 $\zeta 1$. It is this possibility which I offer for critical analysis, in the light of the recent discussion[3] of the rotation of 1958 $\delta 1$.

The relative values of $d(I\omega)/dt$ would be even closer if either the weight or the moment of inertia of 1958 $\delta 1$ were appreciably less than assumed in Table 2.

PHYSICS

Thermal Shock Behaviour of Brittle Materials

WE have been investigating the thermal shock behaviour of some glasses and other materials, using an argon plasma jet, as a preliminary part of an investigation into the thermal shock behaviour of brittle materials. The plasma jet was used in this investigation since it affords an easy and reliable method of producing very high heat transfer-rates of the order of 400–500 cal./cm.^{2}sec. In the present experiments the samples, in the form of disks $\frac{1}{2}$ in. thick and $\frac{7}{8}$ in. diameter, could be shocked every 2 sec. for up to 1,000 times, the shock itself lasting about $0\cdot 16$ sec. Under these conditions it was possible to obtain surface melting on such materials as soda glass, borosilicate glass and an electrical porcelain.

It was found, as a general rule, that where no surface cracking occurred during a single shock no cracking would be produced at all however many times the shock was repeated up to the maximum tried of 1,000 shocks. At low heat loadings, however, often nothing would be apparent on visual examination but cracks would appear later, sometimes weeks later, which were of a different form from those produced during a single shock. For example, with soda glass no cracks were observed by eye at heat loadings of 75 cal./cm.^{2}sec. until several days after the experiment, when patterns of the type in Fig. 1 or Fig. 2 were produced. Fig. 1 indicates a shearing of the heated glass from the remainder and Fig. 2 shows cracking, in tension, of the surface during cooling. At higher heat loadings cracking occurred immediately (Fig. 3). Fig. 3 shows a series of shallow cracks generally radiating out from the central hot zone whereas Figs. 1 and 2 show only one or a few deep cracks. The surface completely disintegrated at the highest heat loading tried, 400 cal./cm.^{2}sec., into a fused cracked mass, but again none of the cracks extended into the body of the disk.

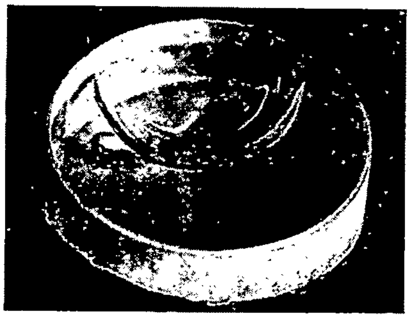

Fig. 1. Soda glass after 500 shocks at 75 cal./cm.^{2}sec. Sheer crack during cooling

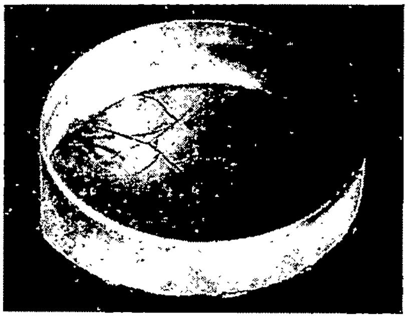

Fig. 2. Soda glass after 500 shocks at 75 cal./cm.^{2}sec. Tensile cracking during cooling

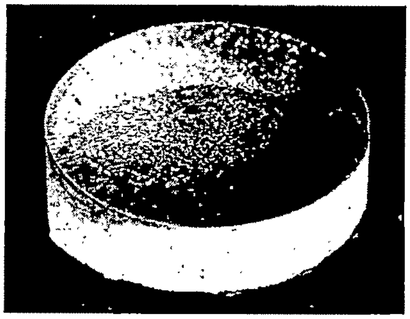

Fig. 3. Soda glass after 1 shock at 400 cal./cm.^{2}sec.

The results obtained with a borosilicate glass were similar to those observed with soda glass, except that a greater heat loading was required to produce similar effects. No effects were observed at all with 75 cal./cm.^{2}sec. but at 150 cal./cm.^{2}sec. cracking of the types shown in Figs. 1 and 2 was found. At the higher heat loadings surface cracking and melting occurred. No surface cracks could be produced on silica with heat loadings in the range 75–400 cal./cm.^{2}sec. but it was found that, on leaving for several months, the two samples which had received 100 shocks at 400 cal./cm.^{2}sec. were cracked, one as in Fig. 1 and the other as in Fig. 2.

Electrical porcelain behaved similarly to the borosilicate glass. Typical samples are shown in Figs. 4 and 5. One unusual feature of these results was that the electrical porcelain often cracked into two halves, the crack following the path of the jet across the surface, whoreas the only glass to crack bodily was the

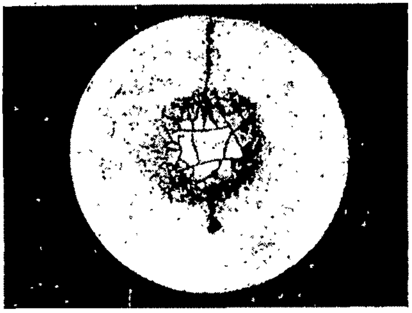

Fig. 4. Electrical porcelain after 1,000 shocks at 150 cal./cm.²sec. Note major cleavage crack in path of jet across surface

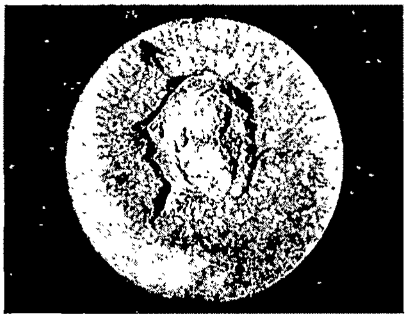

Fig. 5. Electrical porcelain after 10 shocks at 400 cal./cm.²sec.

soda glass and that did so normal to the path of the jet.

This work forms the initial stage of a fundamental study of the thermal shock behaviour of ceramic materials. I wish to thank Mr. Dugdale of the Metallurgy Division, United Kingdom Atomic Energy Authority, Harwell, for his advice and help during the earlier part of this investigation.

The Parametric Line: a Photon and Gravitational Field Analogue

Let E and v be the energy and velocity of a pulse in a 'parametric line'[1], denoting the input and output ends by the subscripts 1 and 2 respectively. It has been shown[1] that the pulse energy amplification factor has the form:

$$E_2/E_1 = v_2/v_1 \qquad (1)$$

If this factor does not differ very much from unity, it can be written in the form:

$$E_2/E_1 = [\{(L/T)(v_2 - v_1)\}/\{\tfrac{1}{2}(v_1 + v_2)\}^2] + 1 \qquad (2)$$

where L is the length of the line, T is the time necessary for traversing the line and $\frac{1}{2}(v_1 + v_2)$ is the average speed of the pulse along it.

According to the General Theory of Relativity, an electromagnetic wave packet running over a length l in the direction of a gravitational field of intensity g (units of acceleration) gains frequency and hence energy[2]. The initial and final energies (ε_1 and ε_2) are related according to:

$$\varepsilon_2/\varepsilon_1 = 1 + \{gl/c^2\} \qquad (3)$$

where c is the velocity of light.

An analogy between equations (2) and (3) is established by substituting c for $\frac{1}{2}(v_1 + v_2)$, g for $(v_2 - v_1)/T$, l for L and ε for E. It will be noted that in each case the substitutions have the same dimensions.

Another analogy can be derived by considering the frequency spectrum of the pulse. Denoting the spread of the frequency by f and the duration of the pulse by τ, it follows from Fourier's theorem that:

$$\tau_1 f_1 = \tau_2 f_2 \simeq 1 \qquad (4)$$

It has been shown that in a parametric line (ref. 1):

$$\tau_1/\tau_2 = v_1/v_2 \qquad (5)$$

It follows from (4), (5) and (1) that:

$$E_1/f_1 = E_2/f_2$$

This equation resembles the energy frequency (ε, ν) relation

$$\varepsilon/\nu = h$$

where h is Planck's constant.

Fareham, Hants.

[1] Physical Society Exhibition (demonstration 1960), further details to be published (*Phys. Soc. Handbook 1960*, p. 104).

[2] Wilson, H. A., *Modern Physics*, 6, 332 (Blackie and Sons). Equation (3) may be derived by considering a small distance dr in which the field is considered uniform and by substituting ordinary units for the special units used. dt'/dt is taken to be equal to $v_2/v_1 = \varepsilon_2/\varepsilon_1$. See also *Electronic Technology*, 39, No. 7, 267.

Standard Unit of Pressure in Vacuum Physics

It is regrettable that spokesmen for the Bureau International des Poids et Mesures[1] and the Standards Division of the National Physical Laboratory[2] have failed to understand my recent communication[3].

Previous work on standardization has unfortunately resulted in the use of two units in the vacuum field, not related decimally to each other: millibar and torr, the latter being not equal to mm. of mercury[4]. My endeavour was to propose a practical solution to this problem much discussed by vacuum physicists and technologists in recent years. An attempt, therefore, was made to define a new unit which, being decimally related to both mm. mercury and C.G.S. (and M.K.S.) unit of pressure, could be considered as the standard unit of pressure in vacuum physics. The unit proposed, which was conveniently termed 'vac', should not be confused with millibar, as was done by the commentators mentioned above, the millibar invariably being nothing else than a multiple of the absolute unit of pressure, while the vac is defined in terms of the height of the mercury column under specified conditions. The new unit does not bring great implications in practical use. It represents an acceptable compromise to satisfy the international systems of units, and to avoid the replacement of mm. mercury by an arbitrary unit, like the torr.

I may mention that a detailed discussion of this matter has been reported elsewhere[5].

N. A. Florescu

School of Physics,
University of New South Wales,
Kensington, Sydney.

[1] Volet, Ch., *Nature*, 188, 1017 (1960).

[2] Bigg, P. H., *Nature*, 188, 1017 (1960).

[3] Florescu, N. A., *Nature*, 188, 303 (1960).

[4] British Standards Inst., B.S. 2951 (1958).

[5] Florescu, N. A., Rep. VP-1 (School of App. Phys., Univ. N.S.W., 1960).

In order to obtain a unit of pressure in terms of the height of a column in a liquid manometer, a unit which is also related decimally to absolute units of pressure, Dr. Florescu proposes to elevate the pressure due to a 0·75-mm. column of liquid of density 13·5951 gm./cm.^{3}, g being 980·7455 cm./sec.^{2}, to the status of a new unit, and call it the 'vac'. But as Dr. Florescu admitted originally, this pressure is effectively 10^3 dynes/cm.^{2}, called internationally the millibar, and for the practical purposes of vacuum technology the pressure due to ¾ mm. of a standard mercury column (density 13·5951 gm./cm.^{3}, standard gravity 980·665 cm./sec.^{2}) is one millibar (more closely it is 0·999 92 mb.). Quite apart, therefore, from Dr. Volet's point, with which I entirely agree, I see no justification for introducing a new unit, the 'vac', the definition of which involves a new, arbitrary reference gravity, when the scale it would provide would in vacuum practice be indistinguishable from a scale of millibars.

METALLURGY

Anomalous Magnetostriction of the 'Grain-orientated' Silicon-Iron Sheet

This communication is concerned with the anomalous phenomenon occasionally found in examining the magnetostriction of the 'grain-orientated' silicon-iron sheets, and it was believed to be a prime cause which gives rise to a transformer noise. The method of measurement is the static one which has been adopted by us for a long time[1], and by this method the mean value of magnetostriction can be obtained. The experiments were carefully made with respect to a thin plate-like specimen.

The specimen contains 4·35 per cent silicon, and is used by a trade name of 'T-90' in Japan. The specimen is a rectangular plate, 0·37 mm. thick, 6 mm. wide and 10 cm. long, and the direction of length corresponds to that of measurement and rolling. Fig. 1 shows a result for the specimen annealed at 600° C. for 1 hr. after cutting down the specimen from a large sheet.

As shown in Fig. 1, the magnetostriction does not appear up to 100 c.g.s. and then increases gradually, showing a minimum just before saturation with the increasing intensity of magnetization, and lastly, increases abruptly to a saturation value. It will be due to the 180° wall displacements that the magnetostriction does not appear in the first step. Adequate interpretation of this phenomenon may be very difficult, but we reasoned as follows.

In general, in iron-base alloys, including the 'grain-oriented' iron-silicon sheets, the magnetostriction is positive in an easy direction, and is negative in a hard direction. Therefore, the magnetostriction of polycrystal specimen is the sum of both values mentioned above, so that it is ordinarily encountered that the magnetostriction curve is either parabolic or exponential.

Now, in the range of continuous rotation of domain in the magnetization process, the mechanism of rotation may be greatly affected not only by the intrinsic crystal magnetic anisotropy but also by the additive restraint force or uniaxial anisotropy induced by rolling.

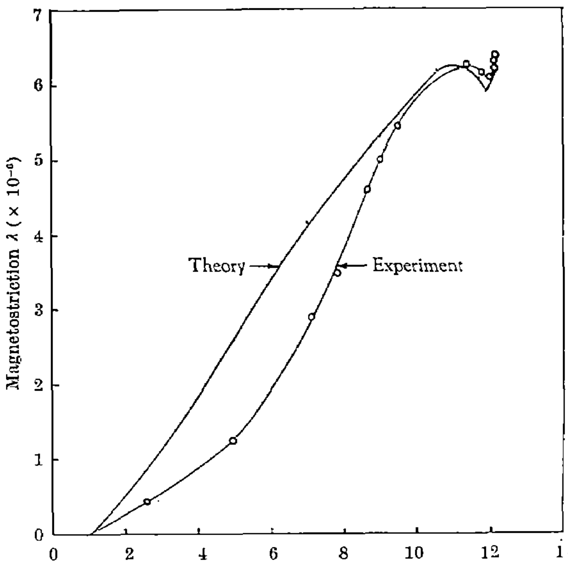

Fig. 1. Anomalous magnetostriction curves obtained experimentally and theoretically in the 'grain-orientated' silicon-iron sheet

Some amount of the restraint force mentioned above may coincide with a special direction near an easy one. If so, in this direction, the domain rotations may be restrained, hence the magnetostriction does not appear below a critical magnetic field the energy of which surpasses the restraint force.

In such a way, the anomalous curve shown in Fig. 1 may be explained. Next, the simple theoretical expression may be given according to Heisenberg's theory of magnetostriction in the unsaturated magnetization region[2].

Using the above results and the magnetostriction constants obtained by Shturkin[3], and assuming that the fractions of orientation <100>, <110> and <111> are 0·3, 0·6 and 0·1 respectively, the theoretical magnetostriction can be calculated as shown in Fig. 1. A good agreement exists between the theoretical and the experimental results.

Formation of Silicon Nitride Whiskers on a Ferro-Silicon Alloy at Room Temperature

After approximately ten years of operation, a calcium carbide furnace at Odda Smelteverk A/S, Norway, was temporarily stopped. At the bottom of the furnace a phase containing a ferro-silicon alloy was found. A sample taken from this bottom phase was kept in contact with air at room temperature. After a few weeks, formation of greyish-brown whiskers on the surface of the sample was observed.

These whiskers were removed, but after an additional few weeks needle-shaped crystals were again formed. This process has been repeated up to now, about one and a half years after the sample was taken out of the furnace. At present, however, the crystal growth seems to have almost ceased.

Chemical analysis of the sample on which the crystals grew gave the following result (weight per cent): iron, 82·4; silicon, 14·5; carbon, 2·85; calcium, 0; nickel, manganese, cobalt, vanadium, copper, titanium—minor impurities.

A metallographic investigation showed clearly that this substance contained only one ferro-silicon phase, the α-phase. The carbon appeared as a separate graphite phase.

The crystals forming the whiskers were investigated by X-ray analysis. From the powder diagrams, *d*-spacings were calculated. They were in almost perfect agreement with the X-ray lines given by Popper and Ruddlesden[1] for α- and β-Si_3N_4. Both allotropic forms were present in the crystals investigated.

The results of a quantitative chemical analysis of the crystals correspond to the composition $Si_{3\cdot 04}N_4$.

Earlier investigations[2,3] describe cases where Si_3N_4 was formed during, for example, the nitriding process for case-hardening of steels containing small amounts of silicon. But in all cases the nitride was formed at temperatures not lower than 250° C.[4]

The results reported here, however, clearly demonstrate the formation of α- and β-Si_3N_4 on a lump of a ferro-silicon alloy even at room temperature. The kinetics of this process will be discussed elsewhere.

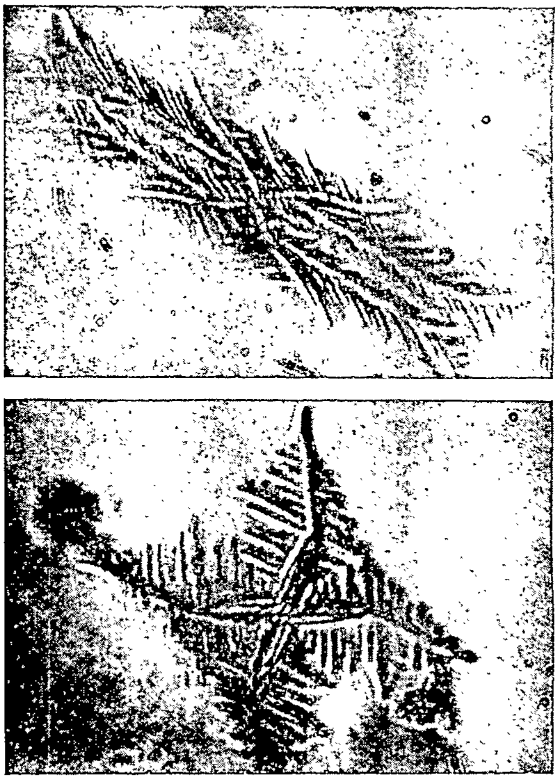
CRYSTALLOGRAPHY

Some Features of the Precipitation of Barium Chromate by an Extra-slow Technique

In the course of experiments concerning the preparation of very pure compounds, the precipitation of barium chromate was chosen as a model. S. Rykowski and I found[1] that a very slow precipitation with dilute solutions produces a precipitate which contains very minute crystals known as 'crystal skeletts'.

Continuing this work I have developed a technique of extremely slow precipitation, and I have observed some interesting features as regards the shapes of the crystals (see Fig. 1). A precipitate was obtained by addition of a dilute barium chloride solution to a large volume of potassium chromate solution and steady and vigorous mixing. After some hours minute crystals could be seen under the microscope (× 720–2,000). These crystals showed strikingly perfect symmetry, and some had regularly curved shapes. Besides the X-shaped crystals, very regular hexagonal plates and other more complicated forms appeared.



Figs. 1 and 2

When ammonium chromate instead of potassium chromate solution was used, crystals of similar shapes were formed. Addition of potassium chloride (150 gm./l.) to the solution of potassium chromate produced exclusively crystals of the hexagonal type.

When a mixture of barium nitrate and silver nitrate (10: 1) was added to the solution of potassium chromate X-shaped crystals were formed. These crystals consisted of two parts of different shape and colour. It is assumed that the larger one is formed of barium chromate (pale yellow) the other one being silver chromate (dark brown) (see Fig. 2).

Barium sulphate and barium phosphate precipitates also showed interesting shapes of similar character.

Details of this work, which is being continued, will be published elsewhere. I wish to thank Mr. L. Trojanowski for his assistance.

Retention of Carbon Dioxide Bubbles on Calcite Etch-Peaks

The etch-patterns on cleavage faces of calcite which have been reported[1–3] bear some interesting similarities and dissimilarities to etch-patterns obtained in this Laboratory. Watts etched calcite for 30 sec. in 1 per cent nitric acid and obtained fivesided figures which he called pits. We immersed calcite in 0·001 N hydrochloric acid for one week and obtained essentially six-sided peaks (Fig. 1) with irregular valleys between them. The sixth side has a rougher surface than the other sides and it seldom extends to the apex of the peak. It may constitute an incompletely formed figure. Stanley used 10 per cent hydrochloric acid for 10–60 sec. and obtained figures which he describes as four-sided, although from his published photographs we detect a tendency of these figures toward the six-sided etch-patterns observed in our study. The Pandyas, using ammonium chloride, obtained parallelograms.

Another curious phenomenon was observed in this investigation. After the acid-carbonate reaction had proceeded long enough to etch the calcite surface, new carbon dioxide bubbles were nucleated on peaks of the etch-figures and remained there during their periods of growth (Fig. 2). A bubble would remain on a peak for a few seconds to many minutes, depending on the rapidity of the reaction. Escape of the bubble was followed quickly by the appearance of a new one on the same site. When such bubbles are viewed in silhouette, a gaseous stem is seen holding the bubble to the solid surface (Fig. 3). The end attached to the calcite remains stationary while the bubble is wafted to and fro by gentle currents in the acid solution. The remarkable 'contact angle' contrasts sharply with the attitude of carbon dioxide bubbles which form on uncleaned cleavage surfaces promptly after immersion in the dilute hydrochloric acid (Fig. 4).

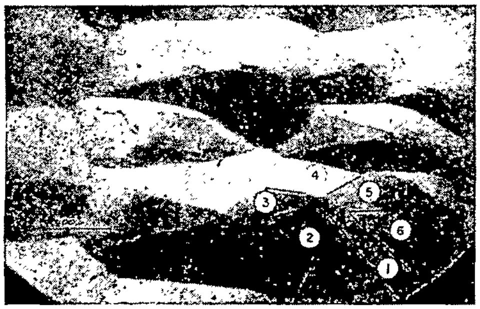

Fig. 1. Etch figures on calcite, magnification, × 87 ; illumination from top of page

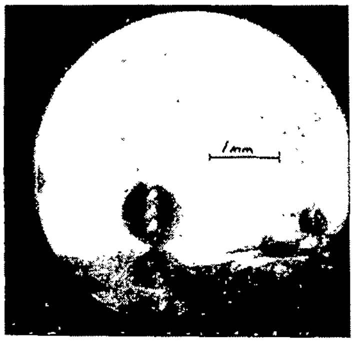

Fig. 2. Bubbles formed after etching, magnification, × 9

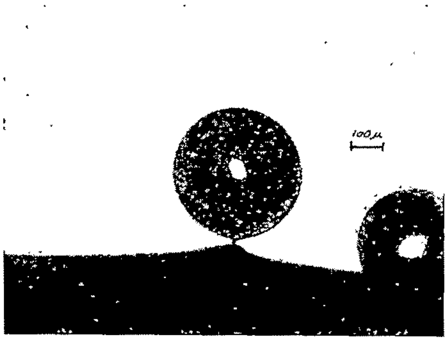

Fig. 3. Silhouette view of bubble on etch-peak, magnification, × 40

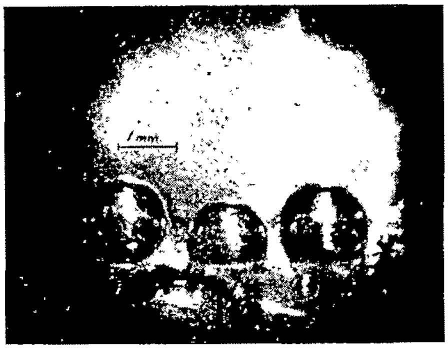

Fig. 4. Bubbles formed upon first contact of acid with calcite, magnification, × 7·5

The etch-peaks in Fig. 1 show a pinched appearance. It is suggested that this added erosion occurs during the up-sweep of comparatively strong acid that follows the escape of a bubble from the peak.

GEOLOGY

Stilpnomelane in North Wales

THE occurrence of stilpnomelane in Great Britain was first recorded by Hallimond[1]. He described the mineral from the Pen-y-rallt mine in Merionethshire, where it occurs in a pisolitic ironstone bed at the contact with "a mass of igneous rock". The mineral occurs in association with chalybite in roughly parallel asbestiform veins up to one inch wide.

Present investigations in the region between Arthog and Dolgelley, Merionethshire, have shown that stilpnomelane is very common in certain basic marginal phases of the post Lower Llanvirn Cregennen granophyre sheet and in the associated 'markfieldites'. The mineral also occurs in some vitric (? welded) acid tuffs of the Lower Llanvirn Bryn Brith Series[2].

The analysed stilpnomelane-bearing granophyre from the upper contact zone consists essentially of quartz (generally granophyric), a little orthoclase, plagioclase (albite-oligoclase), and iron-rich chlorite mainly replacing actinolitic amphibole. Apatite is abundant together with ilmenite and sphene.

Stilpnomelane occurs as sharply terminated laths which are commonly arranged in either radiating sheafs or as 'bow-tie' aggregates. It appears to be the last mineral formed in the rock and replaces chlorite and feldspar. It is also a constituent of small veins and fills occasional druses in the rock. The mineral is intensely pleochroic from pale yellow to a deep golden-brown or black and often shows varying degrees of alteration to a sub-isotropic reddish-brown vermiculite. The form and general characters of the mineral are identical with those of stilpnomelane from California[3].

A chemical analysis of the stilpnomelane-bearing granophyre gave the following: SiO_2 58·97, TiO_2 1·93, Al_2O_3 14·31, Fe_2O_3 2·10, FeO 9·21, MnO 0·21, MgO 2·37, CaO 2·76, Na_2O 4·60, K_2O 0·14, H_2O^+ 3·08, H_2O^- 0·14, P_2O_5 0·78, CO_2 0·00. Total 100·60 (analyst T. W. Bloxam). Detailed optical and chemical analyses of the stilpnomelane will be given in a later communication.

The mode of occurrence and relationships of the mineral are very similar to those of the stilpnomelane[4] from the Skaergaard intrusion, east Greenland. It is probable that the 'biotite' from the Cregennen granophyre[2] is in fact stilpnomelane—a conclusion which is supported by the low K_2O-content of the analysed rock.

Stilpnomelane in the acid tuffs has the same form as that in the basic granophyres, but shows less alteration to vermiculite. Frequently adjacent fibres are orientated at right angles to each other producing a type of 'mesh-structure' in thin sections[5]. The mineral replaces chlorite infillings of small vesicular aggregates and also fine-grained ashy material in the ground-mass.

We suggest tentatively that the stilpnomelane is a product of post-granophyre metasomatism accompanied by low-grade metamorphism equivalent to the chlorite sub-zone one[6]. Woodland[7] has already described the Cambrian (Harlech Series) north of the present area, and has noted the progressive metamorphism of these rocks.

Lower Purbeck Beds of Swindon Facies in Dorset

IN the course of a yet unpublished study of the pseudomorphs after gypsum prevalent in the 'Purbeck Caps' and 'Broken Beds' of Lower Purbeckian age in Dorset, a marl has been discovered with a fauna resembling that of the freshwater facies of the 'Swindon Series'. In the well-known Portisham quarry with the 'fossil elephant' (a silicified tree trunk[1]), the three-foot "impure marls with seams of chert" listed by Woodward[1] as occurring 9 ft. 6 in. above the Portland Stone have been found to contain the Swindon ostracod *Ulwellia papulata* Anderson, and well-preserved charophytes in abundance. Gastropods are also abundant and perhaps have Swindon affinities. None of these has been recorded before in British strata of indisputably Lower Purbeck age, and a full palæontological investigation of the fauna is at present proceeding.

Lithologically the similarity in facies between the Dorset and Swindon beds is also well marked, and it is only with difficulty that the carbonaceous conglomeratic marl of Portisham can be distinguished from that of Swindon. At the former locality, however, there has occurred at places within this marl, the penecontemporaneous introduction of epigenetic lenticular gypsum. The geochemical conditions seem to have favoured silicification, which must here have been largely selective. The freshwater fossils are well preserved, and their presence in a rock full of pseudomorphs would seem at first sight to be anomalous. This appears to be due to the intercalation of the freshwater marl in an evaporitic succession marginal to the main gypsum deposits. These main gypsum deposits were rarely less than 6 ft. thick in the Broken Beds of the Lulworth region, where the 'Caps' were also very gypsiferous; at Portsdown and Henfield, anhydrite is dominant in the lower part of the Lower Purbeck[2].

At Swindon the freshwater nature of the greater part of the 'Swindon Series' has long been clear and they can be correlated with the Purbeck Beds of the Aylesbury district; but their correlation with the Purbeck Beds of Dorset has not previously been possible. A very thorough and painstaking investigation of these beds by Sylvester-Bradley[3] led to the realization that the fauna and flora, although differing in detail, were of a facies which at that time was known from Dorset only in the Middle Purbeck Beds. Twenty years ago Arkell and Sylvester-Bradley[4] discussed the age of the 'Swindon Series'. Arkell was convinced the evidence pointed to a Middle Purbeck age, but the view that the new discoveries strikingly support was that put forward by Sylvester-Bradley, who considered that the absence of *Cypridea granulosa* (Sow.) and *Cypridea fasciculata* (Forbes) suggested Lower Purbeck age.

CHEMISTRY

Activity-based Diffusion Coefficients for Liquid Solutions

WHETHER an equilibrium concept is applied to a consideration for diffusion in liquids or whether the methods of irreversible thermodynamics[1,2] are used, it is clearly established that the driving force for molecular diffusion in liquids, such as occurs in the well-known diaphragm cell, is the gradient of the chemical potential. However, it has been the common practice to report diffusion coefficients calculated on the basis of concentration gradients as the driving force rather than the gradients of the chemical potential.

For the case of a binary (components A and B) non-ideal liquid system, the usual barycentric diffusion coefficient, D (that is, taken with respect to the mass average velocity) is defined as follows[2,3] :

$$D = \mathfrak{D} \cdot \frac{\partial \ln a}{\partial \ln x} \qquad (1)$$

where $\mathfrak{D}$ is the binary activity-based diffusion coefficient, a is the activity of either component, and x is the corresponding mole fraction. The coefficient, $\partial \ln a/\partial \ln x$, is a measure of the deviation from ideal solution behaviour with a value of unity for ideal solutions. With $\partial \ln a/\partial \ln x$ accounting for such deviation, it would appear that $\mathfrak{D}(x)$ should not be affected by non-ideality since, being essentially a proportionality constant, it may be expected to be independent of the driving force associated with it. On this basis, it appears reasonable that the form of the function $\mathfrak{D}(x)$ should be the same for all binary systems, that is, the same as observed for ideal solutions. Data on some very nearly ideal solutions[4] do indicate that the form of the function $\mathfrak{D}(x)$ is a straight line or very nearly so.

Recent work by us[5] has provided extensive data on the ethanol–water system at 25° C. in agreement with earlier results[6]. The true or differential diffusion coefficients reported in both cases are D-values based on concentrations, and thus include corrections for non-ideality. Following equation (1) these results have been combined with the coefficients $\partial \ln a/\partial \ln x$ as computed by Guggenheim[7], using the vapour-pressure data of Dobson[8], on the assumption that

$$\frac{\partial \ln a}{\partial \ln x} = \frac{\partial \ln p}{\partial \ln x} \qquad (2)$$

where p is the partial pressure of the component with mole fraction x. Fig. 1 presents the results. The peculiar shape of this curve suggests the possibility of errors resulting from the difficulty of finding accurate shapes of vapour-pressure curves based on ten experimental points distributed over the total concentration range. This has been checked by integrating equation (1), using equation (2), starting from the pure component, and assuming that $\mathfrak{D}(x)$ is linear. This latter assumption, applied to the ethanol–water system, means that $\mathfrak{D} = 1{\cdot}22$ is constant. Using tabular integration, the partial pressures of ethanol and of water were determined at a series of compositions. The calculated pressures are shown on Fig. 2 by the continuous curves, together with the experimental points obtained by Dobson. The Duhem–Margules equation was used. Agreement with the experimental values being quite good, the use of a straight line for $\mathfrak{D}(x)$ does seem valid for this case.

Johnson and Babb[9], however, by applying similar corrections to their diffusivity data on the systems methanol–benzene and ethanol–benzene, obtained curves for $\mathfrak{D}(x)$ that vary by more than 100 per cent and in no way approximate linearity. For the case of the methanol–benzene system they used the data by Scatchard *et al.*[10] at 35° C., which they corrected to 25° C. by an unspecified method.

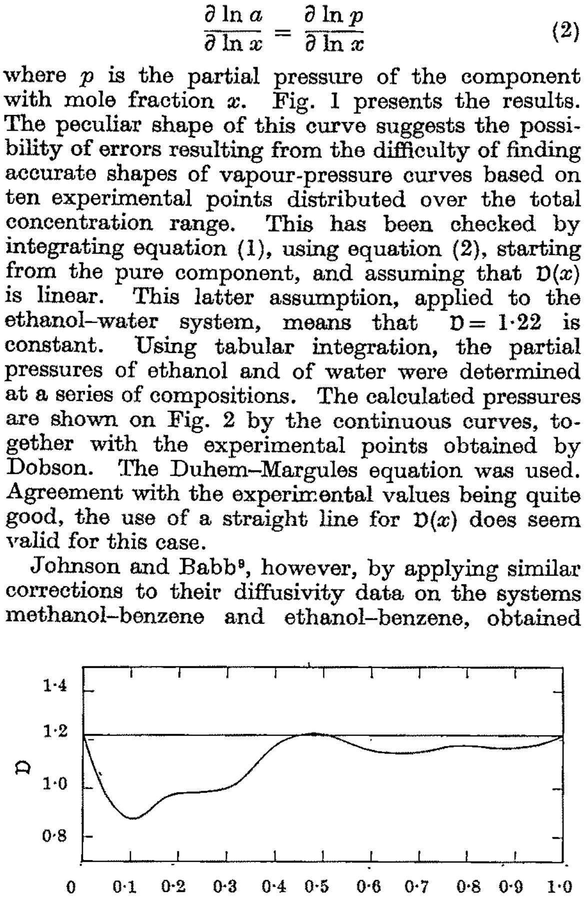

Fig. 1. Activity-based diffusivities in the ethanol – water system at 25° C., based on $\partial \ln p/\partial \ln x$ data as given by Guggenheim, and on measured values of D presented in ref. 5

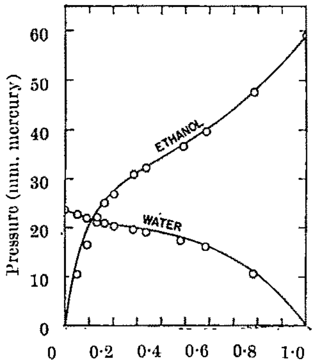

Fig. 2. Equilibrium vapour pressures (fugacities) in the ethanol – water system at 25° C. Continuous curves calculated by the equations,

$$D = \mathfrak{D}\,\frac{\partial \ln f_{\text{ethanol}}}{\partial \ln x_{\text{ethanol}}} = \mathfrak{D}\,\frac{\partial \ln f_{\text{water}}}{\partial \ln x_{\text{water}}}$$

using measured values of D, and $\mathfrak{D} = 1{\cdot}22$ cm.^{2}/sec., and assuming that the pure vapours behave as ideal gases. The circles denote experimental partial pressure values by Dobson (ref. 8)

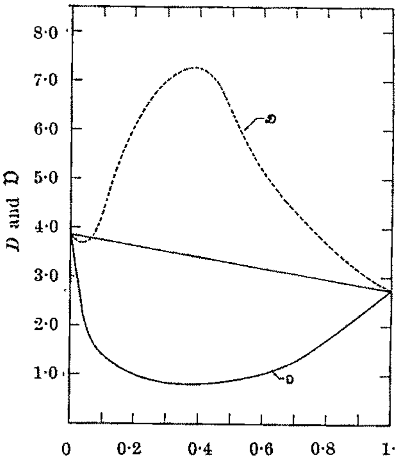

Fig. 3 Measured diffusivities D, and activity-based diffusivities, $\mathfrak{D}$ in the methanol – benzene system at 25° C., after Babb and Johnson (ref. 9)

This result, if correct, would certainly negate any speculation concerning the linearity of the function $\mathfrak{D}(x)$. There is little doubt that the vapour–liquid equilibrium data, as well as the measured diffusion coefficients, are essentially correct. There is a possibility of error in correcting the activity data to 25° C. To check this, the same integration procedure as used for the ethanol–water system was applied, using equation (1) for the measured diffusivities and the $\mathfrak{D}(x)$ curve by Johnson and Babb (Fig. 6, *loc. cit.*, and reproduced in Fig. 3). The curves then obtained are plotted in Fig. 4 as broken lines. It is noted that these curves do not pass through one point at 25° C. reported by Scatchard *et al.* The conclusion can be reached, however, that had Johnson and Babb used measured vapour-pressure curves at 25° C. to calculate $\mathfrak{D}(x)$, they would have obtained an even higher peak for this latter curve. In our opinion, the

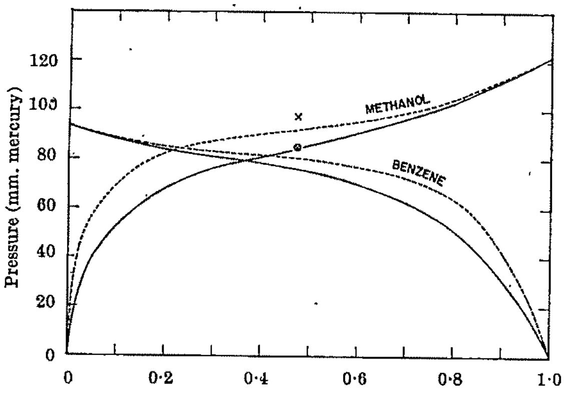

Fig. 4. Full lines are the fugacities in the methanol – benzene system at 25° C., as computed by the equations,

$$D = \mathfrak{D}\,\frac{\partial \ln f_{\text{methanol}}}{\partial \ln x_{\text{methanol}}} = \frac{\partial \ln f_{\text{benzene}}}{\partial \ln x_{\text{benzene}}}$$

using diffusivities given by Babb and Johnson (ref. 9) and a straight-line relationship for $\mathfrak{D}$. Broken lines show apparent values obtained by using the dashed curve on Fig. 3. × and ⊗ are measured partial pressures of methanol and benzene, respectively, after Scatchard *et al.* (ref. 10)

reason for the anomalous behaviour of the functions $\mathfrak{D}(x)$ as computed by Johnson and Babb, is the fact that benzene vapours do not form ideal mixtures with ethanol or methanol vapours. In the case of methanol at least, this has been experimentally verified by the observation of large heats of mixing in the system methanol vapour–benzene vapour[11]. Under such conditions equation (2) should be replaced with the more general equation :

$$\frac{\partial \ln a}{\partial \ln x} = \frac{\partial \ln f}{\partial \ln x} \qquad (3)$$

where f is the fugacity of the component with mole fraction x. In such a case experimental vapour-pressure data obviously cannot be used for the purpose of making activity corrections. The calculated curve $\mathfrak{D}(x)$ of Johnson and Babb, based on an erroneous assumption, cannot be considered as an argument against the suggested linearity of the function $\mathfrak{D}(x)$. It is of interest to calculate the fugacities of the two components over methanol–benzene mixtures at 25° C. using the experimental diffusivities of Johnson and Babb and a straight-line relationship for $\mathfrak{D}(x)$ between the two end-points of the diffusivity-mole fraction curve. The relationship :

$$D = \mathfrak{D} \cdot \frac{\partial \ln f}{\partial \ln x} \qquad (4)$$

was used together with the vapour-pressures of the pure components. The curves obtained are plotted also on Fig. 4 as continuous lines. As might be expected, the relative deviation between the two curves increases monotonically from the pure component end and, eventually, stays constant at a maximum 'saturation' value.

It may thus be proposed tentatively that the measured diffusion coefficients, in conjunction with a straight-line relationship for the activity-based diffusion coefficient be used to calculate the coefficient $\partial \ln a/\partial \ln x$, and hence the activities in the liquid solution, and the fugacities in the equilibrium vapour, for binary solutions of non-electrolytes. This procedure would be simpler than existing methods, and would also eliminate the necessity for differentiation, which should result in a considerable improvement in accuracy. It is hoped that by making isothermal diffusivity and vapour–liquid equilibrium determinations on a number of non-ideal systems, along with investigations of the vapour-phase for possible deviations from ideal solution behaviour, it will be possible to subject the above suggestion to more extensive testing.

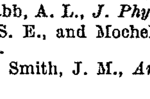
Complex Hydrides of Platinum

FOLLOWING a recent investigation of the structure of some rhodium(III) and iridium(III) tertiary arsine complexes[1], which were shown to contain a metal-hydrogen bond, we have examined certain tertiary phosphine compounds of platinum and suggest that these also are complex metal hydrides.

These related compounds, which have the formulæ $[(PPh_3)_4PtH_2]^0$ and $[(PPh_3)_3PtH_2]^0$, where PPh_3 is triphenylphosphine, were first prepared by Malatesta and Cariello[2a]. In the absence of evidence for the presence of metal-hydrogen bonds, they were originally formulated as tertiary phosphine complexes of zero-valent platinum. We have now shown that a third derivative $[(Ph_3P)_2PtH_2]^0$ (see ref. 2*b*) can be isolated from a benzene solution of either of the above hydrides, the other product of dissociation being triphenylphosphine. The compound $[(\text{diarsine})_2\text{-}PtCl_2]^0$, where diarsine has the formula I



(I)

has been prepared by treating $[(Ph_3P)_4PtH_2]^0$ with two moles of the diarsine in methylene chloride solution, the intermediate diarsine hydride reacting rapidly with the solvent. The properties of the various complex hydrides are given in Table 1.

The *tetrakis*-triphenylphosphine complex was prepared[2] by adding an aqueous solution of potassium tetra-chloroplatinate(II) to a solution of triphenyl-

Table 1. TYPICAL ANALYTICAL DATA

Compound	Colour	Melting point (° C.)	Calculated	Molecular weights In benzene	In nitrobenzene	In methylene chloride
$(PPh_3)_4PtH_2$	Ivory-yellow	116–118	1,242	400	915	—
$(PPh_3)_3PtH_2$	Yellow	125–130	982	420	800	—
$(PPh_3)_2PtH_2$*	Yellow-white	175–178	724	—	—	644

* Found: C, 60·8; H, 5·02 per cent; calculated for $C_{36}H_{32}P_2Pt$: C, 59·6; H, 4·4 per cent. Infra-red bands at 1,670 and 815 cm.$^{-1}$.

phosphine in alcohol containing potassium hydroxide. The reaction appears to be:

$$[PtCl_4]^{2-} + 2OH^- + 2C_2H_5OH + 4PPh_3 \rightarrow [(PPh_3)_4PtH_2]^0 + 2CH_3CHO + 4Cl^- + 2H_2O$$

The *tris*-triphenylphosphine complex was prepared[2] conveniently by adding hydrazine to a suspension of $[(Ph_3P)_2PtI_2]^0$ in ethanol.

The molecular weight in benzene found for the *tetrakis*- and *tris*-triphenylphosphine complexes may be interpreted in terms of a step-wise dissociation, namely:

$$[(PPh_3)_4PtH_2] \rightleftarrows [(PPh_3)_3PtH_2] + PPh_3$$
$$[(PPh_3)_3PtH_2] \rightleftarrows [(PPh_3)_2PtH_2] + PPh_3$$

The molecular weight in benzene indicates complete dissociation of both the *tetrakis*- and *tris*-compounds. This marked dissociation may, as suggested by Malatesta and Cariello[2], be due to some interaction of the complex with the solvent. This seems to be supported by the fact that the molecular weights in benzene are dependent on time; also, the benzene solutions show new infra-red bands which are not attributable to the solvent, the ligand or the complexes already mentioned. The dissociation is clearly much less in nitrobenzene (see Table 1).

The infra-red spectra have been studied, and some platinum–hydrogen active frequencies are shown in Table 1. As in other metal hydrides[3], the bands are characteristic of the metal-hydrogen stretching in regard both to frequency and shape. It is of interest to note that no Pt—H stretching frequencies in the usual region have been observed for the compounds $[(PPh_3)_4PtH_2]^0$ or $[(PPh_3)_3PtH_2]^0$. This is confirmed by deuteration studies. In contrast, however, the deuterium analogue of $[(PPh_3)_2PtH_2]^0$, prepared from a deuterated sample of $[(PPh_3)_3PtH_2]^0$, does show the presence of a Pt—D stretching frequency.

The number of hydride ligands in the *tetrakis*- and *tris*-compounds was determined by studying spectrophotometrically the amount of bromine consumed by these compounds. Known amounts of the solid complex were added to a standard solution of bromine in methylene chloride, and the disappearance of bromine studied by observing the absorption at 500 mμ. In both cases a sharp end-point occurred after 2 moles of bromine had been added; extraction of the resulting solution with water and titration of this with alkali revealed that 2 equivalents of hydrogen bromide had been produced:

$$[(PPh_3)_3 \text{ or } {}_4PtH_2]^0 + 2Br_2 \rightarrow [(PPh_3)_2PtBr_2]^0 + 2HBr + 1 \text{ or } 2\ PPh_3$$

The infra-red spectrum of the $[(PPh_3)_2PtBr_2]^0$ produced shows no Pt—H bands.

Further evidence for a Pt—H bond in the *tetrakis*- and *tris*-complexes is also provided by the vigorous reaction which they undergo with carbon tetrachloride to yield chloroform—a reaction which is characteristic of metal hydrides[3]. The composition of the products was established by vapour phase chromatography.

The fact that these triphenylphosphine adducts are considered to be hydrides of bivalent platinum raises the interesting question of whether any truly zerovalent complexes of platinum have yet been prepared; especially as the above hydrides have often been used as the intermediates in the preparation of certain Pt^0 compounds.

Thus, in the above compounds, in which the platinum atom is regarded as bivalent with a d^8 non-bonding configuration, we have examples of the metal atom with co-ordination numbers of 4 (cf. $[PtCl_4]^{2-}$), 5 (cf. $[Pt(\text{diarsine})_2Br]ClO_4$[5]) and 6 (cf. $[Pt(\text{triarsine})_2][ClO_4]_2$[6], $[Au(\text{diarsine})_2I_2]ClO_4$[7]).

We thank Dr. G. K. N. Reddy and Mr. K. Khaleeluddin for their assistance. One of us (J. A. C.) gratefully acknowledges the award of a Fulbright fellowship, during the tenure of which this work was carried out.

A Sealed-edge Theory of Graphite 'Compounds'

IN the stepwise formation and decomposition of certain graphite compounds, notably the bisulphate and the potassium compounds, surprise has often been expressed that one layer of carbon atoms can influence the behaviour of other layers that are several times the spacing of 3·35 Å. away.

The following tentative theory explains this by centering attention on the carbon atoms at the edges of the layers. It is generally agreed that these edge atoms are bonded to oxygen, hydrogen, hydroxyl or hydrocarbon residues and perhaps to similar atoms in adjacent layers. Now if such bonds between edge atoms do exist, either directly or through oxygen or hydrocarbon residues, then it is reasonable that not all of them from a given layer are directed to the same adjacent layer. Openings will therefore be available through which adducts can diffuse into the central volume, the sheathing layers of which are thereby forced out to two or three times their normal separation. If, however, the edge atom separations throughout the crystal are unaffected, the displaced layers will decrease the spacing to the next layers and may transmit the effect to several successive layers. This contraction is probably most significant near the edges, and indeed need be significant only there to influence diffusion to the central region. If great enough, it will prevent the occupation of one or more layers adjacent to a filled one. The theory therefore explains the non-filling of blocks of spaces in the formation of the compound and the emptying of blocks of spaces during decomposition. Various isotherms, kinetic studies, and other data will shortly be published to support the theory.

Field-Emission Microscopic Investigation of Catalysed Synthesis of Ammonia on Tungsten

Field-emission microscopy was applied to the investigation of the mechanism of the catalysed synthesis of ammonia on tungsten. It was concluded from the result that (1) the dissociative adsorption of nitrogen is considerably accelerated by the presence of hydrogen, and that (2) the rate-determining step of the synthesis is either the formation of adsorbed imino-group NH(a) from adsorbed nitrogen atom N(a) and hydrogen atom H(a), or that of adsorbed amino-group NH_2(a) from NH(a) and H(a) but not the dissociative adsorption of nitrogen, as is generally accepted.

Nitrogen, hydrogen, a 1 : 5 mixture of nitrogen and hydrogen, and ammonia were allowed, in turn, to be adsorbed on the clean tungsten tip of a field-emission microscope, while pressure was increased gradually from 10^{-9} to 10^{-7} mm. mercury and then decreased by evacuation. After evacuation was begun, the tip was subjected to intermittent heat treatments at temperatures raised successively from 500° to 3,000° K. Field-emission patterns and the associated changes of average work function were observed at liquid-nitrogen temperature for each series of gases along with the initial increase followed by decrease of pressure as well as after every heat treatment.

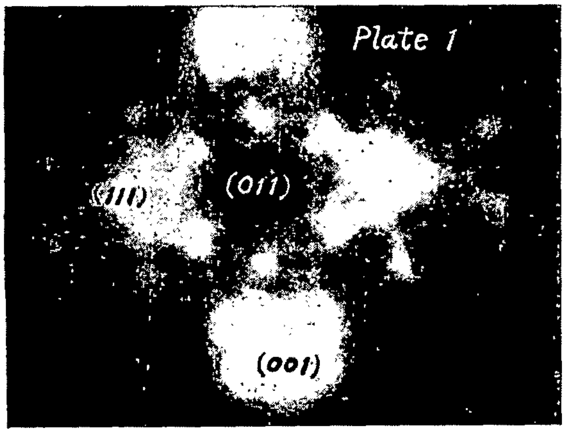

Fig. 1. The N(a) pattern has characteristics of the bright surroundings of the (001)-region and of the bright (111)-region. The increase of average work function $e\Delta\varphi$ is about 0·35 eV. from the initial value of the clean tungsten surface

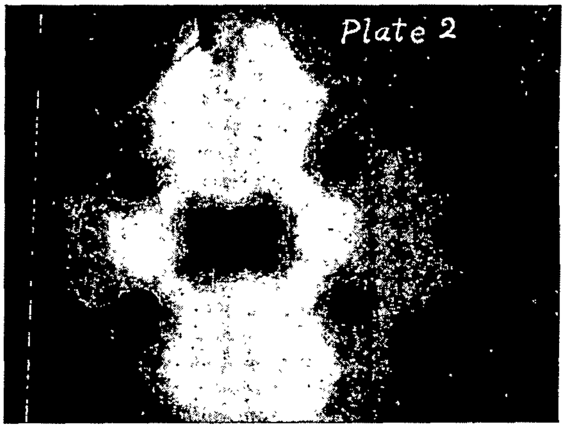

Fig. 2. The characteristics of the H(a) pattern are shown by the bright region spread toward the centre of the dark (011)-region along the (111)-(011) zone and the relatively darker (111)-region along the zone. $e\Delta\varphi$ is about 0·05 eV.

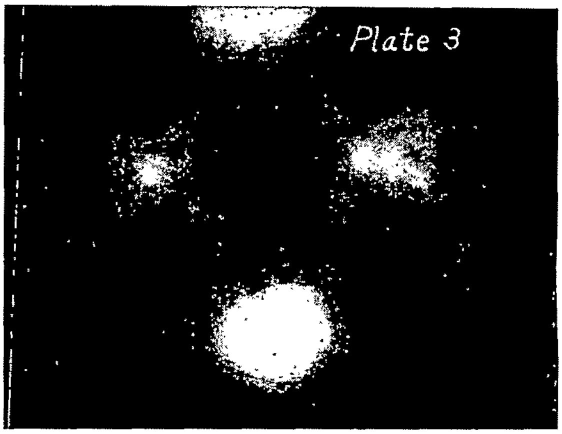

Fig. 3. The pattern of the nitrogen–hydrogen mixture is the superposition of the N(a) and H(a) patterns. $e\Delta\varphi$ is about 0·5 eV.

Figs. 1 and 2 show the patterns observed steadily at the later stage of the nitrogen and the hydrogen series. These patterns, along with associated changes of the average work function, were judged to be characteristic of N(a) and H(a). Fig. 3 is a pattern observed for a nitrogen–hydrogen mixture, which is identified as a superposition of the N(a) and H(a) patterns. Conclusion (1) was arrived at from the early appearance of a N(a) pattern in the latter series as compared with that in the nitrogen series. Fig. 4 for ammonia gives a pattern which is distinguishable from the patterns characteristic of N(a) and of H(a). The latter characteristic was attributed to NH(a) and/or NH_2(a) in agreement with an associated decrease of average work function.

The characteristic pattern of N(a) was observed with ammonia, just after the heat treatments at elevated temperatures. Similarly, patterns characteristic of NH(a) and/or NH_2(a) were observed with a nitrogen–hydrogen mixture after the heat treatments at elevated temperatures, but they were unstable.

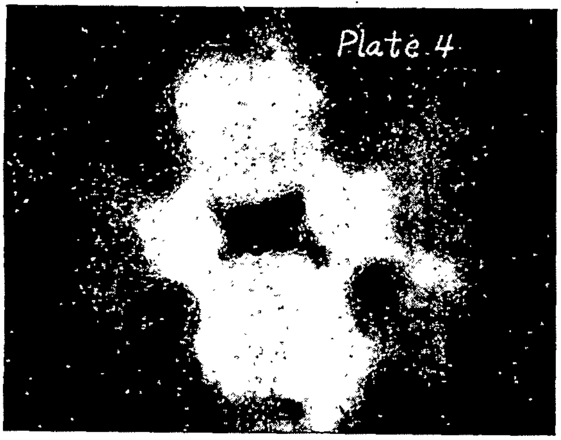

Fig. 4. The pattern of ammonia has the characteristically bright and dark regions along the (001)–(011) zone. $e\Delta\varphi$ is about −0·1 eV.

These results indicate that N(a) on one hand and NH(a) and/or NH_2(a) on the other hand are walled off from each other by a slow step, which is just surmounted in either direction by the later heat treatments; hence the conclusion (2) is arrived at, suggesting that catalysed ammonia synthesis proceeds through the sequence of steps: $N_2 \rightarrow 2N(a)$, $H_2 \rightarrow 2H(a)$, $N(a) + H(a) \rightarrow NH(a)$, $NH(a) + H(a) \rightarrow NH_2(a)$ and $NH_2(a) + H(a) \rightarrow NH_3$.

Detection of Trace Quantities of Acenaphthene by Gas Chromatography

In the course of investigations into the c-mitotic effect we wished to determine the acenaphthene uptake in the root tips of onions grown in a saturated water solution of acenaphthene. As the quantities expected were of the order of μ, the very sensitive flame ionization detector described by McWilliam and Dewar[1] was used. A 6-in. long ⅛-in. bore column packed with 60–80 mesh brick dust carrying 15 per cent w/w silicone oil was used for the analysis, and pure hydrogen was used as the carrier gas.

Because of the small amounts of material being handled it was necessary to introduce the samples on to the column in a solvent. For this purpose it was found that redistilled commercial 'Decalin' (b.p. 184–187° C.) was suitable. At the temperature of the column (183° C.) the main peaks of the 'Decalin' had been eluted before the appearance of the acenaphthene peak, and, although the sample used 'tailed' badly, the tailing was not sufficiently serious to interfere badly with the detection of acenaphthene.

More volatile solvents or solvent mixtures had, of course, very short retention times, and tended to give a sooty flame which interfered with the operation of the detector.

Tests with prepared solutions showed that we could detect quantities as small as 0·2 μgm. acenaphthene.

Onion roots were treated with ether and the extract, after evaporation to dryness at room temperature, was redissolved in 0·25 ml. decalin. 20-μl. samples of decalin solution were injected on to the head of the column. The detector sensitivity was turned down to minimum until the main decalin peaks had been eluted and was then increased until the 'noise-level' was about 2 per cent of full scale.

Chromatograms made with extract from onions grown in pure water showed no peaks in the region about the retention time of acenaphthene. The extract from onions grown in acenaphthene solution and showing c-mitotic activity gave peaks which on comparison with the test chromatograms correspond to about 5 μgm. acenaphthene (that is, about 60 μgm./gm. of root tip).

An attempt was made to determine the solubility of acenaphthene in water. 10 ml. of saturated solution was evaporated to dryness and any residue dissolved in 0·25 ml. decalin. No trace of acenaphthene was found in this solution. The solubility of acenaphthene is therefore less than 250 μgm./l. These results suggest a considerable uptake of acenaphthene in the root tips, the significance of which will be discussed in a later paper in conjunction with other experiments on the c-mitotic effect.

We wish to thank Mr. A. Adam for his invaluable assistance with the design and construction of the electronic equipment.

Polypeptide Formation from Asparagine under Hypothetically Primitive Conditions

This is a report of the formation of polyaspartic acid from asparagine[1] in aqueous solution under conditions which satisfy suggested primitive terrestrial conditions[2] better than thermal polycondensation[3,4].

When an aqueous solution of L-asparagine (5–10 per cent) was refluxed for several days, a part of the asparagine hydrolysed to aspartic acid; the other somewhat larger part formed a non-crystalline product[5]. This non-crystalline product was a mixture of aspartyl oligo- and poly-peptides which were separated as either water-insoluble Cu(II) or Pb(II) salts. Lyophilization of the solution of the free peptides, obtained with hydrogen sulphide from the salt, gave a white material. The yield was 62 per cent. When the polymerization of asparagine was carried out at 70–75° instead of 100°, the yield was 18 per cent. Van Slyke amino-nitrogen determination and dinitrophenol end-group analysis indicated average molecular weights between 380 and 530, corresponding to 3·3 and 4·4 units per molecule. Paper chromatogram (butanol–water or phenol–water) demonstrated the presence of a series of aspartic acid peptides, polypeptides and some aspartic acid. β-Aspartylaspartic acid was identified as being one of the oligopeptides present by comparison of the R_F value with that of an authentic sample[6].

Polyaspartic acid of higher molecular weight was obtained by dialysis of the original solution or of the crude polypeptide mixture. The average molecular weight of various preparations ranged from 1,700 to 3,000 (15–26 units) as determined by Van Slyke and dinitrophenol methods. Like α,β-polyaspartic acid[4], this polypeptide was highly soluble in water and gave a positive biuret reaction. The infra-red absorption spectrum was identical with that of polyaspartic acid[4c] (bands: NH stretching near 3μ; CO of carboxyl group 5·85μ; amide I 6·05μ; amide II 6·55μ) confirming the polypeptide structure. It is reasonable to assume that the polymerization of asparagine involves an intermolecular non-enzymatic transamidation reaction.

BIOCHEMISTRY

Enzymatic Formation of Histamine Ribotide from Histamine Dinucleotide

Alivisatos *et al.*[1,2] reported the formation of histamine dinucleotide, that is, the pyrophosphate of histamine 5′-ribotide and of 5′-adenylic acid, from diphosphopyridine nucleotide (DPN) and histamine, using a soluble, purified preparation of diphosphopyridine nucleotidase[3] (DPNase) from bovine spleen. It has been shown that nicotinamide[4,5] inhibits the release of histamine by antigen from the lung tissue of a sensitized guinea pig. Nicotinamide is a known inhibitor of DPNase and nicotinamide ribosidase[6]. These facts suggest the possibility that part of the histamine released during the antigen–antibody reaction is formed from histamine dinucleotide.

The present report describes some properties of histamine dinucleotide and of histamine ribotide. These compounds were recently isolated as pure preparations in the course of work which was concerned with the biological significance of histamine dinucleotide and related compounds, and with the formation of free histamine from such compounds. The formation of histamine ribotide had hitherto been reported only qualitatively by paper chromatographic and electrophoretic results[2].

$$\text{DPN} + \text{histamine} \xrightarrow[\text{bovine spleen or pig brain}]{\text{DPNase from}} \text{histamine dinucleotide} + \text{nicotinamide} + \text{H}^+ \quad (1)$$

The reaction (1) proceeded easily with DPN and histamine (2-^{14}C) as substrates, and with the use of insoluble, partially purified DPNase[7] from bovine spleen or pig brain. The reaction product, histamine dinucleotide, was found to be present in the fraction eluted from a column of 'Dowex-1' (*X*10, chloride form) by 0·002 *N* hydrochloric acid (*p*H 2·9). The dinucleotide, recrystallized from acetone-water mixture after lyophilization, did not lower the blood pressure of a cat and did not contract the ileum of a guinea pig *in vitro*. The dinucleotide was easily hydrolysed when heated with 2·5 *N* hydrochloric acid in a sealed tube at 150° C. for 5 hr. The free histamine was identified by its action on the cat's blood pressure and the guinea pig's ileum.

$$\text{Histamine dinucleotide} \xrightarrow[\text{diesterase}]{\text{phospho-}} \text{histamine ribotide} + \text{AMP} \quad (2)$$

100 mgm. of histamine (2-^{14}C) dinucleotide (purity, 88 per cent; specific activity, 1,419 c.p.m./μmole), obtained by the reaction (1), was incubated at 37° C. for 5 hr. in the presence of phosphodiesterase[8], purified from snake venom. Chromatography of the reaction mixture through a column of 'Dowex-1' (*X*10, chloride form) gave a radioactive fraction of histamine ribotide, having no absorption at 260 mμ, by elution with 0·001 *N* hydrochloric acid (*p*H 3·1) (Fig. 1). Fig. 1 also shows a substance having absorption at 260 mμ, obtained by elution with 0·004 *N* hydrochloric acid (*p*H 2·4). This substance was identified as 5′-adenylic acid (AMP) by paper chromatography.

The fraction containing histamine ribotide was first lyophilized and recrystallized from acetone–water mixture to 25 mgm. (yield, 58 per cent) of the crystals, m.p. 176–180° C. (decomp.), of this substance. The specific activity of this sample, calculated from the formula of the ribotide as $C_{10}H_{18}O_7N_3P \cdot HCl$ (359·5), gave 1,466 c.p.m./μmole, which agrees with that of the original dinucleotide. The ultra-violet spectrum of the dinucleotide exhibits absorption maxima at around 210 mμ and at 258 mμ, and that of ribotide at around 210 mμ. Both were positive to the ninhydrin and phosphate reactions. The R_F values on a paper chromatogram, using 0·1 *M* acetic acid/ethanol (1 : 1) mixture as a solvent, was 0·45 for the dinucleotide and 0·58 for the ribotide. The observed values for ribose per 1 μmole of the compound were 1·80 (calc., 2·00) for the dinucleotide and 0·96 (calc., 1·00) for the ribotide by periodate consumption, but were 0·86 for the dinucleotide and 0 for the ribotide by the orcinol reaction. The lower values of ribose by the latter method are considered to be due to the stability of the N—C

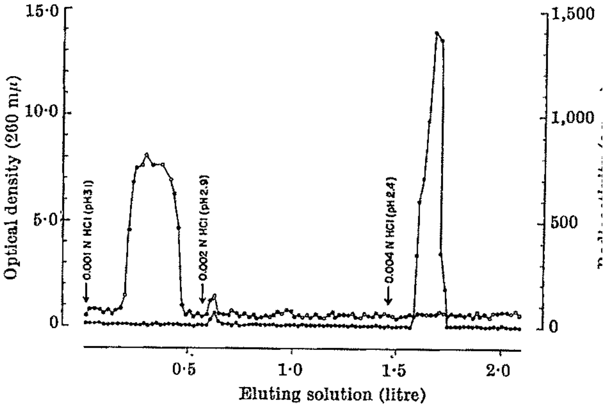

Fig. 1. Separation of histamine ribotide and adenylic acid by 'Dowex-1' (*X*10) in a chloride system. Fractions of 10 ml. were collected, and the radioactivity (○) and the optical density at 260 mμ (●) of each fraction were measured

bond between the imidazole and ribose in both substances[9]. However, this N—C bond is cleaved by decomposition with hydrochloric acid under a high pressure, liberating biologically active histamine in 40–83 per cent yield and inorganic phosphate in a yield close to 100 per cent of the theoretical value. The diazo reaction using sulphanilic acid on a paper chromatogram appears orange coloured in the dinucleotide and yellow in the ribotide. The absorption spectrum of the reaction solution, however, lacks the peak at 530 mμ characteristic of histamine in both substances, and a peak, assumed to be that of an azo compound, is observed at 380 mμ.

Histamine ribotide contracted the ileum of a guinea pig, but this action differed from that of histamine in that the contraction occurred gradually and was not inhibited by an antihistamine ('Neoantergan').

Inhibition of Chymotrypsin with Di*Iso*propyl Phosphorofluoridate

In a recent article Stein and Laidler[1] described the inhibition of chymotrypsin by di*iso*propyl phosphorofluoridate (DFP). They found that even when the inhibitor-enzyme ratio was as high as 4 : 1 no complete inhibition was observed. This was contrary to the results of Jansen *et al.*[2], who found that when the molar ratio of DFP to enzyme was more than unity, there was practically 100 per cent inhibition.

Stein and Laidler concluded from their results that under their conditions the interaction between DFP and chymotrypsin is reversible. Further evidence of the reversibility was derived from the results of experiments where the enzyme was added to a mixture of DFP and substrate (methyl hydrocinnamate). They found that the greater the substrate : inhibitor ratio the less was the falling-off of the substrate-splitting rate as the reaction proceeded.

The discrepancy between these results and those of Jansen *et al.* was attributed to a small amount of propanol in the reaction medium of the latter.

In a rather comprehensive study on the relationship between structure of organophosphorus compounds and their ability to inhibit esterases and related enzymes[10] I also studied the inhibition of chymotrypsin by DFP.

The inhibition reaction was carried out at 25·0° C. and at *p*H 7·7 either in 0·1 *M* phosphate buffer or in 0·0033 *M* sodium veronal buffer. At intervals, samples were withdrawn and the remaining enzyme activity was measured either by Anson's hæmoglobin digestion method[3] or by measuring the rate of hydrolysis of L-tyrosine ethyl ester at a substrate concentration of 0·025 *M*[4]. In carrying out these activity measurements, the inhibitor-enzyme mixture was diluted about 10 times.

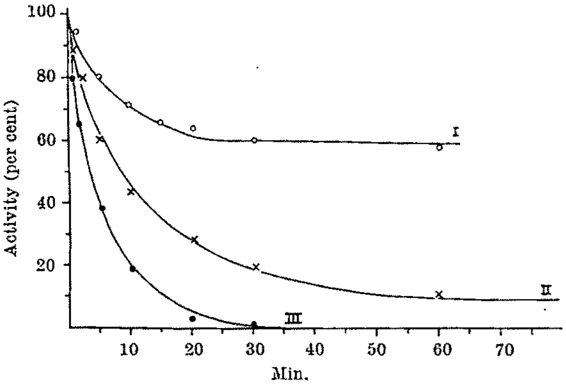

Fig. 1. Inhibition of chymotrypsin by DFP. Concentration of enzyme: $6 \cdot 6 \times 10^{-6}$ *M*. ○, Concentration of DFP, $2 \cdot 76 \times 10^{-6}$ *M*; ×, $6 \cdot 45 \times 10^{-6}$ *M*; ●, $1 \cdot 29 \times 10^{-5}$ *M*. All inhibition reactions carried out at *p*H 7·7 and 25° C.

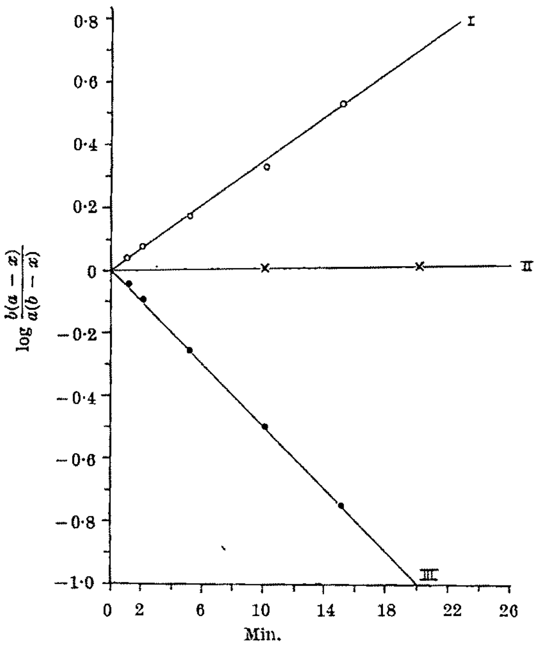

Fig. 2. The rate of inhibition of chymotrypsin by DFP. Concentration of DFP and enzyme the same as in Fig. 1

I was able to demonstrate that under my conditions the inhibition reaction was virtually stopped.

I found that the proteolytic activity is inhibited at the same rate as the esteratic activity, a result which is in agreement with the results of Jansen *et al.*[2] and Hartley and Kilby[5].

Figs. 1 and 2 give the results of three typical runs. From these kinetic data I calculated the bimolecular rate constant for the inhibition reaction. This has been done for the reaction of chymotrypsin with paraoxon by Hartley and Kilby[5]. In their case, however, pseudo first-order kinetics could be used, for a very large excess of paraoxon is needed in order to get proper enzyme inhibition within reasonable time. The authors remarked, however, that DFP inhibits chymotrypsin in such low concentration that the enzyme and inhibitor must be present in about equimolecular amounts.

That this is the case appears from a comparison of the concentrations of DFP used in the experiments of Fig. 1 and the enzyme concentration used, the latter being $6 \cdot 6 \times 10^{-6} M$. In these circumstances the second-order kinetics calculation has to be used. The well-known formula for the rate constant is:

$$k = \frac{1}{t} \times \frac{1}{a-b} \ln \frac{b(a-x)}{a(b-x)} \qquad (1)$$

a and b being the initial concentrations of enzyme and inhibitor respectively and x the concentration reacting in time t. In Fig. 2 $\log \frac{b(a-x)}{a(b-x)}$ is shown in relation to t. Straight lines are obtained; the slopes of these lines give the bimolecular rate constant. It was found that under our conditions:

$$k = 1 \cdot 9 \times 10^4 \text{ l.mol.}^{-1}\text{min.}^{-1}$$

This value corresponds very well with a value published by Jandorf *et al.* ($2 \cdot 0 \times 10^4$) without experimental conditions given, however[6].

The influence of the buffer appeared to be only slight, the value in the veronal buffer being $1 \cdot 7 \times 10^4$ l.mol.$^{-1}$min.$^{-1}$.

The results of Stein and Laidler, given in their Table 2, are obtained at 20·0° C. Unfortunately the *p*H value at which their experiments were carried out is given only as between 7·5 and 8·7. As the influence of the temperature on the inhibition reactions is not very great (I observed apparent activation energy of the order of 10 kcal./mol.) I have assumed that the above-mentioned rate constant is a good approximation of the rate constant under the conditions as given by Stein and Laidler. Using the concentrations of enzyme and DFP as given by Stein and Laidler, I calculated with the above-mentioned rate constant the amount of enzyme inhibition obtained with a reaction time of 10 min., assuming an ordinary bimolecular irreversible reaction and using formula (1).

The results are shown in Table 1, together with the experimentally obtained inhibition values of Stein and Laidler.

When Stein's values are compared with my calculated values striking similarity is seen, especially with the lower DFP concentrations. The fact that with the higher concentrations of DFP the measured inhibition is higher than the calculated values can be explained by the fact, observed by Stein and Laidler, that the addition of substrate (methyl hydrocinnamate) does not stop the inhibition reaction. The results of Stein and Laidler can thus be explained without the assumption of a reversible reaction.

Table 1. RESULTS OF STEIN AND LAIDLER (REF. 1) COMPARED WITH CALCULATED RESULTS FROM MY EXPERIMENTS. $[E]_0 = 3 \cdot 03 \times 10^{-6} M$

DFP × 10^6	DFP/$[E]_0$	Percentage of inhibition found by Stein and Laidler	Percentage of inhibition calculated with second order kinetics
1·18	0·39	17·0	16·0
2·36	0·78	28·6	29·5
3·54	1·17	45·1	40·5
4·72	1·56	48·0	51·5
5·36	1·77	61·8	56·5
8·04	2·65	83·2	72·0
10·72	3·54	87·8	82·5

The results with the mixtures of DFP and substrate are certainly not in contradiction of an irreversible bimolecular second-order inhibition reaction.

Concerning the discrepancy between the results of Stein and Laidler[1] and of Jansen *et al.*[2], I calculated the concentration of enzyme used by the latter authors. Assuming a nitrogen content of 15·83 per cent[7] and a molecular weight of 23,000 [8,9] I found that with 0·060 mgm. protein N/ml., the concentration is $1 \cdot 65 \times 10^{-5} M$. The reaction conditions of Jansen *et al.* are 25·0° C., 0·2 *M* phosphate buffer *p*H 7·7 and 20 min. reaction-time. With an equimolecular amount of DFP, and again assuming the rate constant $1 \cdot 9 \times 10^4$ l.mol.$^{-1}$min.$^{-1}$, I calculated an inhibition of 86·5 per cent, which is certainly much higher than the results of Stein and Laidler. As the concentrations used by Jansen *et al.* are higher and their reaction time longer, the result is not surprising.

Ammonia Dehydrogenase, Hydroxylamine Dehydrogenase, Hyponitrite Dehydrogenase and Nitrite Dehydrogenase

IT has previously[1,2] been reported that there is an enzymatic cycle of inorganic nitrogen. In the present work, we have demonstrated that the dehydrogenating system in the cyclic processes can be separated from the reducing one, and that each dehydrogenase behaves specifically towards different inhibitors. Moreover, the intermediates in the dehydrogenation have been determined quantitatively.

To fractionate enzymes, an acetone preparation was first made from fresh cockerel liver as described in refs. 1 and 2. The precipitate obtained with 33–55 per cent acetone was dissolved in cold water and mixed with 20–30 parts by volume hydroxyapatite as described by Tiselius, Hyertén and Levin[3]. After 1 hr. at 0° C., the suspension was centrifuged at 6,000 r.p.m. for 5 min. The sediment was washed twice with cooled water and extracted with a mixture of sodium acetate and acetic acid. The extract was dialysed against running water for 3 hr. and used as enzyme solution. Measurement of the action of dehydrogenase or reductase was as described in refs. 1 and 2. For comparing the enzyme activity, the value of $-\log T$ was divided by mgm. of protein nitrogen in the reaction mixture. The results are summarized in Table 1.

Table 1. SEPARATION OF DEHYDROGENASES FROM REDUCTASES

Substrate	0·01–0·1 *M* acetate, *p*H 6·6 Dehydrogenase activity	Reductase activity	2–4 *M* acetate, *p*H 7·5 Dehydrogenase activity	Reductase activity
NH_4Cl	0	—	+1·174	—
NH_2OH	+0·038	−3·808	+0·743	−0·090
$Na_2N_2O_2$	0	−4·115	+1·026	−0·101
$NaNO_2$	0	−4·308	+1·166	−0·103
$NaNO_3$	—	−4·000	—	−0·106

The dehydrogenating system was mostly eluted with 2–4 *M* acetate mixture and the reducing one with 0·01–0·1 *M* acetate. Compared with the enzymatic activity of the recentrifuged supernatant from liver homogenate, the dehydrogenases were purified 50–350-fold by these treatments and the reductases 550–750-fold.

In the inhibition tests for the dehydrogenating enzymes, a dialysed 2–4 *M* acetate extract was mixed with *tris*-buffer and inhibitor, and after 20 min. at 30° C., the substrate was added. Some of the results obtained are given in Table 2.

Table 2. INHIBITOR SPECIFICITY OF DEHYDROGENASES

Inhibitor	Substrate, inhibition (per cent)			
	NH_4Cl	NH_2OH	$Na_2N_2O_2$	$NaNO_2$
Sodium azide, 5×10^{-3} *M*	50	100	0	10
Thiourea, 5×10^{-3} *M*	50	60	20	20
Uric acid, 5×10^{-4} *M*	100	45	85	70
8-Hydroxyquinoline, 5×10^{-4} *M*	100	37	90	0
p-Chloromercuribenzoic acid, 5×10^{-4} *M*	100	0	90	100

It was observed that the dehydrogenation for each substrate is specifically inhibited by certain compounds, indicating that the dehydrogenating system consists of 4 substances.

For estimating the intermediary products in the dehydrogenation process, a larger amount of enzyme and coenzyme, namely, 2 ml. of liver preparation obtained with 33–55 per cent acetone and 8 mgm. of diphosphopyridine nucleotide, were added to the reaction mixture. Ammonia and hydroxylamine were determined by the indophenol method and our modified colorimetry method[4] respectively. It was found that hyponitrite can be estimated by our alkali process[4] for oximes; this was confirmed by using a crystalline salt, $Na_2N_2O_2 \cdot 8H_2O$, prepared according to the description of Jones and Scott[5]. The quantity of nitrite or nitrate was measured by applying Griess's reagent or the 2,4-xylenol method of Buckett, Duffield and Milton[6]. To determine hyponitrite in the reaction mixture containing hydroxylamine, hyponitrite and nitrite, half the mixture was boiled for 5 min. and the other half mixed with 2 volumes of methanol, because boiling for 5 min. decomposes hyponitrite completely but has no influence on the estimation of hydroxylamine and nitrite. After centrifuging, the total amount of hydroxylamine, hyponitrite and nitrite in the mixture treated with methanol as well as that of hydroxylamine and nitrite in the boiled mixture was measured by our alkali process[4]. The results are given in Table 3.

Table 3. DETERMINATION OF DEHYDROGENATION PRODUCTS

Substrate	Amount disappeared (N in μgm.)	Amount produced (N in μgm.)			
		NH_2OH	N_2O_2	NO_2	NO_3
NH_4Cl	32·0	5·1	—	9·5	13·0
NH_2OH	31·8	—	12·6	7·0	8·8
$Na_2N_2O_2$	19·4	—	—	6·5	2·1
$NaNO_2$	20·7	—	—	—	17·5

For the determination of hyponitrite in the hydroxylamine-dehydrogenation, 3×10^{-4} *M* 8-hydroxyquinoline was added to the reaction mixture.

Our experiments have shown clearly that the dehydrogenation and reduction are carried out by different enzyme systems, and our earlier investigation[1] was the first demonstration of such a reducing system in animals. The cyclic oxido-reduction of inorganic nitrogen was also found in yeasts[2]. Klausmeier and Bard[7] reported that di- or triphosphopyridine nucleotide is hydrogenated by *Bacillus subtilis* in the presence of ammonium hydroxide. However, Roussos, Takahashi and Nason[8] proved later that the hydrogenation of pyridine-coenzymes by *B. subtilis* is to be attributed to some factors other than an enzyme specific to ammonium.

The nitrogen cycle formulated by us[1] has been confirmed by these experiments.

Preparation of Sheep Growth Hormone

EXISTING methods for the preparation of sheep growth hormone by low-temperature ethanol fractionation[1] or salt fractionation, combined with ion exchange chromatography[2], are lengthy and involve a large number of individual steps. The same criticism applies to existing methods for preparation of ox growth hormone[3,4].

During an investigation of the separation of sheep pituitary proteins on a column of diethylaminoethylcellulose (DEAE-cellulose) it was found that under certain conditions all the growth hormone present, in quite simple sheep pituitary gland extracts, passed through the column without adsorption, whereas almost all the other pituitary proteins were adsorbed. Whatman DEAE-cellulose powder (DE60), containing 1·2 milli-equivalents of base per gm. of dry powder, was used in all experiments.

Extracts were prepared by grinding frozen pituitary glands with solid carbon dioxide, and extracting the resultant powder with sodium borate buffer (ionic strength 0·025; *p*H 8·6) for 3 hr. at 4° C. In some experiments these extracts were applied directly to the DEAE-cellulose column. In others the ground glands were extracted with a similar buffer, but to which 0·25 *M* sodium chloride had been added and the extract so obtained dialysed and freeze-dried. The dried material was then dissolved in sodium borate buffer and applied to the column. Both these starting materials contained approximately 0·1 mgm. of growth hormone per mgm. of non-dialysable material, expressed as the equivalent amount of the standard ox growth hormone preparation, *N.I.H. B*2 (kindly supplied by the Endocrinology Study Section, National Institutes of Health, Bethesda). The unadsorbed fraction obtained from the column contained 0·6–0·8 mgm. of growth hormone per mgm. of non-dialysable material. This material in 5 per cent w/v concentration was dialysed against distilled water. The resultant precipitate was equal in potency to the *N.I.H. B*2 growth hormone and yielded the equivalent of 2·5 gm. of growth hormone per kgm. of fresh glands.

Starch-gel electrophoresis did not show the presence of any proteins other than growth hormone (unpublished observations), but the limits of contamination with other pituitary hormones, as determined by bioassay methods, has not yet been investigated.

This method for preparing growth hormone uses only very mild conditions and involves a minimum number of steps. It has been applied successfully to the preparation of growth hormone from quantities of fresh, whole glands, ranging from 7 gm. to 200 gm. and using columns containing 20 gm.–150 gm. of DEAE-cellulose. There appears to be no difficulty in extending the method to either smaller or larger quantities of starting material.

Acute Effect of Three Antibiotics on Diuresis in the Rat

ONE of the side effects limiting the use of some polymyxins is renal toxicity.

Sodium colistinmethanesulphonate, a new antibiotic with a spectrum of activity very similar to that of the polymyxins, but with much lower systemic toxicity[1], was investigated for its effects upon urinary volume output and was compared in this respect with two polymyxins.

The influence of the administration of each antibiotic upon diuresis was estimated by measuring, after treatment, the urinary output in ml./kgm./hr., 2 and 5 hr. after administration of a water load. This was done in groups of 20 male Wistar rats of approximately 360 gm. which were used twice consecutively in the following manner: first, the normal urinary volume output figures were determined for each group; 2 days later, the same procedure was repeated, each group receiving subcutaneously its respective antibiotic treatment at the same time as the intragastric water load. Each time the rats were starved (food and water) for 18 hr. before intragastric administration of a 50 ml./kgm. tap water load. The animals were then placed in metabolic cages without food and water and their urinary excretion was recorded at 2 and 5 hr., aggregated, and computed as indicated in Table 1.

The results at 2 and 5 hr. indicate that a very marked inhibition of diuresis occurred with all doses of either polymyxin *B* or colistin sulphate up to 1·67 mgm./kgm., whereas doses of sodium colistinmethanesulphonate up to 1·67 mgm./kgm. tended to increase diuresis. However, inhibition of diuresis was observed also with sodium colistinmethanesulphonate at doses above 1·67 mgm./kgm., but it was necessary to administer as much as 16·7 mgm./kgm. in order to obtain a degree of inhibition similar to that noted with 1·67 mgm. of the two other antibiotics. This indicates that, of the three antibiotics tested, sodium colistinmethanesulphonate interferes much less with urinary function, a fact that may explain its higher margin of safety.

Preparation and Properties of Purified House Dust Allergen

ALTHOUGH house dust allergens have been the subject of many investigations[1], attempts to establish the chemical identity of the specific house dust antigen thus far have met with very little success. This is partly due to the complex nature of crude house dust extracts, which, apart from non-specific toxic substances, contain many other allergens as well (derived from feathers, human and animal dandruff, etc.).

Boatner and Efron[2] were among the first to indicate the general protein nature of active preparations from house dust. Rimington *et al.*[3], in a more detailed study, obtained a purified dust fraction which was found to contain two electrophoretically distinct components of similar chemical composition and skin reactivity. The substance was found to give both protein and carbohydrate reactions. Recently, Vannier and Campbell[4] reported the isolation of a purified dust allergen which they estimated to contain 95 per cent carbohydrate and 5 per cent protein.

We wish to report the isolation of a purified house dust allergen with high activity in intradermal skin tests, the substance being apparently devoid of non-specific toxic substances and interfering allergens.

1,700 gm. of pooled house dust (collected during September–October, 1960) were extracted with a phosphate buffer $2 \cdot 8 \times 10^{-2}$ *M*, *p*H 7·0, containing $6 \cdot 5 \times 10^{-2}$ *M* sodium chloride and 0·5 per cent phenol. After two days at room temperature, the thick mud was squeezed and the resulting fluid filtered through a 0·5-cm. thick layer of kieselguhr. From the clear, deep-brown coloured filtrate the allergens were obtained by adsorption on benzoic acid at *p*H 4·00, using Sutherland's method[5]. The precipitated benzoic acid was filtered and dissolved in acetone, in which the allergens are insoluble. After washing once with ice-cold acetone, the crude mixture of allergens was extracted twice with the above-mentioned phosphate buffer, the undissolved residue being discarded.

The clear solution was then dialysed in a semi-permeable 'Cellophane' bag against running tap water, followed by dialysis against 0·01 *M* sodium ethylenediamine tetraacetate solution, *p*H 7·00, and distilled water successively. Further purification could be achieved by ammonium sulphate fractionation, the fraction precipitating between 25 and 100 per cent saturation being collected.

This brown-coloured product was dissolved in water and dialysed. The solution was then adjusted to *p*H 3·1 with hydrochloric acid. The resulting precipitate was separated by centrifugation after one day, dissolved in water and lyophilized. Clinical evidence suggests the identity of this product with the human dandruff allergen (Voorhorst[6]). The supernatant at *p*H 3·1 was treated with 4 volumes of acetone. A flocculent pink precipitate formed which was collected by centrifugation, dissolved in water and lyophilized. The yield was 35 mgm.

The substance thus obtained was very easily soluble in water and in physiological salt solutions. Markedly positive reactions were obtained with 2×10^{-5} mgm. (1 : 5,000,000) in intradermal skin tests with patients showing the typical symptoms of house dust allergy. Reagins against this substance could be demonstrated by means of Prausnitz-Küstner passive transfer tests. Controls were always found to be negative.

Paper chromatography of hydrolysates revealed the presence of 12 amino-acids: glu, asp, arg, lys, ser, val, thr, ala, pro, leu, *iso*leu, and cysteic acid. At least three carbohydrates could be detected: galactose, arabinose and xylose. The substance contains 7 per cent nitrogen (micro-Kjeldahl) and 42 per cent hexose (expressed as equivalent glucose in the orcinol test), which suggests it is a mucoprotein, possibly of plant origin. Preliminary ultracentrifugal analysis gave a sedimentation constant of 2·2, indicating a molecular weight of 22–25,000. Further purification was effected on columns of diethylaminoethyl cellulose.

It should be noted that precipitation of the allergen from saturated ammonium sulphate solutions is not complete; after complete saturation, the supernatant still contains about 7 per cent protein (1·4 per cent nitrogen), derived from unprecipitated allergen, as well as a mixture of polyuronides. A similar phenomenon has been reported in the case of trichophytin[7]. A detailed account of this work will be published elsewhere.

Our thanks are due to Prof. L. H. Jansen for his interest in this work.

A New Technique of Chromatography and Ionophoresis on Ion-exchange Paper: Application to the Separation of Barbiturate, Salicylate and Acetophenetidin

We have found that, when a mixture containing barbiturate, salicylate and acetophenetidin is subjected to chromatography on Whatman No. *DE*20 cellulosic ion-exchange paper in dilute ammonia solution, a partial resolution of the components is possible. Salicylate is clearly separated from the other two compounds, which move together with only partial resolution (Fig. 1).

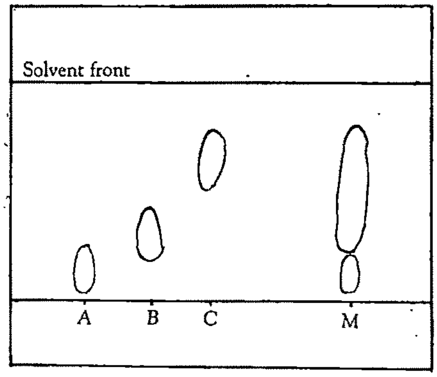

Fig. 1. Ascending chromatography on *DE*20 paper in 0·2 *N* ammonia. Time, 12 min. *A*, salicylate; *B*, phenobarbitone; *C*, acetophenetidin; *M*, mixture of *A*, *B* and *C*

However, if after chromatography the wet paper is subjected to ionophoresis (again in dilute ammonia solution) in a direction at right angles to the chromatographic solvent flow, a complete resolution of all three components of the mixture can be effected in

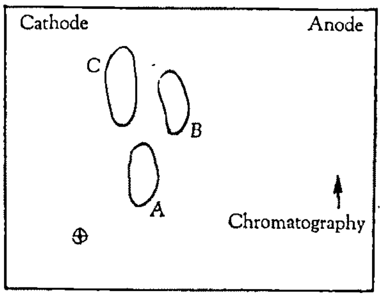

Fig. 2. Ascending chromatography on *DE*20 paper in 0·2 *N* ammonia, followed by ionophoresis for 30 min. in direction at right angles. *A*, *B* and *C*, as in Fig. 1. ⊕, Point of application

only 30 min. (Fig. 2). The chromatography takes only 10–12 min.

By using a micro-electrophoresis tank (Shandon Scientific Co., London), it is possible to carry out the chromatography and the ionophoresis in the same tank with the same solution.

It is interesting to note that when a mixture of salicylate and barbiturate is subjected to ionophoresis on 'ordinary' filter paper, the salicylate moves faster than the barbiturate[1], whereas the reverse is the case with *DE*20 paper. The technique of combining chromatography and ionophoresis on ion-exchange papers may lend itself to rapid separation of mixtures of amino-acids, of mixtures of acids of the Krebs cycle, and of many other mixtures of substances which are either not resolved satisfactorily on paper or which involve conventional chromatography for many hours.

Work is now in progress to develop this technique into a rapid screening test for barbiturates in blood. The technique is also being applied to the separation of alkaloids and other compounds of toxicological interest using different ion-exchange papers. The results of these experiments will be published elsewhere.

Destruction of Linoleate Hydroperoxide by Soya Extracts

WHEN Balls *et al.* used a thiocyanate assay to estimate oxidation of linoleate by soya lipoxidase, their results suggested that under certain conditions part of the linoleate hydroperoxide produced by the enzyme was afterwards destroyed by crude, but not by purified, enzyme preparations[1]. The reason for this has not been known, although Theorell *et al.* implied that spontaneous decomposition of hydroperoxide might be responsible[2]. Recent work has indicated that there is in crude extracts of soya a factor which destroys β-carotene in the presence of linoleate hydroperoxide[3]. Here, we have examined the possibility that such a factor may also destroy linoleate hydroperoxide enzymically in the absence of β-carotene.

Sumner's thiocyanate assay for peroxide, as modified by Koch *et al.*[4], was used, pure linoleic acid in alcohol solution being added as substrate to *p*H 6·5 phosphate–citrate buffer to give a concentration of 1·36 × 10^{-3} *M* in the reaction mixture. Centrifuged dialysed extracts of 1 gm. defatted soya bean meal in 100 ml. water were used as enzyme source, volumes of 0·1–3 ml. being added to 25 ml. of buffer-substrate.

It was found that with small additions of soya extract (0·1–0·5 ml.) there was proportionality of reaction-rate to added enzyme, but that with larger additions (1–3 ml.) hydroperoxide formation was followed by destruction. Results obtained with 2 ml. soya extract are shown in curve *A* in Fig. 1.

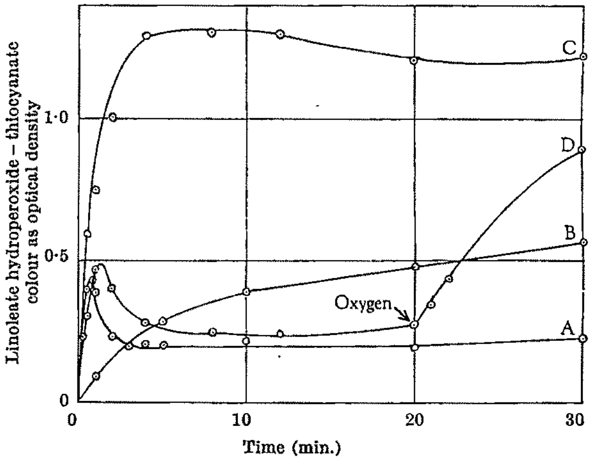

Fig. 1. Formation and destruction of linoleate hydroperoxide. *A*, 2 ml. soya extract ; *B*, 0·3 ml. soya extract; *C*, 2 ml. soya extract and oxygenated buffer; *D*, 2 ml. soya extract and oxygen passed in after 20 min.

Using only 0·3 ml. soya extract, hydroperoxide increase was initially less rapid, but no destruction was observed (curve *B*, Fig. 1) and formation continued steadily up to 80 min. But if a further 2 ml. soya extract were added to the same system at 40 min. from zero time, hydroperoxide destruction, of the same order as shown in curve *A*, resulted. Peroxide destruction did not occur if the 2 ml. soya extract were heated for 3 min. at 80° C. Similar results were obtained when extracts of defatted lentil and of defatted wheat germ (5 gm./100 ml. water) were examined in the same fashion.

These results suggest that the hydroperoxide-destroying factor is enzymic, since it is heat-labile and non-dialysing.

Maier and Tappel[5] have shown that hæmoglobin, acting as a catalyst for the decomposition of linoleate hydroperoxide, is only slightly less active than catalase, and much more active than peroxidase or cytochrome *c*. On the system which we have described, added hæmoglobin solution had to be at least 5 × 10^{-5} *M*, with respect to hæmatin, to destroy as much hydroperoxide as did an equal volume of soya extract. Our soya extracts do not contain enough total hæmatin to be observed spectrophotometrically as pyridine hæmochromogen under conditions where a concentration of 10^{-5} *M* would be obvious, and it may be inferred that if an iron porphyrin compound is responsible for peroxide destruction then its activity in this respect is much higher than those mentioned.

The sudden change from hydroperoxide formation to hydroperoxide destruction may be attributed to exhaustion of available oxygen, since it occurs at a point (Fig. 1) where hydroperoxide, measured as conjugated diene at 232 mμ (assuming an extinction coefficient of 28,000), is 2·3 × 10^{-4} *M*. The calculated molarity of dissolved oxygen in the system is about 3 × 10^{-4} *M*, which suggests that linoleate oxidation ceases because of lack of oxygen, to be succeeded by anaerobic peroxide destruction.

To verify this we repeated the experiment which gave curve *A* in Fig. 1 after first saturating the buffer with oxygen (curve *C*), and alternatively passing in oxygen after the fall in hydroperoxide had occurred (curve *D*). These results confirm the supposition.

It was observed in these experiments that, with small volumes of added soya (0·3 ml.), hydroperoxide formation, calculated from thiocyanate values, was proportional in the early stages to diene formation, but between 2 and 3 times greater. This accords with observations that thiocyanate methods give results between 2 and 3 times the theoretical[6]. We did not establish this proportionality with larger amounts of soya: with these, when destruction of peroxide occurred, there was no corresponding decrease of diene, suggesting that the products of hydroperoxide destruction remain conjugated. A full account of this work will be published elsewhere.

We thank the Department of Scientific and Industrial Research for financial support of this work.

Reduction of Coenzyme Q by Succinic Acid Dehydrogenase

It has been pointed out to us that our recent communication under this title[1] could be misunderstood as a claim of having first shown the insensitivity to antimycin A of reduction of ubiquinone. The credit of this observation belongs to Drs. A. M. Pumphrey and E. R. Redfearn[2]. The purpose of our communication was to show that this reduction could be obtained with a non-particulate soluble preparation, simpler than those which have mostly been used hitherto.

PHYSIOLOGY

Functional Interpretation of Cerebellar Histology

The nature of the transformation of patterns of excitation within the cerebellar cortex may be explained by the following argument, based mainly on histological evidence and on some simple physiological assumptions.

For all vertebrates studied the following facts emerge[1-5]: (*a*) The cerebellar cortex is a sheet of grey substance with anisotropic structure. Entirely different histological pictures are obtained in sections cut in frontal and sagittal planes. (*b*) All output fibres arise from one type of neurons (Purkinje cells) the dendritic fields of which are characteristically flattened in the laterolateral direction. (*c*) One set of input fibres (climbing fibres) is connected one-to-one with the set of Purkinje cells. (*d*) Another set of input fibres (mossy fibres) reaches the output (Purkinje) cells via long (about 5–10 mm.), very thin (about 0·2μ), unmyelinated fibres, the so-called parallel fibres, oriented exclusively in the laterolateral direction, each making the same kind of histological contacts with a long row of Purkinje cells (about 130 in the human cerebellum). Fig. 1 shows diagrammatically a fragment of such a laterolateral row with incoming and outgoing fibres.

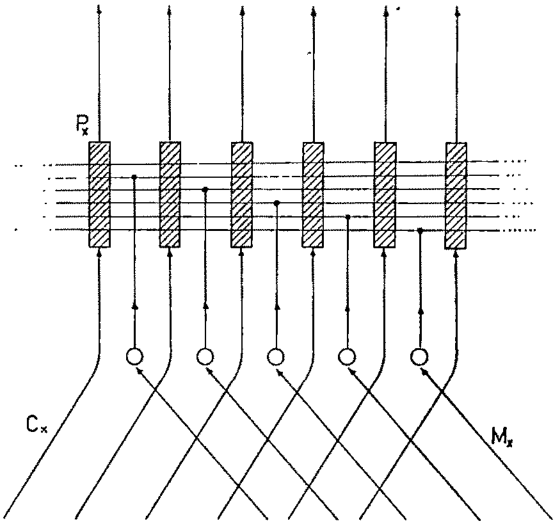

Fig. 1

It has been pointed out[5] that the organization of the cerebellar cortex as it appears in sections cut in the frontal plane becomes understandable if interpreted as a specialization for accurate timing of impulses.

Taking into account the well-known relation between diameter of fibres and velocity of conduction, and interpreting the histological connexion of climbing fibres–Purkinje cells as well as that of parallel fibres–Purkinje cells as an indication of synaptic connexions, this histology allows one to predict widely varying delays interposed between the input in one fibre system (the mossy fibres) and the arrival of activity at different laterolateral distances from the point of input, while, on the contrary, the other input system (the climbing fibres) should influence Purkinje cells after a fixed, short time delay.

Direct physiological support for this interpretation is provided in a paper by Calne[6], who found, in the frog, for some sites of stimulation a fixed delay between stimulus and response in the cerebellar cortex, and for other sites of stimulation delays varying between 20 and 260 msec.

Let $P_x(t)$, $M_x(t)$ and $C_x(t)$ be three sets of functions of time with common indices x. We may interpret them as representing activity in Purkinje cells, mossy fibres and climbing fibres of one laterolateral row, such as those in Fig. 1, with x representing the distance of the elements from an arbitrary origin. For convenience I assume all functions to assume only the values 1 and 0, and consider only integral values of x and t, since these simplifications do not significantly alter our argument. Neglecting the short, fixed synaptic delay between climbing fibres and Purkinje cells, our physiological hypothesis becomes:

$$P_{x_0}(t) = f\left[M_x\left(t - \frac{|x_0 - x|}{v}\right), C_{x_0}(t)\right]$$

where v represents the velocity of conduction in parallel fibres which we suppose to be constant. For a fixed value of C_{x_0}, $P_{x_0}(t) = f\left[M_x\left(t-\frac{|x_0-x|}{v}\right)\right]$, that is, simply a function of a linear combination of time and place of all $M_x(t) = 1$. Explicitly, we may assume the following dependence :

$$P_{x_0}(t) = 1 \text{ if} \left[\sum_x M_x\left(t-\frac{|x_0-x|}{v}\right) + C_{x_0}(t) - \Theta\right] > 0$$

and $P_{x_0}(t)=0$ otherwise, where Θ is a positive integer representing the threshold of Purkinje cells.

This can be used for transforming distances into time intervals and vice versa; in other words, as a clock. Among the many possible modes of operation which suggest themselves I mention only the following examples :

(*a*) Operation as an 'alarm clock'. If $M_{x_0}=1$ only at t_0 and $C_{x_0+\Delta x} = 1$ all the time while all other $C_x=0$, putting $\Theta=2$, there will be a $P_x=1$ only at $t_0 + \frac{\Delta x}{v}$.

(*b*) Operation as a 'stop watch'. $M_{x_0}=1$ only at t_0, all other $M_x=0$. All $C_x=1$ only at the unknown time t. There will be only one $P_x=1$ at t. The distance $|x-x_0|$ will furnish a measure of the unknown time interval $t-t_0$. Again we put $\Theta=2$.

(*c*) Operation as coincidence and time shift detector. Let $M_{x_1}(t)$ and $M_{x_2}(t)$ be two unknown functions. All other $M_x(t)=0$ and all $C_x(t)=0$. We can use $P_x(t)$ with $\Theta=2$ as coincidence detectors between $M_{x_1}(t)$ and $M_{x_2}(t)$. $P_{x_1+x_2/2}$ evaluates $M_{x_1}(t)+M_{x_2}(t)$. Other P_x evaluate the two functions shifted in time one with respect to the other, since :

$$P_x = f\left[M_{x_1}(t) + M_{x_2}\left(t - \frac{x_1 + x_2 - 2x}{v}\right)\right]$$

This embodies the principle of cross-correlation between the two functions, with logical product in place of algebraic product. If we sum each $P_x(t)$ over time, we obtain from one row a direct display of something analogous, in the discrete case, to a cross-correlation function of $M_{x_1}(t)$ and $M_{x_2}(t)$.

Function of Limb Tremor

THE collaboration of biologists and engineers has led to a hypothesis concerning the biological function of limb tremor in the frequency-range of 6–15 c./sec.

A target spot of light on a cathode ray tube was moved along a horizontal line into different positions at 1-sec. intervals. An operator was given the task of moving a joystick which controlled the movement of a 'follower' spot of light on the cathode ray tube, in the manner required to bring the 'follower spot' into line with the target spot as quickly and accurately as possible. The manually controlled servo-mechanism was a high-gain positional system with no delays in time between control and display movements.

Records of the target and joystick movements were taken on a high-speed pen recorder. Back-lash in the system set an arbitrary lower limit to the amplitude of limb movements which were recorded. Some observations incidental to the main experiment are reported here.

The records of six experimental subjects were analysed for evidence of a relationship between the limb tremor recorded in the range of 6–15 c./sec. and three different states of the subjects' 'controlling' limb : (*a*) at rest ; (*b*) while making the gross rapid movements of primary adjustment ; (*c*) while making the fine movements of secondary adjustment. It was found that 80 per cent of all tremor, of amplitude exceeding the measurement threshold, appeared while making the movements of precise secondary adjustment.

The finding reported agrees with much previous information[1] ; but a new hypothesis has been formulated concerning the function of the type of tremor described.

Mechanical servo-systems have been designed to maintain small oscillations of medium frequency, that is, the servo 'dither' effect because this 'dither' takes up back-lash in the system and minimizes the break-out forces required to overcome frictional resistances when movements are initiated. Peripheral mechanisms for controlling movement of body limbs (for example, muscle spindles, annulo-spiral nerve-endings and associated loops) bear close analogy to such mechanical servo-systems[2], and it is suggested that limb tremor provides the same advantages as 'servo dither'. The fact that tremor was most marked in the phase of the experiment which necessitated the greatest precision of movement lends support to the hypothesis presented.

The functional analogies which have been suggested between limb tremor and servo dither may be applicable to such similar fine tremor of the eyes and of the head in visual and auditory localization.

Increased Toxicity of Serotonin in Adrenalectomized Animals

ADRENALECTOMIZED rats and mice are more sensitive to anaphylactic shock[1,2], and to the action of histamine[3] and 5-hydroxytryptamine[2,4] which may be involved in the anaphylactic reaction[5], than are intact animals. The toxicity of histamine and of serotonin, as well as anaphylaxis, is increased by the administration of 'pertussis vaccine' and in old and tumour-bearing animals[6]. The present communication reports the toxicity of serotonin in rats and mice in some of these experimental conditions. Sprague–Dawley rats and *ALAL* mice (obtained from the firm ALAL, Milan), of an average weight shown in Table 1, were injected by different routes with 5 - hydroxytryptamine - creatinine - sulphate (kindly supplied by Vister Labs, Casatenovo, Como). Adrenalectomy was performed 72 hr. before injection ;

Table 1. TOXICITY OF SEROTONIN IN VARIOUS EXPERIMENTAL CONDITIONS

Species	No. of animals	Av. body-weight (gm.)	Experimental condition	Route of administration	LD_{50} (mgm./kgm.)	95 per cent confidence limits

,,	35	177	Adrenalectomized 72 hr. earlier (young)	i.v.	5·8	6·7–5·0
,,	27	397	Adrenalectomized 72 hr. earlier (old)	i.v.	1·2	1·7–0·9
,,	39	269	Walker carcinosarcoma	i.v.	46	61·2–34·5
,,	28	157	Partial hepatectomy 48 hr. earlier	i.v.	155	217·0–111·0
Mouse	60	10	Intact (young)	i.v.	245	303·8–197·5
,,	38	34	Intact (old)	i.v.	148	198·3–110·4
,,	56	19	Intact (adult)	i.v.	223	285·4–174·0
,,	20	19	Intact (adult)	i.p.	> 600	—
,,	20	19	Intact (adult)	s.c.	> 600	—
,,	67	18	Adrenalectomized 72 hr. earlier (adult)	i.v.	0·9	1·4–0·5
,,	87	19	Adrenalectomized 72 hr. earlier (adult)	i.p.	1·9	4·8–0·7
,,	45	18	Adrenalectomized 72 hr. earlier (adult)	s.c.	19	23·4–15·4
,,	45	21	Sarcoma 180 (adult)	i.v.	95	121·6–74·2

* Adrenalectomized animals were kept drinking saline.

partial hepatectomy—according to the method of Higgins and Anderson[7]—was carried out 48 hr. before, and Walker carcinosarcoma was implanted 15 days before.

The mortality, within 24 hr., was observed. The LD_{50} values in mgm./kgm. are expressed as 5-hydroxytryptamine–creatinine-sulphate, and confidence limits were calculated by Litchfield's method[8].

In rats a remarkable increase of serotonin toxicity is observed in older animals as compared with young ones. Adrenalectomy increases the toxicity of serotonin in both young and old animals, when given either by subcutaneous or intravenous routes of administration.

In other experiments, not reported in Table 1, it was observed that animals submitted to adrenalectomy 7 and 14 days before carrying out the test were even more sensitive to serotonin than animals adrenalectomized only 72 hr. before.

Partial hepatectomy has no effect on the toxicity of serotonin, and Walker tumour-bearing animals are relatively more sensitive than normal rats.

In mice, age is not such an important factor in serotonin toxicity as in the rat. Adrenalectomy is more effective in mice than in rats in sensitizing to serotonin toxicity. A factor of 29–36 represents the difference between intact and adrenalectomized rats, whereas in mice, when serotonin is given intravenously, this factor is 239. Mice bearing sarcoma 180 are also more sensitive than normal mice to serotonin.

The reasons for the increased sensitivity to serotonin of adrenalectomized animals are under investigation and will be reported elsewhere.

Some Properties of Rat Mammary Tissue

IN 1952 Cross and Harris[1] demonstrated that the degree of milk ejection in a lactating rabbit was dependent on the dose of intravenously injected posterior pituitary extract (pituitrin). A minimal effect was seen after injection of 5 mU. of pituitrin and 200 mU. gave a maximal response. On histological evidence, Richardson[2] had suggested that the myoepithelium was responsible for the expression of milk, and Linzell[3] was able to show that oxytocin caused this milk injection by contracting the myoepithelial tissue surrounding the alveoli. He showed further that acetylcholine, histamine and 5-hydroxytryptamine were all capable of causing such contraction when applied directly to lobules of the mammary glands of lactating mice. However, the milk-ejecting response could be made more specific for oxytocin by using atropine and dibenamine, the concentrations needed to block acetylcholine and histamine respectively having no effect on the response to oxytocin. The use of the milk-ejection response in lactating rabbits as an assay method for oxytocin has been described by van Dyke, Adamsons and Engel[4]. These workers could detect no changes in the intramammary pressure to intravenously injected histamine or 5-hydroxytryptamine, and showed that highly purified vasopressin had approximately 17 per cent of the milk-ejecting potency of pure oxytocin, the comparison being on a unit to unit basis. This was in agreement with work on lactating sows by Whittlestone (1955), but Linzell, comparing the two peptides by the amounts needed to produce threshold responses after topical application to mouse mammary lobules, found oxytocin to be even more potent. Highly purified vasopressin had only 8 per cent of the milk-ejecting potency of an equal unitage of pure oxytocin. This discrepancy might be explained as a species difference or by the different routes of administration used, the intravenous route allowing vasopressin to exert its vasoconstrictor action and so possibly enhance falsely the milk-injecting response. Méndez-Bauer, Cabot and Caldeyro Barcia[5] found that rabbit mammary strips in an organ bath gave graded increases in tension to doses of oxytocin and so it seemed worth while to compare vasopressin against oxytocin on rat mammary strips and, in addition, to investigate the usefulness of the rat mammary strip as an assay tissue for oxytocin. Méndez-Bauer, Cabot and Caldeyro Barcia[5] used sections of lactating

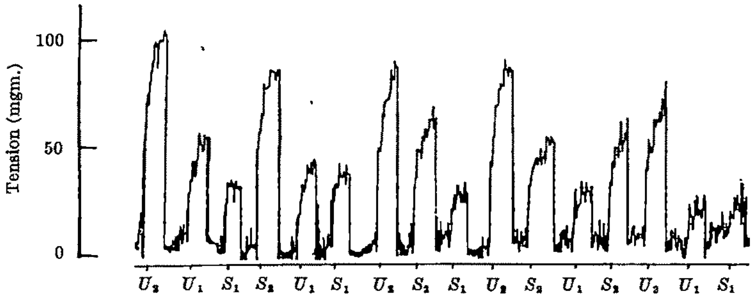

Fig. 1. Graded responses of rat mammary strip to varying doses of oxytocin: S_2, 8 mU.; S_1, 4 mU.; U_2, 10 mU.; U_1, 5 mU.

rabbit mammary glands taken from the nipple up to and including alveoli with associated myoepithelium. In view of the work of Linzell, the rat mammary strips used consisted only of alveoli with myoepithelium and a few small ducts, this tissue being dissected from the lower abdominal mammary glands of a lactating rat anæsthetized with urethane. The Ringer used was that of Edmunds and Cushny[6]; the arginine vasopressin used had been highly purified by the method of Sachs[7]. The oxytocin was supplied by Parke Davis and Co. ('Syntocinon').

To record differences in tension, the mammary strip, suspended in Ringer at a temperature of 37° C. in an organ bath (volume 10 ml.), was attached by a thread to an RCA transducer tube, No. 5734. The transducer acted as a variable resistance in a Wheatstone bridge arrangement. As tension in the muscle increased, the transducer nipple moved slightly, the resistance changed and the current flowing in the circuit was either measured directly on a sensitive micro-ammeter or recorded on paper after amplification. The current flow was directly proportional to the tension exerted on the transducer over the weight range 0–1,000 mgm., and all experimental work was within this tension range.

At the beginning of each experiment the strip was placed under an initial tension of 500 mgm. and the bridge balanced, using an adjustable resistance, so that no current flowed. Doses of oxytocin were then added at approximately 5-min. intervals, the Ringer being changed twice between each addition of oxytocin. Typical responses to four different doses of oxytocin are shown in Fig. 1. To determine the precision of the oxytocin assay, 4 doses, 2 high and 2 low, were chosen. Each dose was given once in any block of four, and one complete assay consisted of 16 responses. A high and low dose was arbitrarily selected as being the solution of 'unknown' concentration and the experimental potency ratio was calculated and compared with the known value. Table 1 shows the results of a series of five such assays.

Table 1. PRECISION OF RAT MAMMARY STRIP ASSAY METHOD FOR OXYTOCIN

R_t	R_c	E	R_1	R_2	Percentage of fiducial limits $P = 0·05$
1·25	1·26	0·8	1·114	1·434	± 12·7
1·25	1·09	12·8	0·910	1·285	± 17·1
1·25	1·22	3·0	1·100	1·355	± 10·5
1·25	1·25	0·2	1·016	1·542	± 21·0
1·25	1·22	3·0	1·052	1·422	± 15·2

E is the percentage difference between R_t, the theoretical potency ratio and R_c, the experimentally calculated potency ratio. R_2 and R_1 are the upper and lower limits of R_t, calculated for $P = 0·05$.

The mean difference between the theoretical and the calculated potency ratios was 3·9 per cent, and the mean fiducial limit ($P = 0·05$) was 15·3 per cent.

Vasopressin was now assayed against oxytocin on mammary strips taken from rats which had been suckled by large litters (greater than 6) for 1–4 weeks. The age of the litter did not appear to affect the relative potency of vasopressin, which was 3·2 ± 0·24 per cent (9) that of an equal unitage of oxytocin.

Thus, mammary tissue *in vitro* has the advantage of being more specific for oxytocin than the *in vivo* preparation. Rat mammary strips provide an accurate and convenient assay method for oxytocin. Each strip can be used for approximately 3 hr., and one rat kept alive under urethane anæsthesia provides many strips over a long period of time. As described here the method is not very sensitive, 2–4 mU. being needed to produce a small response. Using a 2 ml. bath, 0·5–1·0 mU. would, presumably, give the same response, and should an ultra-sensitive assay method be required, a superfused mammary strip could be used. However, it has often been shown that such highly sensitive assays are of low precision.

This work was carried out during the tenure of a Riker fellowship and Wellcome research travel grant.

Effect of 9α-Fluoro-11β-hydroxy-17-methyltestosterone ('Ultandren') on the Testis of the Immature Rat

'ULTANDREN' (Ciba, Ltd.) is known to be an extremely potent oral androgen, approximately ten times as effective as methyltestosterone[1]. In a preliminary investigation of its effects on the testis of the immature rat comparable doses of 'Ultandren' (0·05 mgm.) and methyltestosterone ((0·5 mgm.) dissolved in 0·5 ml. polyethylene glycol were administered daily by mouth for 10 days to litters of rats aged 28–31 days. To a third group of litter mate controls 0·5 ml. of polyethylene glycol was administered daily.

After killing, one testis was removed and fixed in formol saline. Equatorial transverse sections 8μ thick were cut and stained by the periodic acid–Schiff method, with counterstaining by iron hæmatoxylin. This stain accurately depicts the various stages of the spermatogenic cycle[2].

In each testis the number of tubules showing the acrosome phase of spermiogenesis was expressed as a

Table 1

Treatment	Percentage of tubular cross-sections showing acrosome phase of spermiogenesis	Mean percentage
'Ultandren', 0·05 mgm./day	100, 83, 85, 97, 100, 82	91·1 ± 8·71
Methyltestosterone, 0·5 mgm./day	57, 50, 56	54·3 ± 3·79
Control	67, 58, 94, 72	72·8 ± 15·29

percentage of not less than 60 tubular cross-sections observed in 3 non-adjacent testicular sections. The results are indicated in Table 1.

Comparison of the results in control, 'Ultandren'- and methyltestosterone-treated animals shows that with $n_1=2$, $n_2=10$, $F=13\cdot988$, which is significant at the 0·1 per cent level, thus indicating the heterogeneity of the results of the different treatments.

It is apparent that in 'Ultandren'-treated rats the percentages of tubules showing the acrosome phase of spermiogenesis are higher than in the control animals. This difference is significant ($t=2\cdot34$, $n=8$, $P<0\cdot05>0\cdot025$).

When the methyltestosterone-treated and control animals are compared, the testes of the former group show a lower percentage of tubules in the acrosome phase. However, these differences are not significant at the 5 per cent level ($t=1\cdot95$, $n=5$, $P>0\cdot1<0\cdot2$).

Although the results using methyltestosterone are not significant it may be a depressor of spermatogenesis in the doses used. 'Ultandren', on the other hand, in approximately equally androgenic doses, accelerates the rate at which the acrosome phase of spermiogenesis is achieved in the tubules of the immature testis. This finding is of interest, since previous workers have been unable to accelerate the normal process of maturation of the testis[3-6]. It is proposed to study the matter in greater detail.

I am indebted to Ciba Laboratories, Ltd., for a grant for technical assistance and for supplies of the steroids and solvents used in this experiment.

HÆMATOLOGY

Sensitivity of Hæmoglobin to Oxidation in Various Conditions

When intact red cells are treated with weak solutions of sodium nitrite in isotonic saline, or hæmolysed red cell suspensions are treated with weak solutions of potassium ferricyanide, the red colour changes to brown as the oxyhæmoglobin is oxidized to methæmoglobin. Infants have long been known to be particularly sensitive to this change[1-3]; but it has only recently been shown[3,4] that this increased sensitivity is also present in children of both sexes up to the age of puberty.

Blood samples have been obtained from pregnant women (100), patients with carcinomata (51), other hospital patients (52) and medical and physiotherapy students (100). 96 per cent of pregnancies of more than 6-weeks duration exhibited increased sensitivity of the hæmoglobin to oxidation. A similar, but less-marked, change occurred in the patients with definite carcinomata. Of the other hospital patients only those with acute coronary thrombosis, hæmolytic blood diseases, multiple fractures or severe rheumatoid arthritis showed any deviation from the normal. No case of increased sensitivity occurred in any of the students.

The sensitivity of the hæmoglobin to oxidation rapidly returned to normal after delivery, and, in the few cases so far examined, following complete extirpation of the malignant tumour. The cause of these changes is as yet unknown, and the phenomenon is at present being investigated. The findings will be reported in full elsewhere.

Experimental Oxidation of Hæmoglobin: its Relation to Growth-rate in Rats

The sensitivity of oxyhæmoglobin to oxidation with nitrites or ferricyanide is increased in children, pregnant women and patients with carcinomata (refs. 1–4 and preceding communication). The change-over from the increased sensitivity of childhood to the adult reaction occurs at about the age of puberty. To investigate the relationship between this reaction and the hormonal changes of puberty, the phenomenon has been studied in rats, as the growth-rate and pubertal changes can be determined and separated much more readily in small mammals than in man.

Rats' hæmoglobin has approximately the same resistance to oxidation as human hæmoglobin and exhibits the same increased sensitivity in the young and pregnant. The growth-rate of some 60 female Lister hooded Worcester sub-strain rats was determined and related to the oxidation sensitivity of their hæmoglobin. Fig. 1 shows that the change-over from the juvenile type of resistance to oxidation occurs at 40–50 gm., which corresponds closely to the time of most rapid change in the growth-rate (40–

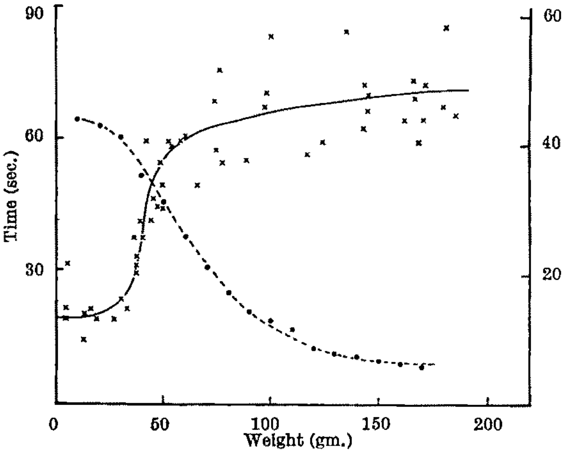

Fig. 1. —×—, Conversion time ; - - ● - - , growth-rate

50 gm.). Puberty, in this strain, as judged by vaginal opening, occurs at 100–110 gm.

These findings strongly suggest that the resistance of hæmoglobin to methæmoglobinization is more closely connected with changes in growth-rate than with any hormonal change associated with puberty.

Incomplete Antibodies to Chicken Red Cell Antigens

The evidence supporting the existence of incomplete antibodies to chicken red cell antigens is inconclusive[1], and the following experiments were carried out to see if incomplete antibodies, similar to those against the red cell antigens of man, would be demonstrated :

(1) *Heat inactivation.* Sera containing complete agglutinins were diluted 1/4 and then heated for 10 min. at 70° C. The heated sera were then tested against the appropriate cells in saline, by an albumin replacement technique[2] and by a spin antiglobulin technique using rabbit anti-chicken serum. The results obtained are given in Table 1 (scoring as suggested by Dunsford and Bowley[2]).

Table 1

Serum No.	Specificity	Red cells	Saline	Albumin	Antiglobulin test
244 *B*	anti-*B* 32	*B* 32/32	–	–	*V*
296 *A*	anti-*B* 38	*B* 38/38	–	–	+ +
242 *A*	anti-*B* 43	*B* 43/43	–	–	+ +
358 *A*	anti-*B* 39 and *B* 41	*B* 32/39	–	–	+ +
380 *A*	anti-*B* 44	*B* 44/46	–	–	+ +

(2) *Titration.* Each of the sera of Table 1 was serially diluted, using saline as diluent, and tested against the corresponding cells suspended in saline. The results were read by microscope. The red cells from all the tests giving no agglutination were then well washed four times and tested with anti-chicken serum by the spin antiglobulin technique. The first two positive results of each titration obtained by this method were interpreted as possible enhancement of the reaction of the complete antibody. Any positive results beyond these two were considered due to incomplete antibodies. All seven sera showed this evidence and the results given in Table 2 are typical.

Table 2

Serum 296 *A*	1	5	10	20	40	80	160	320	640	1,280
Saline	*A*	*A*	*A*	*N*	*N*	*N*	*N*	*N*	*N*	*N*
Antiglobulin	Not tested*			*A*	*A*	*A*	*A*	*A*	*N*	*N*

A, Agglutination; *N*, no agglutination.
* Not tested because agglutination was strong.

(3) Sera were obtained from twelve birds which had been inoculated with red cells to produce specific antisera but, judged by saline agglutination methods, they had not been immunized. Serum from each bird was examined against the corresponding cells by saline, albumin and spin antiglobulin techniques. Four of the sera were found to have incomplete antibodies demonstrable by the antiglobulin technique only. These sera were also diluted and heated as in the first experiment and re-tested by the antiglobulin technique. The antibodies were still demonstrable, showing them to be thermostable.

These experiments leave no doubt as to the existence of incomplete antibodies to chicken red cells. Fuller details of the methods used, specificity of the antibodies, etc., will be published elsewhere later.

Circulating Platelets in Mice subjected to Simultaneous X-ray and Ultra-violet Irradiation

The circulating platelet count of mice increases significantly after ultra-violet irradiation. Five to seven days after a single whole-body ultra-violet irradiation the increase is about 100 per cent. Parabiosis experiments, as well as the positive effect of isologous serum transfer, suggested that humoral factor(s) are responsible for the thrombocytopoietic effect and the agent seemed to be a protein-like macromolecule[1] as already described for human serum[2]. In the present experiments we investigated the simultaneous action of whole-body X-ray irradiation, that is, a procedure causing severe thrombocytopenia, and ultra-violet radiation, that is, a procedure causing marked thrombocytosis.

Mice weighing 20 gm. were subjected to ultra-violet irradiation using a Hanau quartz-lamp (no filter, 210 V., 5·2 amp., 50 cm. distance, 30 min.). The dose of whole-body X-ray irradiation was 300 r. (0·5 copper, 180 kV., 10 m.amp., 50 cm. distance). Platelets were counted by a direct phase-contrast microscope method as described by Feissly and Lüdin[3]. 0·2 ml. sera from ultra-violet irradiated mice was injected into the tail vein of recipients.

In the first experiments sixty mice were subjected to ultra-violet irradiation and five animals were killed at each interval marked on Fig. 1. The serum of these animals was given intravenously to 5–10 recipient mice in each group. Platelets were enumerated

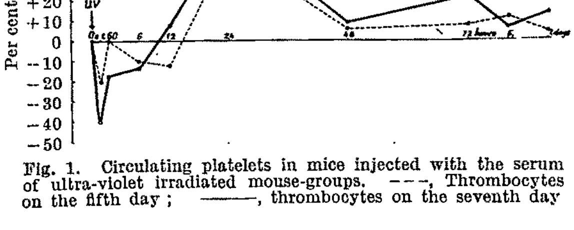

Fig. 1. Circulating platelets in mice injected with the serum of ultra-violet irradiated mouse-groups. – – –, Thrombocytes on the fifth day ; ———, thrombocytes on the seventh day

before and 5 and 7 days after serum injections. As shown, the most pronounced thrombocytosis (50–60 per cent) resulted with sera taken 24 hr. after irradiation. Although the platelet count of irradiated animals did not diminish, early serum samples, up to 6 hr. after irradiation, tended to diminish the platelet count of recipient mice.

As Fig. 2 demonstrates, about 60 per cent diminution of circulating platelets followed the 300 r. whole-body X-ray irradiation of mice 10 days later. However, if ultra-violet irradiation was given 24 hr. before this X-ray dose, (*a*) the platelet count did not diminish at all, and an average 21 per cent increase occurred on the tenth day. Furthermore, as demonstrated by (*b*), even ultra-violet irradiation administered 24 hr. after X-rays significantly reduced platelet count diminution.

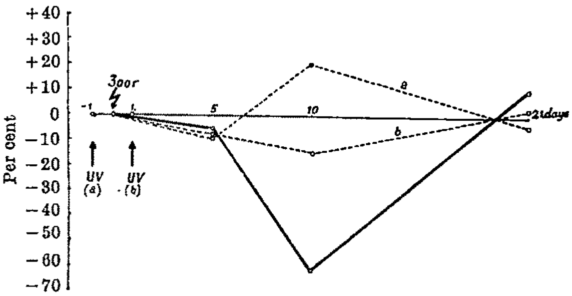

Fig. 2. Circulating platelets in mice subjected to simultaneous X-ray and ultra-violet irradiation. The solid line represents the platelet count of X-ray irradiated animals

In Fig. 3 we see that sera taken from mice treated with ultra-violet irradiation 24 hr. before prevent thrombocytopenia when given 24 hr. after the above X-ray dose (*a*), but cannot prevent thrombocytopenia 5 days after the X-ray injury (*b*).

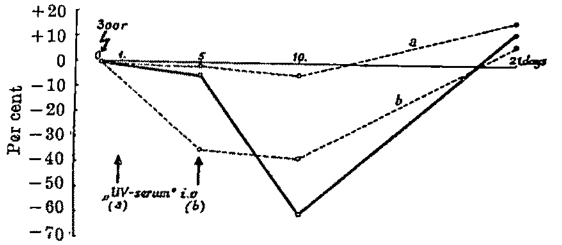

Fig. 3. Circulating platelets in X-ray irradiated mice injected with sera from ultra-violet irradiated mouse-groups. The solid line represents the platelet count of X-ray irradiated animals

X-ray induced thrombocytopenia results from the injury of the megakaryocyte system. It is of some interest, therefore, that the agents which are responsible for the thrombocytosis of whole-body ultra-violet irradiation are effectively present even in mice treated with 300 r. Perhaps these agents do not originate from the bone marrow. On the other hand, the failure of an otherwise effective ultra-violet-light activated serum 5 days after total-body irradiation suggests that the target organ of this thrombocytopoietic factor is the bone marrow.

RADIOBIOLOGY

Incorporation of Thymidine into Deoxyribonucleic Acid by Extracts from Bacteria exposed to Ultra-violet Light

Ultra-violet light induces a lag in the synthesis of deoxyribonucleic (DNA) acid in *Escherichia coli*[1]. After a dose-dependent incubation interval, the irradiated bacteria will resume synthesis at almost the same rate as prior to exposure. Recently, various investigators[2–4] have shown that blockage of ribonucleic acid (RNA) or protein synthesis prevents the recovery of DNA synthesis in bacteria irradiated with ultra-violet light. The capacity of the bacteria to synthesize DNA after exposure is regained with the initial doubling of RNA in the culture[5].

In this investigation, by measuring ^{3}H-thymidine incorporation into an alkaline-stable, DNAase-sensitive, cold acid-insoluble fraction[6], it has been determined that following exposure to doses of ultra-violet light which inhibit net DNA synthesis *in vivo*, cell extracts showed unimpaired thymidine phosphorylase and DNA polymerase activity. In addition, an increase in activity was noted in the extracts from exposed cells that had been re-incubated in a growth medium. In the system used here ^{3}H-thymidine incorporation into DNA depends on the presence of the other three deoxyriboses in the triphosphate form[6]. This strongly suggests that we are measuring DNA replication rather than thymidine replacement in the pre-formed DNA. Kornberg *et al.*[7,8] and Lehman *et al.*[9] have shown that the polymerase present in a crude enzyme preparation from another strain of *E. coli* is capable of net DNA synthesis.

Cultures of *E. coli* strain *B/r* in the exponential phase of growth were exposed to ultra-violet light from a Hanovia model 30,600 high-pressure mercury vapour arc lamp. The techniques used for radiation exposure, determination of numbers of colony-forming organisms and the measurement of RNA, DNA and protein have been described[10]. The coli suspension at a depth of 1·5 mm. was exposed to 980 ergs per mm.^{2} ultra-violet light while being stirred vigorously. The cells were broken in a French pressure cell to yield the extracts tested[6]. By centrifugation at 10,000*g* for 20 min., a pellet of intact cells and cellular debris was formed. The resultant extracts contained less than 10^3 colony-forming bacteria per mgm. protein.

This dose of ultra-violet light does not decrease the activity of the thymidine-incorporating enzymes found in the extracts from the exposed cells (Table 1). This exposure is effective in delaying *in vivo* synthesis of DNA for a period of 75 min. Furthermore, during this period, in which synthesis of DNA is blocked, a considerable increase in RNA, protein and the thymidine-incorporating enzymes is observed. Additional experiments with higher doses of ultra-violet light have shown that exposures sufficient to reduce survival as low as 0·1 per cent do not diminish the capacity of extracts from such cells to incorporate thymidine into DNA.

If the enzymatic activity present in the extracts reflects the enzyme content of the intact cells, then these results indicate that the blockage of synthesis of DNA by ultra-violet cannot be ascribed to an effect on the polymerase or the enzymes responsible for phosphorylation of thymidine. These results are comparable to those of Billen, who determined that

Table 1. EFFECT OF ULTRA-VIOLET LIGHT ON SURVIVAL AND SYNTHESIS OF NUCLEIC ACIDS AND PROTEIN BY *Escherichia coli* STRAIN B/R AND ON THE ^{3}H-THYMIDINE-INCORPORATING CAPACITY OF BACTERIAL EXTRACTS

* μμmoles of ^{3}H-thymidine incorporated in 20 min. The extract used per reaction vessel is equivalent to 4 ml. of the bacterial suspension

† μμmoles of ^{3}H-thymidine incorporation into DNA per mgm. of extract protein.

extracts from cells lacking a component of the DNA synthesizing system because of amino-acid starvation[11] possessed enzymatic activity for DNA synthesis *in vitro* equivalent to cells fully capable of DNA synthesis[6]. It seems clear that the blockage of DNA synthesis, either by ultra-violet light or amino-acid starvation, cannot be ascribed to an effect on DNA polymerase *per se*. While the possibility exists that the extraction procedure may remove the enzymes from some inhibitory effect of the ultra-violet light, this possibility seems less likely in the case of the enzymes synthesized after exposure to ultra-violet light. Thus, at 60-min. incubation, the enzymatic activity in the extract has doubled while DNA synthesis *in vivo* remains blocked for an additional 15 min.

Though these investigations have not measured the activities of the kinases of the nucleosides other than thymidine, it seems unlikely that the blockage of DNA synthesis by ultra-violet light can be ascribed to an inhibition of synthesis of any of the deoxyribonucleotides, since Kanizir and Errera[12] found extensive accumulation of deoxyribonucleotides *in vivo* following exposure to ultra-violet light. Rather, it would appear that we must ascribe the ultra-violet light block to an effect on some other component of the *in vivo* DNA-synthesizing system which is restorable through RNA and protein synthesis following exposure. In view of the results of Doudney and Haas[5], which relate ultra-violet-induced mutation to the restoration of this component of the DNA-synthesizing system, it may be predicted that the component plays an intimate part in the transfer of genetic specificity from parental to daughter DNA.

This investigation was supported in part by the U.S. Atomic Energy Commission.

Nitrogen Protection of Fecundity and Fertility in Female *Habrobracon* treated with X-rays

BRACONID anoxia experiments were performed as a logical sequel to investigations with ingested chemical protectors[1]. In both cases, damage was assessed by scoring the eggs produced per unit of time and the larvæ emerging therefrom. Eggs are dispensed in exact order from the single developmental series identical for each of the four ovarioles. This feature makes it possible to correlate quantitative modifications in the number of eggs, and their hatchability, with the cellular state at the time of irradiation.

Cysteine or glutathione fed to female *Habrobracon* prior to irradiation protected a significant fraction of the cells which afterwards gave rise to the eggs laid toward the end of the first week and at the beginning of the second[1]. At the time of exposure the cells involved were mitotically active and engaged in transition from oogonia to differentiated trophocyte–oocyte units. According to a widely accepted hypothesis, the sulphydryl types of protective compounds operate by reducing the availability of oxygen in irradiated cells. The present experiments were carried out to determine whether anoxia by gas replacement would protect only the mitotically active cells or whether protection could be extended to all the cell types present in the wasp ovariole.

The virgin females used were isolated from stock No. 33 (Whiting) of *Habrobracon juglandis* = *Bracon hebetor*. Groups of 15 were irradiated in the small plastic chambers developed during the examination of gas modification of radiosensitivity of developing *Habrobracon*[2]. In gas replacement experiments nitrogen was passed through the chamber for two minutes before sealing. Including two minutes of such flushing, the wasps were in nitrogen for a total of 15 min. X-rays were delivered by the Woods Hole Marine Biological Laboratory generator, which operates at 28 m.amp. and 200-kV. peak with filtration equivalent to 0·2 mm. of copper.

Exposures in both air and nitrogen were made at 2,250 r. and 4,500 r. A higher series of doses ranging from 9,000 r. to 13,600 r. were delivered in nitrogen. An unirradiated group given nitrogen for 15 min. demonstrated that such treatment did not decrease egg production.

A nitrogen atmosphere afforded nearly complete protection from the 2,500 r. dose. Except on days 3, 4, and 5 egg production was not significantly lower than controls. In fact, on a majority of days control values were exceeded. Fig. 1 presents egg production after higher doses selected for contrast and comparison. 4,500 r. delivered in air is near the threshold for permanent infecundity[3]; but if delivered in nitrogen is found to be much less effective. Indeed, during the latter part of life, egg production compares well with

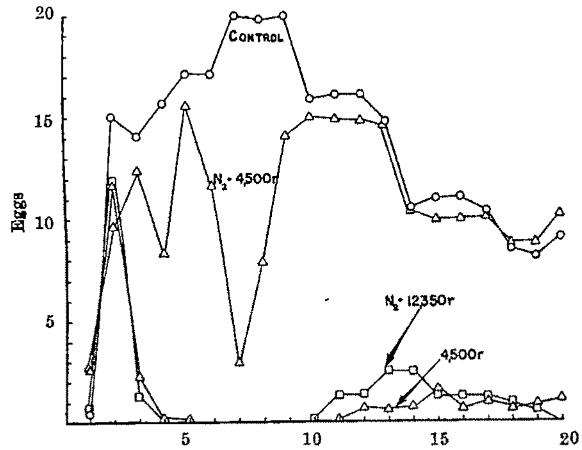

Fig. 1

control values. The eggs deposited during this period are derived from cells which were oogonia at the time of treatment.

The nitrogen series provided a family of curves demonstrating that low egg production equivalent to that following 4,500 r. in air is attained between 12,350 and 13,600 r. Records for the former are shown in Fig. 1. The higher dose resulted in only scattered eggs on the 12th to 14th days. For the sake of clarity the family of curves obtained in the nitrogen series is not shown in the graph. In a regular expected order they would fill in the space between the 4,500 r. and the 12,350 r. curves.

A summary of hatchability for the eggs of Fig. 1 is shown by Table 1. The basis of comparison reflects cytological conditions of the developing units at the time of irradiation. Protection afforded by the replacement of air by nitrogen is apparent not only in a significantly higher hatchability after 4,500 r. but also in hatchability which approaches control values after the eleventh day. Standard errors range from 1 to 3 per cent. Hatchability records for the 12,350 r. nitrogen experiment are included as a demonstration that larvæ are obtained from eggs laid during both the decline phase and recovery phase of egg production. No exactly comparable data are available.

These results demonstrate that the protective effect of gas replacement anoxia is afforded to all types of cells in the polytrophic ovariole. They comprise differentiated, transitional and primitive cells. The progress of meiotic prophase, mitosis, and interphase characterizes the respective periods, with mitotic activity explaining the radiosensitive 6–10 day period. Limitation of protection by SH compounds to the sensitive period might indicate merely a selective concentration of the chemical substances and localized reduction of oxygen availability. Alternatively, the present results would raise the question of whether reduced oxygen is the explanation of sulphydryl protection. This alternative is an interesting possibility in view of the recent demonstration that the mode of action of cysteine includes one reaction that can occur independently of oxygen[4].

Table 1. PERCENTAGE OF HATCHABILITY FOR EGGS OF FIG. 1. 5-DAY PERIODS REFER TO THE CYTOLOGICAL CONDITION OF THE CELLS AT THE TIME OF IRRADIATION FROM WHICH EGGS MAY AFTERWARDS BE OBTAINED DURING THE PERIODS INDICATED

Reversal of γ-Ray-induced Dormancy of Potato Tubers by Gibberellic Acid

POTATOES (var. Up-to-date), which were free from sprouting, were packed in polyvinyl chloride bags and irradiated with 8,000 and 12,000 rads of γ-rays during a 'shut-down' period of the swimming-pool-type reactor *Apsara*. The dose-rate during the period of irradiation was 200 rads/min. Based on a sample of 81 potatoes in each case, the numbers sprouting, 35 days after irradiation, were 81 in control, 9 with a dose of 8,000 rads and none with a dose of 12,000 rads.

γ-Ray-treated potatoes were dipped for 5 min. in 250 and 500 p.p.m. solutions of sodium salt of gibberellic acid, 35 days after irradiation. In the case of potatoes irradiated with 8,000 rads, only those free from sprouting were chosen for treatment with gibberellic acid. The control potatoes were dipped in distilled water for 5 min. The results are recorded in Table 1. In the potatoes treated with 8,000 rads of γ-rays, 20 out of 20 potatoes sprouted in 10 days with 500 p.p.m. and in 15 days with 250 p.p.m. of gibberellic acid. Similarly, in the case of potatoes that had received a dose of 12,000 rads of γ-rays, 20 out of 20 potatoes sprouted in 15 days with 500 p.p.m. and in 20 days with 250 p.p.m. of gibberellic acid.

As a result of irradiation with 8,000 and 12,000 rads of γ-rays, the buds on the potatoes degenerated. Similar degeneration of potato buds as a result of γ-irradiation has been observed by other workers[1,2] also. In the present experiment, new buds arose

Table 1. EFFECT OF GIBBERELLIC ACID ON THE REVERSAL OF γ-RAY-INDUCED DORMANCY OF POTATO TUBERS STORED AT 23–32° C. (RELATIVE HUMIDITY, 75–95 PER CENT)

Treatments (γ-radiation in rads : gibberellic acid in p.p.m.)	No. of tubers	No. sprouting after, days			
		5	10	15	20
(1) 8,000 : 0·0	20	Nil	Nil	Nil	Nil
(2) 8,000 : 250	20	7	16	20	20
(3) 8,000 : 500	20	13	20	20	20
(4) 12,000 : 0·0	20	Nil	Nil	Nil	Nil
(5) 12,000 : 250	20	5	12	17	20
(6) 12,000 : 500	20	8	14	20	20

adjacent to those degenerated after treatment with gibberellic acid.

It appears that γ-irradiation impairs a possible endogenous gibberellin-synthesizing system in the potato and that the effects of this damage can be counterbalanced by exogenous gibberellic acid.

Incorporation of Phosphoryl-choline labelled with Phosphorus-32 into the Liver Phospholipids of Rats treated with Growth Hormone

THE rate of incorporation of acetate labelled with carbon-14 into the liver phospholipids of rats treated with growth hormone is reduced to about 50 per cent of that found in normal animals[1]. On the other hand the rate of incorporation of orthophosphate labelled with phosphorus-32 in similarly treated animals is increased by about 30 per cent[2]. It thus appeared that growth hormone might affect the rates of synthesis of the fatty acid skeleton and the phosphoryl-base moiety separately.

Table 1. EFFECT OF PITUITARY GROWTH HORMONE ON THE INCORPORATION OF ORTHOPHOSPHATE-^{32}P, GLYCINE-2-^{14}C AND ACETATE-1-^{14}C INTO PHOSPHOLIPIDS OF RAT LIVER SLICES

Precursor	Specific activity (counts/100 sec./mgm.)			Total incorporation (counts/100 sec./flask)		
	Hormone-treated	Control	$\frac{\text{Treated} \times 100}{\text{Control}}$	Hormone-treated	Control	$\frac{\text{Treated} \times 100}{\text{Control}}$
Orthophosphate-^{32}P	1,024	1,042	98	8,735	6,731	130
Glycine-2-^{14}C	969	977	99	8,266	6,311	131
Acetate-1-^{14}C	139	805	17	1,186	5,200	23

Adult female rats were injected with 1 mgm. pituitary growth hormone 6 hr. before killing. The rats were killed and the livers rapidly excised and slices cut on a Stadie–Riggs microtome[3]. 400 mgm. slices were incubated for 3 hr. in 5 ml. Krebs–Ringer bicarbonate (gassed with 95 per cent oxygen–5 per cent carbon dioxide) in the presence of either 0·5 μc. $H_3{}^{32}PO_4$, glycine-2-^{14}C or sodium acetate-1-^{14}C. At the end of the incubation the slices were collected and homogenized in 5 ml. 5 per cent trichloroacetic acid. The phospholipids were separated, plated and counted as described previously[1]. The results of such an experiment are given in Table 1.

It will be seen that, on the basis of specific activity, there is no change in the rate of incorporation of either orthophosphate or glycine, but acetate incorporation is greatly reduced. However, in view of the massive mobilization of lipids to the liver[4], the values for the specific activities are not as meaningful as the total counts incorporated, also given in Table 1. From these it will be seen that there is a reduced rate of incorporation of acetate, but an increased incorporation of phosphate and glycine which fully confirms the previous results. Because there is a strong possibility that the phospholipins as extracted above might be more or less contaminated with phosphatidic acids, the phospholipids obtained were further purified by adsorption chromatography by Kennedy's method[5]. The results obtained with this purified material were the same as those already described.

Since the glycine is only incorporated into the base of phospholipids[6], it would thus appear that both the phosphate and the base are incorporated more rapidly in the hormone-treated animals than in the controls. Since this could be due either to a more rapid rate of formation of phosphoryl-base or, alternatively, to a more rapid incorporation of the phosphorylated base into phospholipin, we have investigated the incorporation of phosphoryl-choline into the liver phospholipids of normal and growth hormone-treated animals.

Phosphoryl-choline labelled with phosphorus-32 was prepared according to Riley's method[7], and calcium ion was removed by use of an exchange resin '*IR*–120' (K^+ cycle). The rats were injected as above and the livers removed. A 'particle fraction', prepared according to Kennedy[8], was used for the incorporation experiments. The incubation period was 1 hr. The phospholipids were extracted and purified according to Kennedy[8] and counted as before. The results are given in Table 2.

In each of the three experiments the phosphoryl-choline was incorporated into the phospholipids of the injected animals at a rate about one-third greater than in the control animals, that is, at about the same rate as the incorporation of phosphorus and glycine.

To account for these results two explanations may be advanced: (1) that there exists a smaller pool of phosphoryl-choline in the livers of the injected animals; (2) that there is an increased rate of phospholipin synthesis in the livers of the hormone-treated animals. In this second case the very much lower rate of incorporation of acetate in the injected animals may be accounted for in terms of the inhibition of some step between acetate and diglyceride, or alternatively to a dilution of the diglyceride pool in the livers of growth hormone-treated animals. It has already been suggested that the incorporation of

Table 2. EFFECT OF PITUITARY GROWTH HORMONE ON THE INCORPORATION OF ^{32}P-CHOLINE INTO THE PHOSPHOLIPIDS OF RAT LIVER 'PARTICLES'

Exp.	^{32}P-Choline added (μmoles/flask)	^{32}P-Choline incorporated (mμmoles/flask)		
		Growth hormone-treated	Control	$\frac{\text{Treated} \times 100}{\text{Control}}$
I	4	6·3	4·6	137
II	18	12·3	9·5	129
III	20	21·6	14·1	153

Each flask contained initially 100 μmoles of phosphate buffer, *p*H 7·4, 10 μmoles ATP, 1·5 μmoles CTP, 20 μmoles $MgCl_2$, ^{32}P-Choline (33,700 c.p.m. per micromole) as indicated and 'particles' derived from 0·4 gm. liver. 1·5 μmoles of ATP and 0·03 μmoles of CTP were added every 12 min. during the course of the experiment. The flasks were incubated at 37° C. for 1 hr.

acetate into fatty acids is greatly reduced in growth hormone-treated rats[1] and experiments are now in progress to establish whether there is another block between fatty acids and diglycerides and whether there is a dilution of the diglyceride pool.

PATHOLOGY

The Liver in Infective Hepatitis

THE changes in the liver during the acute stage of infective hepatitis consist of marked alterations to the liver cells, especially in the central regions of the lobule, and an infiltration of the portal tracts and sinusoids with inflammatory cells. Except in fatal cases, necrosis of liver cells is infrequent[1-4]. The disease is thought to be a virus infection of the hepatic parenchyma; but the causative organism or organisms have so far eluded laboratory isolation[5].

This communication reports the results of work on 26 needle biopsies which have been carried out on the livers of African soldiers suffering from infective hepatitis. Biopsies were performed between 5 and 73 days after the onset of disease. For comparison, liver biopsies have also been performed on healthy human volunteers. Liver specimens have been studied by a variety of cytological and cytochemical methods and by electron microscopy after conventional osmium fixation and methacrylate embedding.

Histological examination of the infective hepatitis livers showed the typical parenchymal and stromal changes of this disease. Although the sequence of liver cell alterations could not always be accurately determined, the earliest change, as shown by light microscopy, appears to be enlargement of the nucleolus and a concurrent increase in ribonucleoprotein. This increase in ribonucleoprotein is progressive, and later results in marked enlargement and distortion of the nucleolus. The nucleus also becomes swollen; but an increase in nucleoprotein has not been detected in the nucleoplasm. While these changes are taking place, the cytoplasm shows a progressive increase in ribonucleoprotein which commences in the region of the nucleus but later fills most or all the cell. Cytochemical tests indicate that this newly formed ribonucleoprotein contains the amino-acids, arginine, typtophan and tyrosine, and small amounts of cysteine and cystine. It does not contain deoxyribonucleic acid.

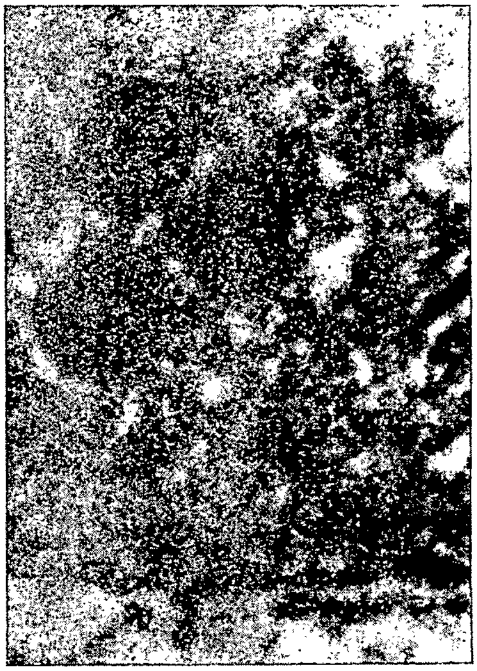

Fig. 1. Periphery of liver cell showing numerous roughly spherical bodies in the cytoplasmic matrix. (× 23,700)

In some cells the mitochondria show variable degrees of swelling; in others they appear increased in number. The Golgi complex is clearly seen in healthy biopsies, but because it is not demonstrable in infective hepatitis livers it is thought to have undergone degeneration.

Electron microscope studies on 14 infective hepatitis livers reveal marked cell changes in all cases. In some instances the nucleoplasm exhibits an increased amount of granular material and the nucleoli are often distorted. Within the cytoplasm the endoplasmic reticulum is usually dilated, and the mitochondria are often grossly swollen. In some cells, however, the mitochondria are increased in numbers, fresh forms arising from existing mitochondria. Not infrequently the microbodies are increased also. The cytoplasmic matrix of some liver cells contains numerous granules which measure approximately 21·5 mμ in diameter and, therefore, are larger than the ribonucleoprotein-containing granules of healthy cells. Often 6–12 of these granules appear to be aggregating to form irregularly spherical bodies measuring 76–103 mμ in diameter (Fig. 1). Such spherical bodies were seen in 7 of the 14 infective hepatitis livers but in none of 6 healthy livers. In one case they were present 29 days after the onset of disease. The bodies are always confined to the cytoplasmic matrix, but occasionally they appear to be passing from the liver cells into the sinusoids and are present in the blood serum. Spherical bodies, varying between 30 and 70 mμ, have already been visualized in the cytoplasm of liver cells in infective hepatitis[6,7].

Although it has not been possible to determine accurately the progression of liver cell changes in infective hepatitis, it is thought that it parallels the sequence of alterations which occur in the liver cells of rhesus monkeys infected with yellow fever[8]. In this latter condition there is an increased synthesis of ribonucleoprotein in the nucleolus. The newly formed ribonucleoprotein passes in a finely granular state through the nucleoplasm to the cytoplasmic matrix. In the matrix the granules aggregate to form small rosettes which later contract to give rise to spherical virus particles. Although further on infective hepatitis is required before the true nature of the spherical bodies is elucidated, it is considered on the basis of present evidence that they may possibly represent the causative virus.

More detailed reports on the liver in infective hepatitis are to be published later.

Precipitation Reaction between Serum and Lysed Erythrocytes

Human serum reacts with hæmolysates of human erythrocytes to form a precipitate; this occurs even with the isologous hæmolysate. When the hæmolysate is added to serum in tubes at 37° C., precipitation continues for several days. In agar-gel, using a double diffusion technique, a well-marked precipitate band is formed (Fig. 1). Peetoom *et al.*[1] described a precipitate of this type in agar-gel, but only minimal precipitation in fluid media. In spite of antigenic differences between adult and fœtal hæmoglobins[2], serum and hæmolysate from adult and umbilical cord blood form precipitates in agar-gel, which are qualitatively the same. Cross-precipitation also occurs between human and some animal sera and hæmolysates. As the reaction is of general occurrence, it causes false positive results in tests for auto-antibodies when the tissue extract used as antigen contains sufficient lysed erythrocytes.

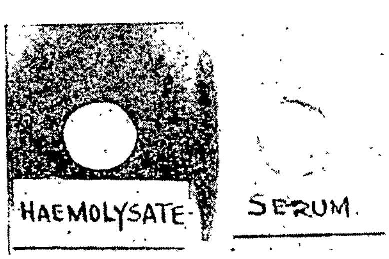

Fig. 1. Precipitate band formed by double diffusion of serum and hæmolysate in agar-gel

The precipitate forms with serum and hæmolysate from blood of the same or different *ABO* blood-groups. After absorption of the α- and β-antibodies with intact erythrocytes, serum continues to form the precipitate. The cell envelope is not involved, as precipitation occurs with Seitz-filtered hæmolysates. Thus, the reaction is independent of the *ABO* groups.

Although haptoglobins were not detected by Tuttle[3] in cord blood, serum from cord blood gives a precipitate with adult and cord hæmolysates. Also adult serum, after absorption for 3 days at 37° C. with hæmolysate containing 8–12 mgm. hæmoglobin per ml., loses its ability to precipitate with hæmolysate in agar-gel; but Allison *et al.*[4] found that the haptoglobins in 1 ml. of serum could react with only 1·35 mgm. of hæmoglobin. Therefore, serum factors other than haptoglobins must be involved.

The reaction titres of sera from normal adult and cord blood, tested in agar-gel, are similar; but some sera from cases of hæmolytic disease of the new-born and of acute hæmolytic anæmia have reduced titres. Thus, this precipitation reaction may be part of the physiological mechanism for the removal of products of erythrocyte lysis.

Antigenicity of Deoxyribonucleic Acids from Mouse Liver and from the Ehrlich Ascites Tumour

In recent years, a number of reports have appeared concerning the antigenicity of mammalian and bacterial deoxyribonucleic acid. Evidence has been presented indicating that complement-fixing[1] and precipitating[2] antibodies may be produced by the injection of such preparations into experimental animals. In addition, serum from patients with systemic lupus erythematosus has been shown to react immunologically with highly purified deoxyribonucleic acid from a variety of sources[3]. The present communication concerns the production of antisera by the immunization of rabbits with deoxyribonucleic acid preparations isolated from mouse liver and from cells of the Ehrlich ascites tumour. The results obtained indicate that anti-tumour cell deoxyribonucleic acid serum has an inhibitory effect on the growth of the tumour *in vivo*.

Mouse liver and Ehrlich tumour cell deoxyribonucleic acids were isolated by the detergent method of Kay, Simmons and Dounce[4]. The preparations had nitrogen/phosphorus ratios of 1·65–1·68. In the analytical ultracentrifuge (Spinco, model *E*) equipped with an ultra-violet optical system, solutions containing 25–30γ DNA/ml. in 0·2 *M* potassium chloride – 0·01 *M* phosphate buffer, *p*H 7·0, were found to contain components having sedimentation velocities ranging from 20 to 40 Svedberg units, with mean sedimentation velocities of 24–25 *S*. Contamination with polypeptide material was minimal. One-dimensional paper chromatography of hydrochloric acid hydrolysates of the deoxyribonucleic acid (using methyl ethyl ketone/glacial acetic acid/water, 2:1:1, as solvent) revealed the presence of amino-acids with the R_F values of leucine (0·04–0·08 per cent), methionine (0·02–0·04 per cent), glutamic acid (0·008–0·016 per cent), arginine (0·01–0·02 per cent) and lysine (0·02–0·06 per cent). Polysaccharides containing hexosamine could not be detected by the Rimington[5] modification of the method of Elson and Morgan[6]; that is, if such substances were present they represented less than 0·01 per cent of the nucleic acid preparations.

Antisera were produced in rabbits (New Zealand whites) either by the intravenous injection of solutions of the deoxyribonucleic acids in physiological saline or by the intramuscular injection of the nucleic acids suspended in Freund's adjuvant. In the first case (pool 1), each rabbit received 4·0 ml. of deoxyribonucleic acid solution (containing 3 mgm./ml.) twice weekly for a total of eight injections. In the second case (pool 2), each rabbit was injected twice-weekly for a total of eight injections with 4 ml. of antigen suspension containing 2 mgm. deoxyribonucleic acid per ml. Rabbits were bled by cardiac puncture two weeks after the final injection. In each case, the sera from three immunized rabbits were pooled before testing. Normal rabbit serum was obtained from the same rabbits prior to immunization.

The two methods of immunization yielded antisera of much the same potency. In complement fixation tests, performed by a slight modification of the Kolmer–Boerner technique[7] employing 250γ antigen per tube, complete fixation was observed with serum dilutions of 1 : 128 to 1 : 256. Illustrative results are presented in Table 1. Although the antisera appeared to react somewhat more extensively with the homologous than with the heterologous antigen (with the exception of the reaction between anti-mouse liver DNA serum and DNA isolated from the *AH*130 rat ascites hepatoma) the results in Table 1 do not permit one to make a case for their specificity.

Table 1. COMPLEMENT-FIXATION TESTS WITH SERA FROM RABBITS IMMUNIZED WITH DEOXYRIBONUCLEIC ACID ISOLATED FROM MOUSE LIVER AND FROM THE EHRLICH ASCITES TUMOUR

Serum	Antigen*	Complement-fixation titres†
Anti-Ehrlich DNA, pool 1	Ehrlich DNA	128

	6*C*3*HED* lymphosarcoma DNA	32
	DBA lymphoma DNA	64

* Concentration employed in complement-fixation test = 250γ/tube.

† Expressed as reciprocal of serum dilution showing complete fixation of complement.

Investigations of the effects of the antisera on the growth of the Ehrlich ascites tumour in mice do suggest, however, that the antisera have some measure of specificity. The antisera were tested in the following manner for their ability to inhibit tumour growth. The cell concentration in a pool of ascitic fluid was adjusted to the desired value (40 or 80 × 10^6/ml.) by the addition of Hanks's balanced salt solution. Aliquots of this cell suspension were mixed either with equal volumes of the antisera or with normal rabbit serum. Mice were injected intraperitoneally with 0·25 ml. (2·5 or 5·0 × 10^6 cells) of the resulting cell suspensions. In each experiment, mice injected with cell antiserum mixtures were divided into two groups. One group received no further treatment; mice in the second were injected with antiserum subsequent to tumour implantation according to the schedule indicated in Table 2.

Table 2. EFFECT OF ANTISERA PRODUCED IN RABBITS AGAINST EHRLICH ASCITES TUMOUR AND MOUSE LIVER DEOXYRIBONUCLEIC ACIDS ON THE GROWTH OF THE EHRLICH TUMOUR IN MICE

,, ‡	,,	0/10	27·6	< 0·001
Anti-Ehrlich DNA (pool 2)*	,,	0/10	25·8	< 0·001
,, ‡	,,	7/10	31·7	< 0·01, > 0·001

* No post-tumour implantation therapy.

† 0·25 ml. serum injected intraperitoneally 24 and 72 hr. post-tumour implantation.

‡ 0·50 ml. serum injected intraperitoneally 24 hr. post-tumour implantation.

§ Probability of mean differing from that of controls by chance alone calculated by the *t* test.

The results of these experiments are summarized in Table 2. Antiserum against mouse liver DNA was without significant effect on tumour growth. Of sixty mice injected with Ehrlich cells suspended in this anti-serum, sixty developed and died of the ascites tumour; and in only one of three experiments was there a significant increase in mean survival-time compared with the control group. In contrast, mice which died with ascites following injection with cells plus anti-Ehrlich DNA serum showed in every case a significant increase in mean survival-time compared with the control group. More significant was the fact that, of thirty mice in this category which received some post-tumour implantation therapy, fourteen survived without evidence of tumour development, either in ascites or solid form, during the observation period of sixty days.

These results provide evidence that highly polymerized DNA is antigenic in the rabbit when administered by the intravenous or intramuscular route. They furthermore show that antisera produced in this way possess a degree of specificity—a specificity not apparent in complement-fixation tests, but quite evident in bio-assays based on the effects of antisera on tumour growth.

Longevity in Mice with a genetically determined Muscular Dystrophy

The recent communications by Dowben[1] and Tubis *et al.*[2] regarding possible therapeutic procedures for mice with a genetically determined form of myopathy[3] have prompted this preliminary communication commenting on some problems relating to longevity in animals with this defect.

The value of such therapeutic work is three-fold. First, by prolonging the life-span of these animals it becomes possible to obtain critical details on the mechanism of the disease as it progresses. Secondly, effective therapeutic agents may give valuable leads regarding the primary metabolic nature of the defect. Thirdly; agents which prolong the life of animals with muscular dystrophy or alleviate the disease process would seem to be logical agents to employ in a clinical testing programme involving human beings with muscular dystrophy.

The last point is important because at present the rationale for employing certain therapeutic measures in patients suffering from various forms of muscular dystrophy is based largely on the results of tests in which experimental animals have been used[4]. If the results of these tests are accepted uncritically or their limitations not fully realized, it is likely that large amounts of time and money will be expended on clinical trials which unfortunately do not have the slightest probability of success.

Approximately two years ago we designed and initiated an experiment to test the efficacy of several agents in extending the life-span, and arresting the disease process, in mice suffering from a genetically determined muscular dystrophy. The agents used were felt to have potential value, by virtue of previous work either in our laboratories or in those of other investigators. It was our impression that in some reported work not enough attention had been paid to simple problems of animal management that might significantly influence the outcome of the experiments. Therefore, the method of handling the control animals in our experiment was determined by two observations made in routine mouse-colony maintenance. First, the transition period (between 2 and 2½ weeks of age), during which a suckling mouse changes to a diet of solid food, can be facilitated by the temporary use of a powdered form of the food pellet regularly used in the colony. Secondly, mice with muscular dystrophy often experience considerable difficulty in managing pelleted food and water when they are presented in the usual way through small glass tubes attached to inverted bottles. Regardless of whether these difficulties result from a generalized muscular weakness or from a particular involvement of the muscles of mastication, it was apparent that we had to entertain the hypothesis that these animals succumb to inanition resulting from their inability to consume sufficient pelleted feed or to a self-imposed inanition arising from an inadequate intake of water. It was decided, therefore, to maintain each of the animals in separate pens supplying them each day with fresh powdered food (U.B.C. mouse ration No. 6) and fresh water in small open vessels placed directly on the floor of the pen. The therapeutic substances being tested were added in appropriate levels to the powdered food.

While a number of the mice in various 'treatment' groups have lived for periods exceeding nine months, several of the untreated dystrophic animals in the control series have lived equally as long. One animal in the control group died at the age of eleven months and another still alive promises to exceed this record. So far as we are aware these are the oldest dystrophic mice yet reported.

Although the experiment is not yet complete, we believe that the results so far are significant in two principal respects: First, any claims regarding the ability of a particular agent to prolong the life-span of mice suffering from this form of muscular dystrophy must be examined with extreme caution and viewed against the background of adequately nourished control dystrophic survivors. Secondly, the progressive pathological changes previously described in this disease in the house-mouse should be re-examined in order to differentiate between those attributable to concomitant dietary deficiencies and those truly resulting from primary muscle disease.

Three additional points should be emphasized: First, not all the animals in this experiment have lived to the ages mentioned above. Secondly, there is no evidence that the disease process of the muscle is modified in any way since the affected animals still die prematurely and post-mortem examination demonstrates that muscle wasting is still extreme. Thirdly, our management procedure is begun some time after the first signs of the disease are observed[3].

On the basis of these three points we do not believe that the 'therapy' used in our experiments has any effect on the fundamental metabolic error underlying the disease, and we must stress emphatically that we are making no claims whatever about the life-prolonging ability of our diet. It seems more reasonable to believe that this ability, and perhaps that of the diet reported by Coleman[5], results from the provision of more of the essential nutrients per unit mass of feed and hence assures what is essentially an adequate intake of protein, energy and micronutrients.

A full report on this experiment together with pathological findings arising from it will be presented at a later date.

Agglutination of Sensitized Alligator Erythrocytes by Rheumatoid Factor(s)

Recently, it was found that alligator erythrocytes can be effectively used as carriers for reactant globulin in tests for rheumatoid factor(s)[1–3]. The cells are remarkable because most human sera do not contain heterophile antibodies to them, and the cells show extraordinary durability under osmotic and mechanical stress[1,2].

The present investigation was carried out to determine the effects of euglobulins from healthy individuals and from patients with rheumatoid arthritis and other diseases, in agglutination of sensitized alligator erythrocytes by rheumatoid factor(s). Globulin fractions of ovalbumin (rabbit) antiserum were also tested.

Serum euglobulin fraction[4] or other inhibitors to be tested, in 0·2-ml. serial dilutions, were mixed with 0·2 ml. volumes of positive 2 plus agglutinating serum of a patient with rheumatoid arthritis, in 10 × 75 mm. test-tubes. The mixtures were incubated at 37° C. for 30 min. before testing with sediments of 0·1 ml. of 2 per cent saline suspension of sensitized alligator cells. The agglutination of sensitized alligator erythrocytes by rheumatoid arthritis serum was not readily inhibited by the euglobulin fractions of normal sera, unless the sera were native (not inactivated at 56° C. for 30 min.) and only if sera were diluted no more than 1 : 4. In contrast, euglobulins of subjects with rheumatoid arthritis gave even stronger agglutination than the control, suggestive of an enhancement, or summation effect. Results of a typical experiment are shown in Table 1. Some degree of depression of agglutination occurred with serum euglobulins tested of 3 patients with gout, 1 with lupus erythematosus, 1 with osteoarthritis, and 1 with rheumatoid spondylitis. No inhibition or depression of agglutination was observed with the euglobulins tested of 11 rheumatoid arthritis patients. Random readings of coded dilution tubes have indicated that one can reliably distinguish macroscopically between 2 plus and 1 plus degrees of agglutination of alligator cells. The nature of the depression, or summation of agglutination of sensitized alligator erythrocytes by euglobulin fractions, is under study. Well-defined inhibition of sensitized sheep cells and coated latex particles by euglobulins of sera of normal subjects has been reported by other authors[4-7]. The degree of inhibition of sensitized alligator cells was not so remarkable as reported by workers with red cells of other species or with latex particles.

Table 1. EUGLOBULIN INHIBITION OF ALLIGATOR ERYTHROCYTE AGGLUTINATION

Subjects	Sensitized alligator erythrocyte sediment								
	Dilutions of patient euglobulin								
	1/2	1/4	1/8	1/16	1/32	1/64	1/128	1/256	Saline control
	Fixed amount of positive-reacting rheumatoid arthritis serum								
Normal (*D*)	0	0	1	1	1	1	1	1	1
Normal (*C*)	0	1	1	1	1	1	1	1	1
Rheumatoid arthritis (*T*)	2	2	2	2	2	1	1	1	1
Rheumatoid arthritis (*S*)	2	2	2	2	2	1	1	1	1

Agglutination of sensitized alligator cells by 1 volume of rheumatoid arthritis serum was readily inhibited by addition of 1 vol. of 5 per cent human, rabbit, or bovine γ-globulins. However, 5 per cent bovine albumin ('Ortho') or human albumin ('Cutter') added to the saline buffer diluent enhanced the degree of agglutination. The mechanism of the enhancement is being investigated.

Inhibition of the agglutination of sensitized alligator erythrocytes was observed by γ-globulins obtained from ovalbumin rabbit antiserum and by γ-globulin fragments, prepared by Porter's method[8]. Chromatographic fractions (Porter fractions I, II and III) of the rabbit antibody γ-globulins were also tested. Fraction III, at 1·75 mgm./ml., inhibited rheumatoid factor agglutination of sensitized alligator cells. Fraction I, which is reactive with the ovalbumin antigen, did not inhibit rheumatoid factor agglutination at a maximal concentration tested of 4·15 mgm./ml.; neither did fraction II, which is also reactive with ovalbumin antigen, at a concentration of 1·90 mgm./ml. Limited amounts of the globulin fragments were available. Ultracentrifugal examination showed no visible contamination by undegraded whole globulin. The observations indicate that not all globulin fragments are active or equally active as inhibitors of rheumatoid factor hæmagglutination and suggest that there are one or more specific combining sites on the rabbit globulin which interact with the rheumatoid factor(s). In the light of the recent report of Edelman *et al.*[9] of antigenic specificity of 2 human γ-globulin fragments (*F* and *S*) obtained after papain treatment, it might be important to investigate their capacity to combine with rheumatoid factors. The physico-chemical characteristics of globulin fragments which determine inhibitory or lack of inhibitory capacity require further study.

Alligator erythrocytes are found to lend themselves to detection of rheumatoid factor(s) by direct or inhibition hæmagglutination procedures.

We are indebted to the Buffalo Zoo for alligator cells and to Mrs. L. Lipman, Mr. K. Crampton and Mr. Wm. Leumer for technical assistance.

BIOLOGY

Effect of *Iso*nicotinyl Hydrazide on the Path of Carbon in Photosynthesis

IN a study of the pathways of incorporation of carbon-14 from labelled carbon dioxide into the amino-acids glycine and serine during photosynthesis the compound *iso*nicotinyl hydrazide (isoniazid) was used. This compound has been shown to be an inhibitor of transaminases *in vitro* when used at high concentrations (about 10^{-2} *M*)[1,2].

Cells of *Chlorella pyrenoidosa* (Emerson strain) were grown for four days at 25° C. in illuminated culture tanks. 1,200 µl. wet packed volume of cells were suspended in 105 ml. of 10^{-4} *M* potassium dihydrogen phosphate at *p*H 4·5 and the suspension divided into three samples. Isoniazid was added to two of the samples to give concentrations of 10^{-2} *M* and 10^{-3} *M*. The third sample was used as a control. The samples were aerated in the dark for 1 hr. and were then illuminated (light intensity approximately 10,000 lux). Air containing 0·1 per cent carbon dioxide was passed through the suspensions. After 15 min. photosynthesis, 30 µc. of sodium carbonate-^{14}C were added to the suspensions. After a further 10 min. photosynthesis the cells were killed by boiling ethanol. The distribution of carbon-14 among the ethanol-soluble compounds was examined by the procedures of Benson *et al.*[3].

The total fixation of carbon-14 and the distribution of carbon-14 between the ethanol-soluble and ethanol-insoluble fractions is shown in Table 1.

Table 1. CARBON-14 FIXED BY *Chlorella* DURING PHOTOSYNTHESIS (EXPRESSED AS COUNTS PER MIN. PER ML. OF CELLS × 10^{-3}). THE LIMITS OF VARIATION ARE ABOUT ± 5 PER CENT)

	Control	Isoniazid (10^{-3} *M*)	Isoniazid (10^{-2} *M*)
Total fixation	5,340	5,960	5,630
Ethanol soluble fraction	2,978	3,630	3,460
Ethanol insoluble fraction	2,395	2,339	2,157

Isoniazid had only a small effect on the total fixation of carbon-14 and on the distribution between the ethanol-soluble and ethanol-insoluble fractions. There is a slight stimulation of total uptake and carbon-14 content of the ethanol-soluble fraction which is probably significant.

The effect of isoniazid on the distribution of carbon-14 among the compounds of the ethanol-soluble fraction is shown in the histogram of Fig. 1.

The incorporation of carbon-14 into sugar phosphates, phosphoglyceric acid, phosphoenol pyruvic acid, aspartic acid, malic acid, fumaric acid and alanine is considerably reduced by treatment with isoniazid. Incorporation into sucrose is stimulated at the lower concentration and slightly inhibited at the higher concentration. Incorporation into the two-carbon compounds, glycollic acid and glycine, is stimulated about 5- to 8-fold by treatment with 10^{-2} *M* isoniazid and these two compounds account for more than 80 per cent of the total ethanol-soluble carbon-14. Incorporation into serine, which previous evidence suggests is derived from glycine during photosynthesis[4], is inhibited to the same extent as that into sugar phosphates, phosphoglyceric acid, etc. It has been shown by Dac and Wriston[5] that isoniazid inhibits the condensation of formaldehyde and glycine during the formation of serine from sarcosine. Therefore the above results are not necessarily incompatible with the view that serine is derived from glycine during photosynthesis.

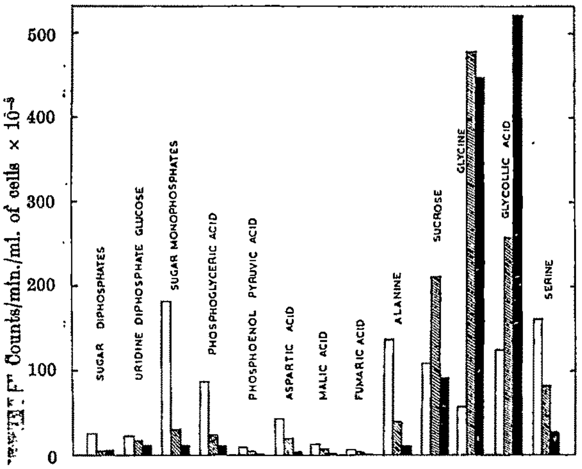

Fig. 1. The effects of treatment of *Chlorella pyrenoidosa* with *iso*nicotinyl hydrazide on the incorporation of carbon-14 into ethanol-soluble compounds during photosynthesis in $^{14}CO_2$. Counts were made directly on-paper chromatograms and have not been corrected for self-absorption. White, control; hatched, 10^{-3} *M* isoniazid; black, 10^{-2} *M* isoniazid

Thus in its effect on the photosynthetic carbon cycle, isoniazid differs from azaserine. The latter substance has been shown to inhibit the transaminases fairly specifically and does not inhibit incorporation of carbon-14 into sugar phosphates and phosphoglyceric acid[6]. The effects of isoniazid on *Chlorella* are similar to those obtained by treatment of *Scenedesmus* with low concentrations of ethanol[7]. Incorporation of carbon-14 into phosphoglyceric acid and sugar phosphates during photosynthesis was inhibited by ethanol treatment while incorporation into glycollic acid and glycine was unaffected or even enhanced. Ethanol, however, inhibited total fixation of carbon-14 quite markedly while in our experiments isoniazid did not. The above results do not indicate specific inhibition of transaminases by isoniazid but suggest a different site of action.

This work is part of a research programme primarily concerned with carbon metabolism in photosynthetic organisms sponsored by the Office of Scientific Research of the Air Research and Development Command, U.S. Air Force through its European Office, under Contract No. *AF* 61(052)-245. The implications of these results will be discussed in a fuller account of this work to be published elsewhere.

Taxonomic Significance of Surface Lipids of Plants

WHILE investigating the composition of surface lipids of plants, we have observed that the chemical composition of the lipid appears to be characteristic of the species of plant. The lipids were extracted from leaves by immersing them for 10 sec. in ether. According to Martin *et al.*[1], and in harmony with our own findings, this treatment does not extract lipids from within the leaf. After removal of the solvent, the residues were chromatographed on thin films of silica supported on glass plates. Three solvents were used for the elution: benzene, benzene containing 5 per cent methanol, and benzene containing 10 per cent methanol. The positions of the components were revealed by spraying separate plates with two reagents: chloroform saturated with

antimony trichloride, and saturated aqueous ferric chloride followed immediately by 0·1 molar sodium molybdate. Both series of plates were heated to 200° C. for 10 min. for full development of the colour. If the plates which were to be sprayed with antimony trichloride were first heated to 200° C. for 10 min. and sprayed while hot, the components showed a large range of colours. Subsequent examination in ultra-violet light showed a less-extensive range of fluorescent colours. Specimen chromatograms in one solvent are shown in Fig. 1.

Although the relative positions occupied by the components are always the same, their R_F values are sufficiently variable to render them of little use in comparing one chromatogram with another. For simplicity, we shall refer to the complete data from six separate chromatograms for each lipid, having regard to the colours of the spots obtained with each spray reagent, and their relative positions when eluted with different solvents, as its pattern. Characteristic patterns were given by each of the surface lipids from 10 species of monocotyledons (*Festuca elatior pratensis S*56 ; *F. ovina* ; *F. rubra genuina S*59 ; *Dactylis glomerata S*143 and *S*26 ; *Phleum pratense S*50 and *S*51 ; *Agrostis tenuis* ; *Alopecurus pratensis* ; *Lolium italicum* ; *L. perenne* ; *Holcus mollis*) and 14 species of dicotyledons (*Rhododendron ponticum* ; *Ilex aquifolium* ; *Fraxinus excelsior* ; *Aesculus hippocastanum* ; *Malus* spp. edible form ; *Rosa* hybrid *H.T.* garden variety ; *Brassica oleracea* sub-sp. *gemmifera* ; *B. oleracea capitata*, red and winningstadt ; *Chrysanthemum* garden variety ; *Antirrhinum majus* cultivated ; *Petunia* spp. ; *Beta vulgaris* (sugar beet type *E*) ; *Trifolium repens S*100).

Before the taxonomic value of the patterns could be considered seriously, three further variables had to be examined : first, it must be established that foliage from different parts of the plant gives the same pattern. For brussels sprout this is certainly true. Lipids from the main leaves and from the outer and inner leaves of the bud all had the same pattern, although the relative concentrations of the components were different, and so too were the weights of lipid per unit area on the inner and outer leaves of the bud.

Secondly, we found that the lipids on the leaf are relatively stable; precisely the same patterns were obtained from freshly cut leaves as from leaves which had been stored for thirteen days. However, once the lipids had been extracted from the leaf, auto-oxidation was detectable by a change in the pattern after the same period.

Thirdly, it was established that the pattern did not change as the plant aged. Waxes from leaves of various ages from *Rhododendron ponticum* and from *Ilex aquifolium* had patterns that were independent of age. Two groups of the 12 grasses were examined; one group had been grown from seed one year before the second group. Once again the patterns were independent of time.

Bate-Smith *et al.*[2] have suggested that the occurrence of tannins in plants may be a useful taxonomic character. Our observations show that a brief qualitative analysis of the surface lipids of plants provides more useful data, even if the identities of the components have not been established.

The technique may be capable of extension to Arthropoda.

We are indebted to Prof. J. B. Speakman, to Miss D. M. Turner for advice and supplies of material, and to the Agricultural Research Council for financial assistance.

Note added in proof. The observations have now been extended to a total of 63 species.

Botryodiplodia theobromae Pat. and *Nigrospora* sp. in the Air of a Jamaican Banana Plantation

Cammack[1] has commented on the lack of detailed information about the composition of the air spora in tropical climates. On the other hand, Hirst[2,3] and others have contributed much to our knowledge of fluctuations in the air spora in a temperate climate. Seasonal changes in three common constituents (*Puccinia polysora*, *Nigrospora sphaerica*, *Cladosporium* spp.) of the air spora of Southern Nigeria have been described by Cammack[1]. The observations described here were made during an investigation[4-6] chiefly designed to provide information about dispersal of *Deightoniella torulosa*, the cause of fruit-spot ('speckle') of Jamaican bananas.

Botryodiplodia theobromae Pat. is a widespread saprophyte and wound-parasite on a considerable range of hosts in the tropics. It is an important parasite of bananas in storage, causing several forms of fruit-rot[7,8]. The pycnospores are elliptical, at first unicellular and hyaline, becoming brown and 1-septate, sometimes with longitudinal striations: dimensions are 20–30 × 10–18μ. There is little risk

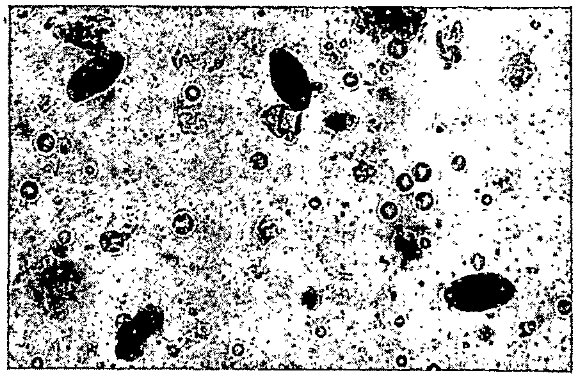

Fig. 1. Relatively large dark-coloured pycnospores of *Botryodiplodia theobromae* from air sampled in a Jamaican banana plantation. (× *c.* 300)

of confusing these spores with those of any other species (Fig. 1). The fungus produces pycnidia on dead or dying banana leaf 'trash', bracts and decaying fruit in the plantation.

A species of *Nigrospora* variously named *N. sphaerica* (Sacc.) Mason[9] or *N. musae* McLennan and Hoette[10] is responsible for the serious 'squirter' disease of banana fruits in Queensland. It is a common saprophyte on banana debris inside the plantation. *N. oryzae* (Berk. and Br.) Petch is also saprophytic on decaying banana tissue. These fungi may be synonymous, and, until further work has been carried out in Jamaica, it is proposed to refer to the fungus discussed here as *Nigrospora* sp. The conidia, which are borne terminally on simple conidiophores, are sub-globose or globose, black and measuring 15 × 18μ or 13–18μ in diameter (Fig. 2).

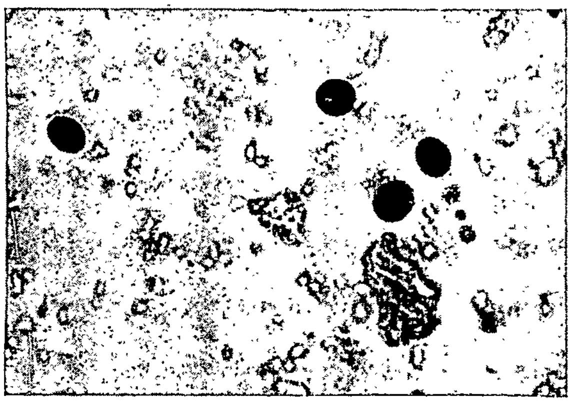

Fig. 2. Sub-globose or globose, black conidia of *Nigrospora* sp. trapped in a banana plantation. (× *c.* 300)

A Hirst spore trap (automatic volumetric) was set up inside a plantation of Lacatan bananas situated on the plains of St. Catherine, Jamaica. The trap orifice was three metres above ground-level. Slides were prepared and mounted in the manner described by Hirst[3], and were changed daily at 09.00 hr. E.S.T. On each slide, traverses 40μ wide and at right angles to the direction of slide movement were scanned at positions representing 2-hourly intervals. The number of spores counted on each cross-traverse was then converted into an estimated number per cubic metre of air. Since no corrections for variation in trapping efficiency were made, all concentrations recorded were under-estimates of the true ones.

The diurnal periodicity curve for *Nigrospora* sp. (Fig. 3) was derived from the geometric means for spore concentration at each even hour, plotted according to Hirst[3]. Also shown are the 2-hourly means for temperature and relative humidity. Each mean was based on counts over sixty-three days (July 19–September 20). The fungus exhibited a well-defined periodicity with peak concentrations occurring near 08.00 hr. each day. After this there was a progressive decrease to a characteristically low night level. This periodicity is similar to that for *D. torulosa*[4], *N. sphaerica*[1], *Phytophthora infestans*[3] and *Polythrincium trifolii*[3,11]. Hirst[3] has suggested that such regularity may be due to the operation of a definite discharge mechanism or to the occurrence each day of environmental conditions favouring spore liberation. Violent spore liberation in *D. torulosa* occurs under conditions of rapidly decreasing vapour pressure[4], usually between 08.00 hr. and 10.00 hr. Webster[12] has described active discharge accompanying drying in *N. sphaerica*, thus helping to explain the periodicity of the fungus in Nigeria. The possibility that a similar process occurs in *Nigrospora* sp. is being investigated.

Variation in absolute numbers of spores of *Nigrospora* sp. appears to be related to rainfall and humidity; highest counts were obtained during predominantly dry weather. The highest 2-hourly estimate recorded so far is 20,000 spores per cubic metre of air at 08.00 hr. There is considerable variation in spore

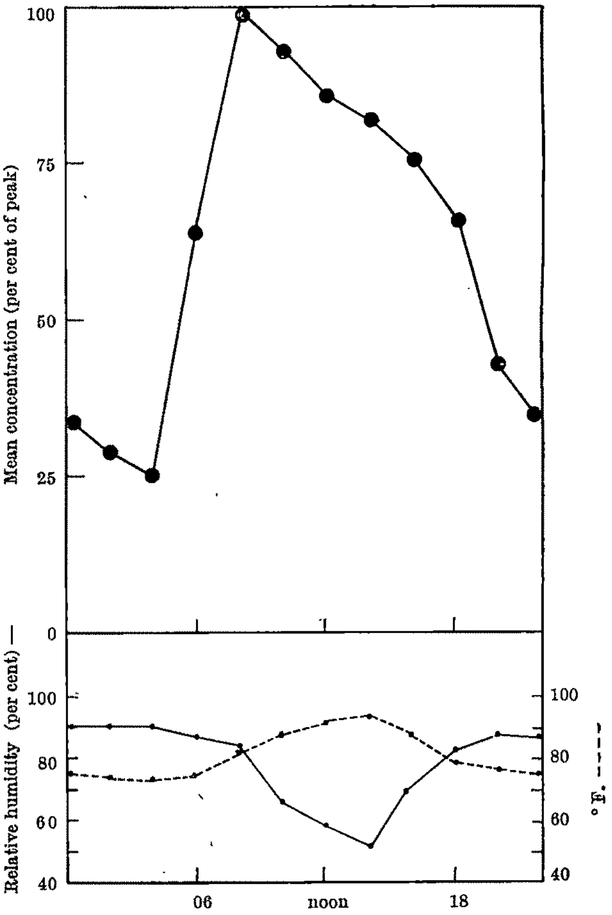

Fig. 3. Mean diurnal periodicity curve for *Nigrospora* sp. in the air of a banana plantation

content between different plantations. Although this will be discussed more fully elsewhere, it seems clear that *Nigrospora* sp. is an extremely common component of the air spora of Jamaican banana plantations.

Because of the small numbers of *B. theobromae* spores trapped, it was not possible to distinguish any clearly defined periodicity. It was, however, unusual to trap spores during the period 20.00–06.00 hr. The highest 2-hourly estimate recorded was 858 spores per cubic metre, when a clump of spores was trapped. The average daily mean concentration throughout the sampling period was only 8 spores per cubic metre. Such meagre counts could not be correlated with fluctuations in weather conditions. It was concluded that this fungus is a relatively infrequent member of the plantation air spora.

Biotin Requirement and Carbon and Sulphur Sources in *Aspergillus* and *Neurospora*

Conidia of the mould *Aspergillus nidulans* were unexpectedly found to require a small amount of biotin (or larger amounts of desthiobiotin) for initial growth, when plated on to a minimal medium of Czapek–Dox, at a density of no more than 10^3 per dish. This fact seems to be in contradiction to what was previously considered to be their basic requirement. Biotin must be added to the minimal medium, for a total germination of wild-type conidia, to the extent of 10^{-6} gm./ml. This corresponds to about 1/100–1/10 of the amount required by the biotinless mutant *bi*-1.

Sometimes a few wild type conidia germinate in the absence of biotin to give rise to normal colonies, the conidia of which, however, have not acquired biotin independence.

When the carbon source (usually glucose 4 per cent) is replaced with an equal concentration (w/v) of fructose, ribose, glycerol or intermediates of the Embden–Meyerhof, of tricarboxylic, or pentose cycle (pyruvate, acetate, succinate, citrate, gluconate) good growth takes place in the absence of biotin. If the glucose is replaced with an equal concentration of sucrose, maltose or dextrin, the basic requirement for biotin is retained. Under our conditions glucose-6-phosphate or glucose-1-phosphate are not utilized as carbon sources (even with added biotin).

Mixtures of glucose and fructose support growth in the absence of biotin, if the amount of fructose is equal or superior to the amount of glucose, whatever the total sugar concentration in a large range (0·2–8 per cent).

A role of biotin in glycolysis, namely as a coenzyme in the hexokinase or in glucose-6-phosphate dehydrogenase systems, was proposed by Moat and Liechstein and Strauss and Moat[2] in biochemical work with *Saccharomyces*. However, this finding was not confirmed by Siepmann and MacDonald[3]. Our results with the carbon sources are compatible with a role of biotin in some initial steps of glucose metabolism.

A variety of nutritional mutants (*ribo*-1, *an*-1, *pro*-1, *paba*-1, *ad*-20, *nic*-2, *lys*-5, *orn*-4) retained the basic biotin requirement of the wild-type, except the parathiotrophic mutant *s*-12, which grew, although with a delay of 24–48 hr., in the absence of biotin. (For description of mutants see Käfer[4].) As this mutant requires reduced sulphur as the only addition in a minimal medium, we looked for a possible effect of the replacement of the source of sulphur on the biotin requirement.

Replacement of 4 m*M* sulphate (which is the only source of sulphur in the Czapek–Dox minimal medium) by an equimolecular concentration of reduced sulphur (sulphite, thiosulphate, sulphide, cystein) or cysteic acid, allows wild-type conidia to give rise to colonies in the absence of biotin, though growth is delayed 24–48 hr. Addition of biotin ($2\cdot5 \times 10^{-9}$ m*M*) restores the growth to a normal rate.

Methionine, which is utilized in the presence of biotin as a reduced sulphur source by the parathiotrophic mutant, does not support growth in the absence of biotin. Moreover, the methionineless mutant *meth*-1 retains the biotin requirement of the wild-type.

A wild-type strain of *Neurospora crassa*, commonly regarded as a biotin-requiring mould, is able to grow in the absence of biotin if glucose is replaced by fructose, or sulphate by sulphide, on the same Czapek–Dox minimal medium. In the latter case, growth is improved by the addition of biotin.

Many species of moulds are reported to need biotin[5]. It would be of interest to elucidate the mechanism of this requirement, which appears to be similar in *Aspergillus* and *Neurospora*.

This work was aided by a grant to one of us (P. S.) from the Comitato Nazionale per l'Energia Nucleare.

Transfer of Ova to the Bursa Ovarii and the 'Suspended Loop' of Tube in the Rabbit

In mammalian species successful ova transfer is possible when the ova are replaced inside the Fallopian tubes or uteri of laparotomized synchronous recipients. In species with confined bursa ovarii, like the mouse, the ova can be transferred into the fat pad adjacent to the bursa ovarii, through the capsular membrane and into the bursa proper[1]. Intravaginal ova transfer was not successful in cattle[2], owing

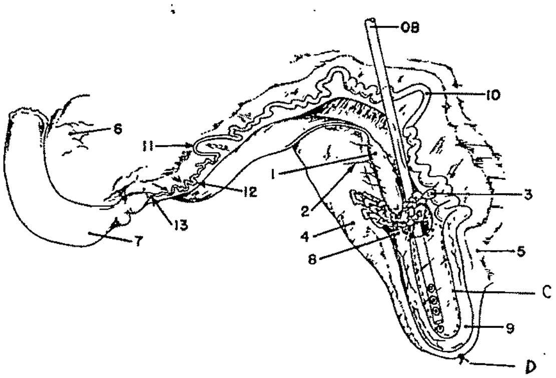

Fig. 1. Diagram of experimental treatments; removal of membrane of bursa ovarii (*C*), induced adhesions in suspended loop (*D*) and ova transfer to ovarian bursa (*OB*). 1, ovary; 2, ovarian artery and vein; 3, appendix vesiculosa; 4, mesosalpinx; 5, suspended mesosalpinx; 6, broad ligament; 7, uterus; 8, infundibulum; 9, suspended loop (ampulla); 10, embedded ampulla; 11, major loops (isthmus); 12, minor loops (isthmus); 13, uterotubal junction (intramural sphincter)

to increased sensitivity to bacterial infection and pyometra during the luteal phase[3]. A few cases of intravaginal ova transfer in the rabbit were successful when antibiotics were used[4]. Intraperitoneal insemination has been successful in several species such as the rabbit[5], guinea pig[6,7], cattle[8], pigeon and hen[9]. Intraperitoneal ova transfer has not been possible yet.

The tubo-ovarian anatomical relationships are of some importance for the reception of ova. The ampulla of the tube is not held in position, but it forms a loop *suspended* in the pelvic cavity (Fig. 1). This loop is attached to a thin fold of the peritoneum which is connected to the mesosalpinx. This thin fold, together with the fatty pad attached to the suspended loop, makes the ovarian bursa. The transit of the ovum from the ruptured follicle to the uterotubal junction is ensured by two series of complex processes; mechanisms for 'reception' or 'adjustment' and mechanisms for tubal 'transportation'.

This work was undertaken to evaluate the physiological significance of suspended loop in ova reception and the possibility of transfer of ova in the ovarian bursa of the rabbit.

Exp. 1: Seven adult does were laparotomized on both sides and the Fallopian tubes exposed. On one side, the membrane attached to the suspended loop of the ampulla (which is part of the ovarian bursa) was removed by fine scissors (Fig. 1). The does were allowed 3 days to recover from the operation, then mated (with or without superovulation) to fertile bucks and killed 40, 50 and 98 hr. *post coitum.* The ampulla, isthmus and uterus were dissected and flushed separately with saline. The ova were examined microscopically. The diameter of blastocysts was measured.

Exp. 2: Twenty donors were superovulated, mated to fertile bucks, killed 16–40 hr. *post coitum,* and the ova were flushed out. The healthy ova were transferred to twenty synchronous pseudopregnant recipients. In one side of the recipient, the ova were transferred to the bursa ovarii (Fig. 1). In the other side, the ova were transferred at different parts of the tube. The recipients were either killed 2, 3 or 4 days *post coitum,* or laparotomized 8 days *post coitum.* When killed, the reproductive tract was dissected and the ampulla, isthmus and uterus flushed separately. The flushings of each portion were examined microscopically. Pregnant recipients were allowed to proceed to term.

Exp. 1: When the membrane of the bursa ovarii was removed, the reception and transportation of the ova in the tube were not affected. The number of ova recovered corresponded to the number of ovulation points, that is, there was no loss of ova. In two cases, however, 11 and 33 per cent of the ova shed were not recovered in the flushings. This could not be ascribed only to faults of flushing or manipulation. It may have been due to the loss of ova in the peritoneal cavity through the fimbriated end of the tube or to the absence of ova in the follicles.

When the suspended loop was attached to the mesosalpinx, the transportation of ova from the ampulla to the uterus was normal. Ova reception was affected and ova loss increased, ranging from 13 to 33 per cent of ova shed. This may be due to the adhesions which were induced by the experimental treatment. It is possible that the pendulous structure of the suspended loop helps in the reception of the ova.

There were no significant differences between the size of blastocysts in the two experimental treatments. There were wide individual variations in the intrazonal diameters and outside diameters of blastocysts. This may be partly due to differences in the cleavage-rate of fertilized ova in the same animal.

Exp. 2: When 1-cell fertilized ova were transferred to the ovarian bursa, ova pick-up by the fimbria occurred in 57 per cent of the cases. The percentage of transferred ova picked up varied from 0 to 35, with an average of 10. The rate of passage of the alien ova was similar to that of the recipient's own native unfertilized ova. This may indicate that the ova were picked up from the ovarian bursa in a relatively short time. The ova which were transferred to the ovarian bursa had normal subsequent development and implantation. The young delivered were also normal.

When 8–16-cell ova were transferred into the ovarian bursa of synchronous recipients, ova pick-up was recorded in 88 per cent of the cases. The percentage of transferred ova which were picked up varied from 0 to 25 with an average of 12. When the 1-cell or 8–16-cell ova were transferred to different parts of the tube, the percentage ova pick-up ranged from 41 to 44 with an average of 42. Ova were not picked up when transferred to the peritoneal cavity very close to the fimbria in 1-day pseudo-pregnant recipients (Hafez, unpublished work).

The present work and other comparative investigations have elucidated, to a certain degree, the physiological importance of the tubo-ovarian anatomic arrangement. The physiological significance of the suspended loop of the tube is not exactly known. It may be the agency by which the ovum is transported rapidly in this portion of the tube, as compared with the rate of ovum transport of the isthmus. The relative physiological significance of such anatomical structure in other species is also of academic significance.

Apparently, the membrane attached to the suspended loop which makes the ovarian bursa was of little importance in reception of ova. Adhesions induced in the suspended loop increased the percentage of ova lost in the peritoneal cavity. The fimbria was able to pick up 1-cell or 8–16-cell ova if transferred to the bursa ovarii of synchronous recipients. The percentage pickup was lower than when ova were transferred to the tube. Detailed results of this work will appear elsewhere.

This investigation was supported by grants from the Population Council, Inc. (3031), and the National Science Foundation (*G* 9938). Thanks are due to the Ayerst, Squibb and Wyeth Institute for donations of hormones.

Seal Tracks in the Taylor Dry Valley

The mummified carcasses of the crab-eater seal (*Lobodon carcinophagus*) are found in many places in the ice-free regions around McMurdo Sound in the Ross Dependency, Antarctica[1]. All these carcasses appear to be old. Some have only fragments of tissue on the bones, but others, although desiccated and wind blasted, are well preserved. One carcass has been dated[1] giving an age of 1,600–2,600 yr.

During a soil survey in the summer of 1959 of the Taylor Dry Valley I observed many carcasses, probably including a number of those observed by Scott[2], Griffith Taylor[3] and Péwé's party[1]. Most of these carcasses also appeared to be old, wind blasted and in some cases only scattered bones were observed. Three carcasses were observed on the ice of Lake Bonney at the western end of the Dry Valley although more were observed on the ice of other lakes in the Valley. It is difficult to estimate the age of the carcasses, because of the very low rate of organic decomposition in the arid, cold climate of the valley, but casual observation leads to the conclusion that most of the carcasses are of similar age—probably as old as the carcass the age of which was determined by Péwé *et al.*[1]. However, on a small alluvial plain at the eastern end of a large lake in the Taylor Valley, the track of a seal was observed. This was a furrow in the sand, about 1 in. deep and 6 in. wide, following an irregular course across the plain. It showed flipper marks and places where the seal had rested, and changed direction. Similar tracks were observed on beaches at Cape Evans and Cape Royds. The track disappeared under snow-drifts at either end, so that it must have been made before the winter of 1959. The Valley has been visited many times in the past few years, and footprints, helicopter wheel impressions and other traces of human activity are quite common, including some that must have been made during the autumn of 1956, when a meteorological station in the Valley was occupied. This means that such minor impressions are not removed rapidly by climatic influences and persist for at least 5 yr. Judging by the state of preservation of the track and comparing it with footprints in the neighbourhood, the track appears to be less than 5 yr. old. A search was made for the seal, but it was not found. A lake was not far distant, and the seal could have reached it and entered the water at the thaw-moat that appears during the summer.

The site where the tracks were observed lies about 6 miles from the coast, and the intervening country is covered with ridges of moraine several hundred feet high. During the summer period the ground was bare except for occasional small patches of snow.

No seals have been observed in the act of crawling inland. If all the carcasses are of similar age, as they appear to be, then the conditions that cause seals to move inland may have existed at some time about 2,000 yr. ago and the presence of seals on any land surface must mean that the surface is older than about 2,000 yr. However, if the track observed indicates that seals do still travel inland occasionally, then the age of each carcass must be measured to determine a minimum age for the land-form. Observations in the Taylor Valley seem to indicate a rather complicated history of ice-movements. Some figures on the age of land-forms may help to sort out this history.

If the twenty or so carcasses observed in the Taylor Valley represent all the seals that have travelled up the Valley in the past 2,000 yr. and that there has been the same tendency to wander inland during this period, then the rate is approximately one every hundred years. Even if more carcasses are present, but not observed, and if others have crawled into moats at the edges of frozen lakes, then the rate is still very low. The carcass dated by Péwé *et al.* may not be the oldest in the Valley and the rate would then be still slower. It is possible that carcasses of seals dehydrate rapidly in the arid climate and after a short period reach a stage of decay which does not proceed further, and thus all observed carcasses appear of similar age.

ENTOMOLOGY

Resistance to Dieldrin in *Anopheles* in Trinidad

Dieldrin has been in use as a larvicide against *Anopheles neomaculipalpus* Curry for several years in the Piarco Airport area of Trinidad. This species is of secondary importance to *Anopheles aquasalis* as a vector of malaria in the coastal areas of the Colony.

Lack of proper control recently in the Piarco area raised suspicions that the species was showing some degree of resistance to dieldrin. Susceptibility tests with the standard World Health Organization mosquito adult test kit using freshly blooded wild-caught specimens taken from calf-baited Shannon dawn traps gave the results with DDT and dieldrin shown in Table 1.

It is to be noted that about 27 per cent of the mosquitoes tested survived 1·6 per cent dieldrin papers for 8 hr. and there was a 5 per cent survival

Table 1. *Anopheles neomaculipalpus* CURRY. LOCALITY: PIARCO AIRPORT AREA, TRINIDAD.

Date of test 1960	No. of tubes	Concentration (per cent)	Exposure time (hr.)	No. of mosquitoes tested	Dead (per cent)	Control

December 14–17	5	Dieldrin, 4·0	1 hr.	90	84·9	26	0
			Dieldrin, 1960				
August 15–17	4	Dieldrin, 1·6	1 hr.	99	35·3	25	4
August 12–13	4	Dieldrin, 1·6	2 hr.	101	43·5	26	0
August 11–12	4	Dieldrin, 1·6	4 hr.	102	63·7	25	0
August 10	4	Dieldrin, 1·6	8 hr.	103	72·8	25	8
August 23–26	4	Dieldrin, 4·0	1 hr.	95	85·3	25	0
August 25–30	4	Dieldrin, 4·0	8 hr.	105	95·1	24	0

even after 8 hr. exposure to 4 per cent dieldrin papers, indicating that the species is clearly resistant to dieldrin.

The tests with DDT show that despite DDT residual house spraying for several years in the nearby villages for malaria control, the species is still susceptible to this insecticide. The LD_{50} as determined on logarithmic-probability graph paper is about 0·8 per cent DDT.

This is the second anopheline to show resistance to dieldrin in Trinidad, the other being *Anopheles aquasalis*, which was first shown to be resistant in 1958.

A Differentiation Centre in the Embryo of *Dacus tryoni*

IN several insects the cells of the embryonic blastoderm have been shown to depend for their further development on a stimulus emanating from a ventral prothoracic differentiation centre[1,2]. In cyclorrhaphous Diptera a similar centre has so far escaped detection, although Yao[3] has proposed one for *Drosophila melanogaster* on the basis that alkaline phosphatase activity is first detectable in the ventral prothoracic region during contraction of the germ band and spreads both anteriorly and posteriorly as histo-differentiation proceeds. Further results bearing on this question have now been obtained by the application of ligatures to the early embryos of *Dacus tryoni* (Diptera, Trypetidae (= Tephritidae)).

Methods for maintaining breeding stocks of *D. tryoni* in the laboratory are described by Bateman[4]. Development of the eggs, an account of which will be published in due course, follows the typical dipteran pattern, with cleavage leading to the formation of a blastoderm by 7½ hr. at 25° C. and subsequent gastrulation, elongation and shortening of the germ band, involution of the head and completion of histo-differentiation resulting in hatching at 42–48 hr.

In the present work nine batches of 20 eggs were used. In each batch 10 eggs were set aside as controls, and the remaining 10 identically ligatured at a known time after oviposition. Three batches were treated at 2–3 hr. (cleavage nuclei invading the cortex), three at 4½–5½ hr. (syncytial blastoderm) and three at 6–7 hr. (cellular blastoderm). For each the ligatures were so placed as to separate, in the first batch, the anterior third of the embryo from the posterior two-thirds, in the second, anterior and posterior halves and in the third, the anterior two-thirds from the posterior third. The eggs were then allowed to develop until the normal time of hatching and examined after removal of the chorion by immersion for 30 sec. in a commercial solution of sodium hypochlorite.

Control eggs developed normally. Of the ligatured eggs, approximately half of each batch was incompletely divided by the ligature, the two parts of the embryo being joined by a narrow neck. Development in these also proceeded normally. Where successful ligature completely separated the two parts, however, the following observations were made:

(*a*) Ligature at 2–3 hr. at the border of the anterior third resulted in normal development of the posterior two-thirds, but in cessation of development of the anterior third at the blastoderm stage. Ligature at or behind the equator at this time, conversely, allowed normal development of the anterior part. but caused cessation of development of the posterior part at the blastoderm stage.

(*b*) Ligature at 4½–5½ hr. either at the border of the anterior third or at the equator had no effect on the development of either part of the embryo, but ligature at the border of the posterior third again caused cessation of development of the posterior part at the blastoderm stage.

(*c*) Ligature at 6–7 hr. allowed both parts of the embryo to develop normally, irrespective of the position of the constriction.

It can be concluded, therefore, that a differentiation centre lying between the border of the anterior third and the equator of the egg begins to produce at 3 hr. after oviposition a stimulus, presumably chemical, essential to the further development of the blastoderm, and that the stimulus spreads both forwards and backwards, reaching beyond the equator of the egg by 4½ hr. and into the posterior third by 6 hr. Descriptive studies confirm that the site of the differentiation centre is the prothoracic segment, as in other insects, and also reveal that subsequent major events in gastrulation begin at this point. Further investigations are now being pursued to localize the differentiation centre of *D. tryoni* more precisely.

The present work also confirms that determination in the cyclorrhaphan egg is completed at a very early stage[5,6], since none of the developing parts here separated by ligature showed regulation.

Distribution of *Acarapis woodi* (Rennie)

Mites determined as *Acarapis woodi* (Rennie) were found recently on one of the escorts with a queen bee (*Apis mellifera* L.) from California. This suggested a wider distribution than previously recorded, and a survey of commercial apiaries in Queensland was commenced. The mite is widely spread on bees in this State.

In the meantime *A. woodi* was found on bees from other American States, New Zealand, and also from Italy.

These findings certainly extend the known distribution of the species.

Numerical Regulation of Populations of the Codling Moth, *Cydia pomonella* (L.)

The numerical regulation of the codling moth has been investigated in the Australian Capital Territory. Each year, part of the population undergoes two complete generations and begins a third, most individuals of which fail to survive. The other part of the population enters diapause, and the species overwinters as mature, diapausing larvæ produced mainly in the second generation.

The level of infestation is always very high in unsprayed orchards, irrespective of size of crop. It was found that the pest multiplies each year to densities which are limited by the supply of larval food, that is, pome fruits, particularly apples.

The extreme suitability of the local environment for codling moth is determined by: (1) a very long season, extending from mid-October to late March, during which weather conditions are almost continuously favourable; (2) the extensive use of a very late maturing apple variety (Granny Smith); and (3) the absence of effective antagonists.

Intraspecific competition both for larval food and for cocoon shelter is the essential mechanism for numerical adjustment of the species in this environment.

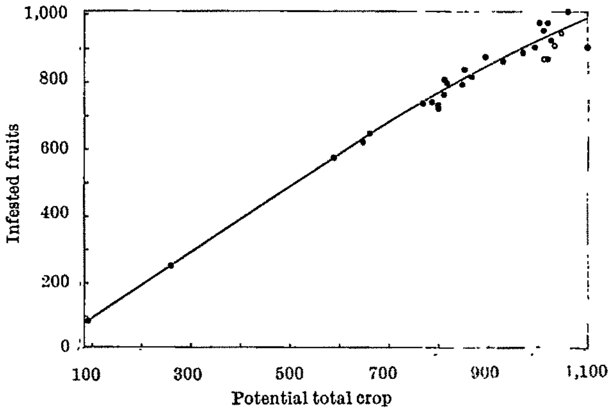

Fig. 1. Relationship between the potential number of fruits and the number of fruits penetrated by codling moth per tree. Dots, observed values; line, calculated values

It is known that larvæ may feed successively in several fruits, and that several larvæ may develop from the same fruit. However, these occurrences are exceptional. In general, only one individual survives after simultaneous infestation of the same fruit by several larvæ and one mature larva is produced for almost every infested fruit. Competition for larval food is thus a form of contest[1].

In a homogeneous plot of twenty-nine apple bushes, the relation between the potential total crop and the number of penetrated fruits per tree was described satisfactorily by the equation:

$$Y = X\left(1 - e^{-\frac{N}{X}}\right)$$

where Y is observed number of penetrated fruits per tree; X is potential number of fruits per tree (estimated from total numbers of fruit buds in spring); N is number of penetrations per tree (Fig. 1).

This equation is a variant of that used by Nicholson and Bailey[2] to describe random searching. Random search implies that all fruits are equally liable to penetration and that newly hatched larvæ are incapable of avoiding fruits which are already infested or otherwise unsuitable as food. This lack of discrimination intensified contest as population density increases, and makes complete infestation of a crop improbable. Furthermore, the equation postulates that the number of penetrations is similar on all trees of the plot irrespective of size of crop. This does in fact occur when the trees provide a comparable supply of cocoon shelter.

Larval development is completed in the fifth instar. Mature larvæ leave the fruits and seek sites in which to spin a cocoon and pupate. Whereas non-diapausing larvæ are often content to spin a flimsy cocoon in very poor shelter, overwintering individuals search their environment intensively for favourable sites. These occur mainly on the trees, under loose bark and in cracks, wounds and debris. However abundant such sites may be, they are not as a rule found easily by larvæ. Many larvæ fail completely to find adequate shelter and are lost, usually by predation. The favourable overwintering sites are potentially accessible to the remainder, some of which are successful and establish their hibernacula, while the others are eliminated by competition. This competition is also a form of contest. Except when the density of diapausing larvæ is extremely high, it is less intense than contest for larval food.

The very high levels of crop infestation which prevail in unsprayed orchards can result from remarkably small populations of overwintering larvæ, often no more than ten individuals per mature tree. These populations do not vary much from year to year, because the amount of cocoon shelter available remains fairly constant. Any variations which do arise in overwintering populations, following fluctuations in the size of the preceding crop, are damped by the contest for larval food resulting from random searching. Very dense populations in the early summer are thus prevented from destroying the fruit crop prematurely, and, consequently, from suppressing completely the diapausing larvæ which are produced later in the season. In this way, codling moth populations can very nearly exhaust their seasonal supply of larval food each year without the risk of attaining self-destructive densities.

The principal density-governing factor regulating codling moth abundance is the availability of previously uninfested fruits to newly hatched larvæ. The availability of favourable shelter to diapausing larvæ acts as a complementary governing factor[3].

MacLellan's[4] work on the destruction of overwintering codling moth populations by woodpeckers in eastern Canada and the resulting low levels of summer infestation suggests that similar effects could be achieved in Australia in a different way, namely, by bringing cocoon shelter into very short supply. For this to be effective, cocoon shelter would have to be reduced to such an extent that it became the principal governing factor in the numerical regulation of codling moth. Experiments are in progress to test the feasibility of this approach for Australian conditions.

The help obtained from Mr. G. A. McIntyre, in the Division of Mathematical Statistics of this Organization, is gratefully acknowledged.

BACTERIOLOGY

Aspects of the Conversion of Glucose to α-Ketoglutarate in *Acetobacter melanogenum*

GLUCOSE oxidation in extracts of *Acetobacter melanogenum* has been shown to result in the formation of pyruvate[1] through reactions involving the pentose phosphate cycle and the Entner–Doudoroff splitting reaction[2]; glucose is also oxidized to 2,5-diketogluconate[3] and then to α-ketoglutarate[4]. In a previous paper[5], evidence was given for the functioning of only certain portions of the tricarboxylic acid cycle in *A. melanogenum*. It was also shown that these cells did not synthesize four carbon compounds from one-, two- or three-carbon precursors. It was, therefore, of interest to study the contribution of the various pathways in the synthesis of α-ketoglutarate from glucose in washed cell suspensions of *A. melanogenum*.

The isolation and assay of radioactive compounds and methods of preparing washed cell suspensions have been described[5]. Cells oxidizing specifically labelled glucose-^{14}C release amounts of $^{14}CO_2$ which differ according to the position of the labelled carbon (Table 1). The $^{14}CO_2$ values are consistent with the operation of a pentose phosphate cycle, Entner–Doudoroff splitting reaction and part of the glycolytic pathway[1]. Dinitrophenol almost completely inhibits the release of $^{14}CO_2$ from the differently labelled ^{14}C-glucose (Table 1), whereas the oxygen uptake in this experiment is only inhibited to the extent of 22 per cent. These results indicate a dichotomy in the oxidative degradation of glucose. As dinitrophenol is an inhibitor of oxidative phosphorylation[6], its presence decreases the supply of adenosine triphosphate necessary for the breakdown of glucose by enzymes of the phosphorylated pathways. This results in nearly maximal inhibition of the conversion of glucose-^{14}C to $^{14}CO_2$. The small amount of $^{14}CO_2$ released in the presence of dinitrophenol may be due to endogenous supplies of adenosine triphosphate regenerated by glycolytic enzymes and to the conversion of glucose to 2,5-diketogluconate, followed by its slow decarboxylation[7] with the eventual formation of α-ketoglutarate[4]. The latter sequence of reactions is not inhibited by dinitrophenol in extracts of *A. melanogenum*[4], and seems to be the main route of oxygen uptake during glucose oxidation by cells.

Table 1. EFFECT OF DINITROPHENOL ON THE OXIDATION OF GLUCOSE-1-, -2-, -6-^{14}C AND -U-^{14}C BY *A. melanogenum*

System	$^{14}CO_2$ formed (counts per min.) Dinitrophenol absent	Dinitrophenol present	Inhibition due to dinitrophenol (per cent)
Glucose-1-^{14}C	14,650	710	95
Glucose-2-^{14}C	6,330	140	98
Glucose-6-^{14}C	7,420	400	95
Glucose-U-^{14}C*	12,690	210	98

* Uniformly labelled glucose.

Components of reaction mixtures in 2·4 ml.: potassium phosphate buffer, *p*H 7·4, 120 μmoles; ^{14}C-labelled glucoses, 10 μmoles. (20,000 c.p.m./μmoles); dinitrophenol, 12 μmoles; cells, 0·8 gm. wet weight. Duration of experiment, 10 min. Temperature, 30° C.

Cells oxidizing glucose-U-^{14}C rapidly incorporate radioactivity into α-ketoglutarate as compared with pyruvate (Fig. 1). The specific activity of α-ketoglutarate reaches a maximum value which is similar to that obtained on a theoretical basis, assuming that it is formed from glucose with the loss of one carbon atom. It is interesting that the specific activity of pyruvate is low. This may be due to non-equilibration of the pyruvate pool with radioactive pyruvate, a phenomenon which has been demonstrated[5] when *A. melanogenum* cells were incubated with pyruvate-2-^{14}C.

Fluoroacetate (3×10^{-3} *M*) and dinitrophenol (5×10^{-3} *M*) had no effect on the kinetics of formation of radioactive α-ketoglutarate and pyruvate (Fig. 1). Fluoroacetate is known to inhibit aconitase in animal

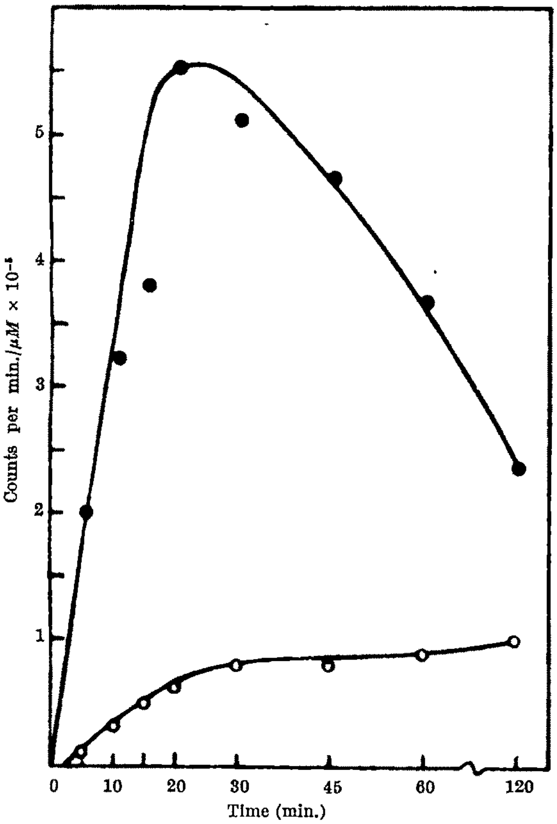

Fig. 1. Variation with time of the specific activities of α-ketoglutarate (—●—) and pyruvate (—○—) formed from glucose-U-^{14}C by resting cell suspensions. Reaction mixture contained in 10 ml.: potassium phosphate buffer, *p*H 7·4, 500 μmoles; glucose-U-^{14}C, 15 μmoles (666,000 counts per min./μmole); cells, 3·3 gm. wet weight. Temperature 30° C.

tissues[8]. In *A. melanogenum* its use results in a two-fold increase of radioactive citrate in cells oxidizing acetate-1-^{14}C.

From the results of these experiments, the conclusion may be drawn that α-ketoglutarate is formed in washed cell suspensions of *A. melanogenum* by the pathway involving non-phosphorylated intermediates (that is, gluconate and 2,5-diketogluconate[3,4]). This synthetic route is also consistent with the observations[5] on the lack of synthetic enzymes for the net formation of α-ketoglutarate from pyruvate in the tricarboxylic acid cycle.

I wish to thank Dr. R. M. Hochster, in whose laboratory in the Microbiology Research Institute, Department of Agriculture, Ottawa, Canada, the major part of this work was carried out, while I held a postdoctoral fellowship of the National Research Council of Canada.

Folinic Acid Requirement of Strains of the Genus *Pediococcus*

Until some ten years ago, the genus *Pediococcus* was recognized only in the brewing industry, but strains of *Pediococcus cerevisiae* are now known to occur commonly in other food products[1,2]. It has been suggested that strains of the genus isolated earlier were not always correctly identified, and were classified as either leuconostocs or micrococci, according to their catalase reaction[3]. Therefore, any test which would help to identify the genus or the species *Pediococcus cerevisiae* would be useful. Felton and Niven[4] suggested that a requirement for folinic acid might be a generic character of the pediococci. However, they examined only typical strains of *Pediococcus cerevisiae* and, while it is true that a majority have this requirement, strains without it are known[5].

Recently four strains of *Pediococci* (*N.C.D.O.* 1247, 1248, 1249 and 1250; that is, *L*354, *S*190, *L*22 and *S*344 respectively) were deposited in the National Collection of Dairy Organisms by Dr. H. L. I. Gunther, of Queen Elizabeth College, University of London, and these were reported to vary in several respects from the typical *Pediococcus cerevisiae*[6].

They were therefore examined for their folinic acid requirement in the synthetic medium used for the assay of folinic acid with *Pediococcus cerevisiae* *ATCC* 8081[7]. All four strains failed to grow even when folinic acid was present, and under conditions which supported normal growth of *ATCC* 8081. It was found that certain additions to the assay medium and sometimes modified cultural conditions were necessary before all the strains would grow.

The strains were sub-cultured in tomato glucose broth in which three of them, *N.C.D.O.* 1247, 1248 and 1249, grew well aerobically and also anaerobically. The fourth strain, *N.C.D.O.* 1250, failed to grow except under anaerobic or reducing conditions, and good growth of this strain has not been obtained aerobically in any medium. Therefore, for *N.C.D.O.* 1250, 0·5 ml. of a 1 per cent w/v solution of ascorbic acid, sterilized by Seitz filtration, was added to each 10 ml. of medium before inoculation, and the tubes incubated aerobically.

'Tween 80', an ingredient of the tomato glucose broth, was found to be essential for the growth of all four strains, although Kitay and Snell[8] found that *ATCC* 8081 did not require it. Two of the strains, *N.C.D.O.* 1247 and 1250, grew well when 'Tween 80' (0·001 ml./10 ml.) was added to the Sauberlich and Baumann medium containing folinic acid.

Charcoal-treated tryptic digest of casein solution was prepared according to Roberts and Snell[9] and added to the assay medium, at a level of 1 ml./10 ml. Under these conditions all the strains grew well. It appears that, as with other strains within the Lactobacilliaceae[10], *N.C.D.O.* 1248 and 1249 require a peptide in addition to the amino-acids and other growth factors supplied.

A solution containing vitamin-free acid-hydrolysed casein, tryptophan, phenylalanine, histidine, tyrosine and cystine could replace the amino-acid mixture in the original medium, but the addition of the tryptic digest of casein was still necessary.

The folinic acid requirement of the strains was examined in this modified medium, adding only one level, 0·1 μgm./10 ml. The composition of the medium and the techniques used for the growth tests have been described by Garvie, Gregory and Mabbitt[11]. Since a variety of strains and possibly more than one species were being examined, the growth of each strain was observed after 24- and 48-hr. incubation at 30° C. in the medium with and without folinic acid. Two of the strains, *N.C.D.O.* 1250 and 1247, grew equally well in all tubes and had no requirement for folinic acid. The other strains, *N.C.D.O.* 1248 and *N.C.D.O.* 1249, gave excellent growth in the presence of folinic acid at 24 hr., but none in its absence. However, at 48 hr. in the absence of folinic acid, growth sometimes occurred. Thus, with these strains, folinic acid has a marked stimulatory effect on growth, although under conditions at present undefined, they grew in its absence, but only after a prolonged lag phase. The control, *ATCC* 8081, showed no growth in the absence of folinic acid after 48 hr. incubation.

These results show that a requirement for folinic acid is not restricted to typical strains of *Pediococcus cerevisiae*. Until more strains have been examined, it is not possible to decide if the growth requirements which have been discussed are useful in classification, or if they demonstrate merely variations within the species *Pediococcus cerevisiae*.

A Bacteriophage for Motile Bacteria

IN the first stage of phage infection, the phage particle is adsorbed to a specific receptor which is usually on the bacterial body[1]. However, an exceptional phage has been reported[2] the host-range of which appeared to be determined by flagella, and these are structurally distinct from the bacterial surface proper[3].

Four conditions have now been found to determine bacterial sensitivity to this *Salmonella* phage, named χ.

(1) The bacteria must be flagellated. Non-flagellated strains are invariably resistant, and resistant non-flagellated variants are selected from sensitive strains by the phage.

(2) The flagella must carry certain antigens. Sensitivity was shown to depend on the flagellar (H) antigen, and not on the somatic (O) antigen, by tests on (a) 524 naturally occurring motile *Salmonella* strains belonging to 27 different O groups and carrying most of the known H antigens; and (b) sets of artificial derivatives of single strains, differing in their H antigens, which had been prepared by phage-mediated transduction[4]. Strains with most H antigens could be sensitive, but all 53 naturally occurring strains with antigens of the g complex (g,m, g,p, g,s,t, etc.) were resistant: transduction of antigen g . . . to sensitive strains made them resistant, and resistant strains naturally carrying g . . . were often sensitive when another antigen was substituted. The wild-type phage did not attack strains with H antigen l . . . (l,z_{13}, l,v, or l,w), but could mutate to a form able to do so. Host-range mutants were also isolated for bacteria with H antigens e,h and Arizona 13. Diphasic strains carrying g . . . , l . . . or e,h in one phase could be sensitive to wild-type phage in the alternate phase.

(3) The flagella must be active: 10/10 naturally occurring paralysed (that is, flagellated but non-motile) strains were resistant while their motile derivatives were sensitive. Also, 8/80 resistant variants selected by the χ phage from sensitive strains turned out to be paralysed. Reversion to motility was accompanied by return of sensitivity.

(4) The bacterial strain itself must be suitable, for not all motile bacteria with appropriate H antigens were sensitive. The importance of the bacterial strain was clearly seen with transduction of an antigen, for the strain from which the antigen had been transduced often reacted differently from the recipient.

Resistance due to absent or inactive flagella, or to flagella of inappropriate antigenic type, could be shown to be associated with impaired adsorption of the phage, by using sets of variants of suitable strains. Adsorption was prevented by detaching the flagella from sensitive bacteria, and returned progressively to normal as the flagella were regenerated. Adsorption was also impaired when sensitive bacteria were artificially paralysed by treatments such as thorough washing, or exposure to 2,4-dinitrophenol.

No adsorption to detached flagella was detected, probably because they were inactive.

Electron micrographs, kindly prepared by Mrs. H. Ozeki and by Dr. E. H. Mercer, showed phage particles attached by the tips of their tails all along the length of the flagella; none was seen on flagella carrying antigens associated with resistance and few or none were found on paralysed bacteria. Other experiments showed that infection could follow adsorption to distal as well as proximal parts of a flagellum.

If, as it appears, isolated[5] and paralysed[6] flagella are structurally similar to active flagella, then the latter do not seem to possess any unique structure that might be the phage receptor. The necessity for flagellar movement to promote phage infection may thus mean that the activity is necessary in itself and not merely a concomitant of a new flagellar structure. The means by which the phage genome passes from its primary site of adsorption on a flagellum to the bacterial body is not clear, but the flagella do not seem to act merely by 'activating' the phage so that it can attach itself to the bacterial body afterwards. These points and the detailed results are discussed elsewhere.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 8

University of London (at the Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2), at 5 p.m.—Dr. S. Brenner: "Bacteriophage Growth".*

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. A. Neuberger, F.R.S.: "The Biosynthesis of Porphyrins and Chlorophylls".* (Further lecture on May 11.)

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Scientific Papers.

University of London (at the School of Pharmacy, 29–39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. L. W. Busse (Wisconsin): "Some Aspects of Percutaneous Absorption".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Basil Taylor: "The Presentation of Visual Arts". (Second of three Cantor Lectures on "The Presentation of Science and the Arts on Television".)

Royal Aeronautical Society, Historical Group (at 4 Hamilton Place, London, W.1), at 7 p.m.—"A Quiz on Little Known Early Aircraft".

Tuesday, May 9

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Annual General Meeting, followed by a full-day Meeting on "Manuring of Tropical Crops".

Aslib (in the Lecture Theatre of the Royal Aeronautical Society, 4 Hamilton Place, London, W.1), at 2.30 p.m.—Discussion on "The National Reference Library of Science and Invention".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

University of London (at the School of Pharmacy, 29–39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. L. W. Busse: "Electronic Analysis of Emulsion Globules".*

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. M. E. Burt: "Structural Weight Estimations for Novel Configurations".

Wednesday, May 10

University of London (in Lecture Room 102, Chemical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 4 p.m.—Prof. Gabriel Stein: "Recent Advances in the Radiation Chemistry of Aqueous Systems—Part II, Some Systems of Biochemical Interest".*

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. M. Datta: "Electricity Supply in India and its Future".

University College London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. P. Bálint (University of Budapest): "The Reliability of Clearance Tests in the Evaluation of Renal Blood Flow".*

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. P. D. Bartlett (Harvard): "Peresters and Homolytic Fragmentation".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. J. S. Fulton: "The Future Pattern of University Education in the United Kingdom".

Wednesday, May 10—Thursday, May 11

Association for the Study of Medical Education (in the New Hall of the Students Hostel, London Hospital Medical College, Ashfield Street, Whitechapel, London, E.1)—Symposium on "Closed-Circuit Television in the Medical School".

Thursday, May 11

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. P. D. Bartlett (Harvard): "Autoxidation and Chain Termination".*

Society of Instrument Technology, Control Section (at Manson House, 26 Portland Place, London, W.1), at 6.15 p.m.—Annual General Meeting. 7 p.m.—Dr. W. Grey Walter: "Control Mechanism in the Human Nervous System".

Friday, May 12

British Interplanetary Society (in the Council Room of the Federation of British Industries, 21 Tothill Street, London, S.W.1), at 10 a.m.—Symposium on "Communications Satellites".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "The Place of Transistors in National Certificate Courses", opened by Mr. B. F. Gray and Mr. W. B. K. Ellis.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. T. Stanley Westoll, F.R.S.: "A Crucial Stage in Vertebrate Evolution: Fish to Land Animal".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer (preferably with special interests or qualifications in igneous and metamorphic petrology) in the Department of Geology—The Registrar, The University, Leeds 2 (May 12).

Postdoctoral Fellow in Organic Chemistry, to carry out researches into the behaviour of olefinic acids in strong acid media in collaboration with Dr. M. F. Ansell—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 12).

Lecturer in the Department of Metallurgy—The Registrar, The University, Liverpool (May 15).

Assistant Lecturer in Applied Mathematics—The Secretary, The Queen's University, Belfast (May 20).

Harry Bolus Chair of Botany in the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, May 20).

Lecturer in Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (May 20).

Lecturer (preferably with an interest in ecology and/or meteorology and climatology) in the Department of Geography - The Secretary, The University, Aberdeen (May 20).

Senior Lecturer in the Department of Physics—The Assistant Registrar (Science), The University, Edgbaston, Birmingham 15 (May 24).

Lecturer (preferably with research experience in plant-insect relations or a related field) in the Department of Horticulture, to teach biological aspects of horticultural crop protection - The Registrar (Room 22, O.R.B.), The University, Reading (May 31).

Lecturer (with a higher degree, preferably a Ph.D., and preferably experience in university teaching) in Chemistry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, May 31).

Research Fellow in Chemical Crystallography in the Department of Chemistry in the Faculty of Science to undertake investigations into the structures of complex natural products of biological importance and novel structural interest—The Registrar, University of Manchester, Manchester 13 (May 31).

Senior Lecturer in Inorganic Chemistry—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C.1 (May 31).

Senior Principal Scientific Officer (research worker with specialized knowledge and experience in animal research)—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (May 31).

Lecturer (preferably with experience in plant physiology or developmental anatomy) in Botany at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, June 2).

Lecturer/Senior Lecturer (interested and qualified in mineralogy and crystallography, and preferably with experience in X-ray techniques) in Geology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 9).

Lecturer in Education; and Lecturers (2) in Geography at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 15).

Chair of Physics (High Energy Nuclear Physics) in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Biochemist (non-medical) in the Department of Medicine, Makerere University College, East Africa, to participate in the current programme of research—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Chair of Physics in the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Chemist or Biochemist (honours graduate), to investigate fundamental aspects of the dehydration of meat—The Director, Low Temperature Research Station, A.R.C., Downing Street, Cambridge.

Head, Senior Scientific or Principal Scientific Officer (with a good honours degree in science or equivalent and previous research experience), of the Pig Section of the Applied Nutrition Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

Lecturer, and a Lecturer (Grade B) in the Department of Mathematics—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

Lecturer in Psychology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1.

Medical Laboratory Technician (qualified A.I.M.L.T., science degree or equivalent)—The Administrative Office, North London Blood Transfusion Centre, Deansbrook Road, Edgware, Middlesex.

Otto Beit Chair of Physiology; Senior Lecturers in the Department of Physiology; Lecturer in the Department of Pathology and Microbiology; a Senior Lecturer and Lecturer in the Department of Mathematics; and a Senior Lecturer and Lecturer in Physical Chemistry at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1.

Research Assistant (graduate) in the Mathematics Department, to work either in computing, mathematics or statistics—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

Research Fellow or Assistant (with a good honours degree in mathematics or engineering, and preferably experience in programming for a digital computer) IN THE DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS for work in the field of hypersonic gas dynamics—The Secretary and Registrar, The University, Southampton.

SENIOR LECTURER (graduate in botany, agriculture or horticulture, with teaching and research experience at university level, and preferably a knowledge of tropical crops) IN CROP HUSBANDRY at the University College of the West Indies (Imperial College of Tropical Agriculture, Trinidad)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

SENIOR LECTURER or LECTURER IN ORGANIC CHEMISTRY; a LECTURER IN INORGANIC CHEMISTRY; and an ASSISTANT LECTURER IN INORGANIC CHEMISTRY—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 9/G.

SENIOR LECTURER (qualified to teach microbiology to final degree and Diploma of Technology standard) IN MICROBIOLOGY IN THE DEPARTMENT OF BIOLOGICAL SCIENCES—The Registrar (Department F), Bradford Institute of Technology, Bradford 7.

CONQUEST OF SPACE

"ALL this world is heavy with the promise of greater things, and a day will come, one day in the unending succession of days, when beings, beings who are now latent in our thoughts and hidden in our loins, shall stand upon this earth as one stands upon a footstool, and shall laugh and reach out their hands amidst the stars." So H. G. Wells predicted in his discourse, "The Discovery of the Future", delivered at the Royal Institution on January 24, 1902 (*Nature*, **65**, 326; 1902).

Almost sixty years later the Academy of Sciences of the U.S.S.R. has given point to that prophecy. Man is entering a new régime of endeavour. Risen from intertidal slime, he now cleaves interstellar plasma. The astronautical venture has begun. For those who, from innate scepticism or lack of knowledge, have underrated this epic achievement as being no more important than rocketing instruments into space, some guidance is necessary. Apart from the sheer poetry of a human being undertaking such a Ulyssean journey, the scientific value is vast. Instruments, however ingenious, can only yield what they have been set to do. They are precluded from the realm of discovery. Man, with his natural universality and ability to reason, is at the very pinnacle of all discovery.

Unfortunately, the perspective received by the public is a trifle confusing. The reason is that astronautical programmes have given the impression of being somewhat of a random process—not wholly untrue this side of the Iron Curtain. However, Albert Ducrocq, a savant of note in astronautics and cybernetics, has managed in his book, *Victoire sur L'Espace**, to describe with much clarity the achievements and aims of space science. The book does not deal in detail with the development of space-vehicles, but provides an excellent review of performance and accomplishment. With Gallic limpidity of expression (not lost in the translation) he shows how the chief outcome of the astronautical revolution has been to make the scientific description of Nature more elegant.

Merely a few measurements made outside our planet have produced immense strides forward in certain branches of science. For example, as described in the famous report (March 28, 1959) by Academician A. N. Nesmeyanov, president of the Academy of Sciences of the U.S.S.R., the first *Sputniks* revealed that the density of the upper atmosphere is greater than was thought and composition is very different too, molecular forms of nitrogen and oxygen being essentially non-existent. Also, extreme turbulence with enormous variation in temperature and pressure appears to characterize this home of Vulcan. The very basis of meteorology has been transformed with such knowledge. Human intervention in directing the course of winds, rains and hurricanes may be envisaged. By analyses of the orbits, through application of Kepler's laws, the radius of the Earth has been estimated precisely. There appears to be a gravitational asymmetry suggesting a bulge in the southern part. Geophysical measurements have acquired a remarkable accuracy.

The existence of intense radiation at great height was indicated when the American *Explorer I* followed an eccentric orbit not planned by the technicians. It was an error on the plus side, since it led to identification, chiefly by Van Allen, of belts of radiation encircling our globe. It appears that the Earth is submerged within the Sun's atmosphere. These belts of plasma material having their origin in solar rays provide a link between solar events and their effects on Earth. For the first time outer space was used as a laboratory in an experiment known as 'Operation Argus'. An atom bomb was fired far out in space. Liberated electrons assembled almost instantaneously in the Earth's magnetic field to produce an artificial aurora. There is a danger in such experiments. Apart from causing the Earth's rotational speed to vary, repeated explosions could shatter the electrical equilibrium of the upper atmosphere, so playing havoc with our climates. This planet of ours seems to be rather delicately balanced.

What has distinguished the Soviet research in space is its direction toward the future. One investigation leads elegantly to another which, in turn, gives impetus to more extended work. While preparing for the future on a very large scale, Soviet scientists restrict the number of operations and make each as fruitful as possible. For example, it was puzzling that all three *Sputniks* should have been placed in orbits with low perigee, until one realizes that such satellites are at once atmospheric and geodetic, so yielding the greatest range of information. This powerful, ordered way of thinking is an interesting counterpoint to the impression one gets from the literature of Tolstoi, Dostoievsky and Bryúsov, for example, of the Russian mind, so passionately unrestrained. Therein probably lies their success.

Regrettably, one often finds naïve dismissal of Soviet scientific achievement as being another Machiavellian device for propelling the propaganda machine and making overtures to the 'uncommitted'. To be sure, the Russians do relate political prestige to their scientific endeavour. But this should not compel us to denigrate the sheer scientific attainment itself.

M. Ducrocq discusses the categories of problems encountered in space travel and how some of these have been surmounted. First, stabilization of various kinds was required to prevent space-vehicles from tumbling. This was done by creating an initial spin or by using ancillary fluid-ejection devices. He reviews problems related to re-entry. When a satellite returns into the atmosphere, it takes up a streamlined attitude according to aerodynamic influences.

---

* The Conquest of Space: Moon Probes and Artificial Satellites—Their Impact on Human Destiny. By Albert Ducrocq. Pp. 300+8 plates. (London: Putnam and Co., Ltd., 1961.) 30s. net.

But, on crossing the interface, it is likely to experience tremendous oscillations, comparable with the flapping of a flag. Uncontrolled kinetic heating can have dramatic consequences, as in the case of the early *V*2's, which exploded, in mid-air, despite their relatively low speed. A human occupant of a space-vehicle has to contend with a range of gravitational effects, and, for interplanetary voyages, there is the hazard of the radiation belts.

In travel to the Moon or planets the traditional notion of a journey no longer applies, since both the point of departure and the destination are moving. Such a voyage must be conceived in four-dimensional space. An advance without precedent in the 'conquest of precision' occurred when *Lunik II* was navigated to reach the Moon. The *Sputniks* had attained a precision of 1 per cent. For a shot to the Moon this represents an uncertainty of several tens of thousands of miles (with a régime close to unity). In January 1959, *Lunik I* took off at an initial speed controlled to within 0·1 per cent, already a ten-fold increase in precision since the previous year. It passed at 4,000 miles from the Moon. In September 1959 the staggering success of a precision of 0·01 per cent was gained when the second lunar probe landed on its target.

Thus for the first time spatial guidance was introduced. Using an ingenious iterative technique designed by Prof. Koteinikov and Prof. Chtchoukino deviation from an ideal ballistic path is measured *en route*, then small corrections are made. The vehicle is virtually steered to the Moon, which subtends an angle of only 0·5 degree as seen from the Earth. This amazing feat of gaining on the average one decimal place per annum attests to the directing influence of the Soviet astronautical programme, namely, to combine power with accuracy, each step paving the way for its successor.

It seems scientists may have attained yet higher orders of precision; at present a Soviet missile is in hot pursuit of the goddess of sweet intimacy. Sadly, perhaps, she will have to reveal her mysteries. M. Ducrocq discusses possible voyages to Mars as well and provides a very good summary of the elements of ballistic theory in an appendix.

It is indeed wondrous to witness how mankind, though thwarted and frustrated, often by its very nature, can, like Ulysses, ever feel that force

> "To follow knowledge like a sinking star
> Beyond the utmost bound of human thought."

A FURTHER TRIUMPH FOR SCIENCE

As is now universally known, American scientists and technologists achieved a great victory when, on May 6, they were responsible for the projection of a rocket carrying a man (Commander Alan Shepard) into sub-orbital space, the capsule being recovered intact with Commander Shepard alive and well. This is a record of a controlled flight 115 miles high and 302 miles down-range.

The congratulations of all must be extended to the American scientists and technologists who made this feat possible; and we express great admiration to Commander Shepard for his valour and devotion to duty.

This American achievement follows closely on that of the Soviet scientists, who, on April 12, succeeded in placing a controlled space-vehicle in orbit containing a man (Major Gagarin) and also recovered him alive and well (see *Nature* of April 22, p. 291).

In announcing their achievement, the Soviet political authorities stated: "We gladly place them [the scientific results] at the service of all peoples in the name of progress, happiness and the well-being of all human beings on Earth". Similarly, from the White House, the President of the United States, commenting on this most recent American space victory, stated: "Important scientific material has been obtained during this flight and this will be made available to the world's scientific community".

Here are two great scientific feats achieved by two Powers more or less diagonally opposed in political creed. While the world's scientists must share satisfaction in the almost fantastic progress thus revealed, all and sundry should view with grave concern and no little apprehension the politics behind it.

As pointed out in our previous comment (*Nature* of April 22), it still seems that only lip service is being paid to freedom for scientific research and, above all, freedom to publish and discuss scientific results—to the ultimate benefit of man. We are glad to read the Soviet and American promises to release these, their latest, results, but shall feel happier when such promises are implemented, for until then scientific progress is shackled and world peace possibly threatened. To-day, far too much science is censored, and this is bound to cause international bad faith and suspicion.

Commenting on the great American achievement, a spokesman in the Soviet Embassy in London said: "This stage of development was reached several years ago in the Soviet Union". Most men of science, and indeed others, will be prepared to accept this as a fact; but it is significant that the Russians, so far as we know, made no announcement at the time or published any scientific results afterwards. On the other hand, the Americans have not only published immediately the actual fact of their success, but also did everything they could (through radio, television, etc.) to allow the world to follow the last stages of their gigantic experiment (for there must have been many stages before the actual launching of the rocket)—even at the risk of enacting a failure.

It is relevant here to reveal that for some years *Nature* has tried to persuade the Soviet authorities (through the media of some of their scientists) to allow their magnificent scientific results (not confined to space research) to be published for all to read; and very recently approaches have been made direct to political authorities in Moscow and to the Soviet Ambassador in London; but, alas, so far with negative results.

To most non-scientists, the successful pioneers in these recent space researches are Gagarin and Shepard. Yet, with all due respect to these brave men, they themselves were actually part of certain scientific equipment. The fundamental work was done by, and therefore praise is also due to, the scientists who made possible the heroic feats of these two men. In fact, these journeys into space are the results of the work of many people over many years, culminating in team work among scientists and non-scientists. Alas, however, thanks mainly to the fundamental defects in the world's means of mass information and education, the scientists are relegated by the layman to an almost intangible, certainly generally incomprehensible, position, and have to suffer such vulgar epithets as 'back-room boys' or 'boffins'.

Such men as Gagarin and Shepard have had, and will continue to receive, public acclaim and fêting which is their due, though much of this may well verge on hysteria stimulated by political propaganda and national patriotism. Meanwhile, the scientist goes quietly on with his work.

One sometimes wonders if such national and international acclaim would be accorded to a man who discovered an over-all cure for cancer or who made two blades of grass grow where only one or none grew before. Certainly no such world-wide publicity and praise were meted out to those scientists who were responsible for the discovery and development of penicillin in the late 'thirties and onwards: yet to-day, as a result of this work, millions of lives are being saved, much suffering alleviated and a great industry of antibiotics established in many parts of the world.

We would be the last to wish to denigrate the contributions Major Gagarin and Commander Shepard have personally made to the advancement of space science; but these two achievements, and especially the way in which they are being presented to the world, help to emphasize what *Nature* has been stressing continuously for some years, that is, the great danger inherent in allowing science to become the tool of political and diplomatic intrigue; for from scientific endeavour coupled with diplomatic intrigue it is only a short step to scientific success possibly coupled with political threat. Neither is it wise that scientific achievements be used for the enhancement of political prestige.

Until we have a world where all or most of its peoples are sufficiently educated or informed about things scientific, we shall travel further and further into that dread arena where politicians are playing ball with bombs—a dangerous game having no referee, not even the United Nations, who are certainly not yet wholly united in scientific endeavour.

MORE RECENT ADVANCES IN BIOCHEMISTRY

Recent Advances in Biochemistry

By Prof. T. W. Goodwin. Fourth edition. Pp. vi+301. (London: J. and A. Churchill, Ltd., 1960.) 50*s*. net.

It will probably come as a surprise to most readers of this book to find it described as the fourth edition of *Recent Advances in Biochemistry*. The third edition of a book with this title appeared in 1931. It was written by Prof. J. Pryde and was a landmark in biochemical literature. The present book is by a different author and the whole subject of biochemistry has, of course, become transformed in the intervening thirty years. Two consecutive editions of a book could scarcely be more different; yet the present one is likely to take a similarly outstanding place in the literature. The aim of the book is to bridge the gap between the general text-book and the specialized review article, and to introduce senior undergraduate students and research workers to some of the present-day frontiers of biochemical discovery. In a book of eight chapters, it has been possible to deal only with selected topics, and emphasis has been placed on mechanisms of biosynthesis, with a leaning towards the chemical rather than the physiological aspects of biochemistry.

Chapter 1 deals with electron transport and oxidative phosphorylation. Here, as elsewhere in the book, the author describes not only the known facts but also their experimental basis. Chapter 2 is concerned with carbon dioxide fixation in higher plants and micro-organisms and in animal tissues. It includes a discussion on the Krebs urea-cycle. The chemistry and biosynthesis of phospholipids is covered in Chapter 3, and the biosynthesis of aromatic and heterocyclic ring compounds in the next two chapters. These are followed by a discussion of the nucleic acids: "The compounds which perhaps more than any dazzle biochemists and biologists alike with the glittering prospect of an explanation of the ultimate mysteries of living matter". The subject is treated from the synthetic rather than the functional aspect, but there is an interesting discussion of recent work on the infection of *E. coli* by different strains of bacteriophage. Chapter 7 deals with biosynthesis of terpenes and related compounds, and contains a detailed description of the steps leading to the biosynthesis of cholesterol. Carotinoids are included in this chapter, and here the author is on his home ground for he has contributed much to our knowledge of the biochemistry of these compounds. The book ends with a short but most valuable chapter on the regulation of cell metabolism, a subject of great interest and importance, but one which has scarcely reached the text-books yet.

Throughout the book there are numerous references to the more significant original articles and there is a useful index. The author makes very free use of abbreviations for the names of compounds: indeed, some pages look as if they might have been written in code. Some of these abbreviations are not in common use; others, such as DPN, may soon become obsolete (see *Nature*, 188, 464; 1960). It would save readers a lot of unnecessary searching if, in future editions, an alphabetical key to abbreviations were supplied at the beginning or end of the book. The standard of production is good, and the numerous diagrams of formulæ and reaction scheme-are clearly set out. This book will be greatly valued by research workers and teachers and, perhaps above all, by undergraduates in their final year of honours biochemistry. Organic chemists will find much to interest them too. It is not easy reading because of the complexity of the subjects discussed, but the chosen ground could scarcely have been covered better in a book of this size. It is much to be hoped that Prof. Goodwin will have the time and patience to bring out further up-to-date editions of this book from time to time. D. C. HARRISON

ANIMAL BEHAVIOUR

Current Problems in Animal Behaviour

Edited by W. H. Thorpe and Prof. O. L. Zangwill. Pp. xiv+424+2 plates. (Cambridge: At the University Press, 1961.) 45*s*. net.

THE phenomena of animal behaviour are being studied by a rapidly increasing number of scientists. Few other biological phenomena have attracted such a variety of workers and have led to so many differently oriented disciplines. After a period in which these various disciplines ignored each other, a tendency grew towards establishing contact; this at first expressed itself in mutual criticism, but it is gradually developing into real co-operation. Because the subject is so complicated, because it also offers more obstacles to consistent scientific inquiry than most other life processes, and further because each class of workers has developed its own concepts, terminology and theories during periods of isolation, the growth of co-operation is a difficult and painful process. In spite of this, and notwithstanding a growing tendency towards specialization, an increasing number of workers is seriously attempting to build at least a common foundation for a unified, broad and systematic attack on problems of animal behaviour. These attempts naturally require much discussion, and in many research centres there have been formed interdisciplinary discussion groups in which problems, methods, concepts and concrete research plans are critically considered.

The present book gives us an insight into the kind of activities of such seminars. Each member of Dr. Thorpe's and Prof. Zangwill's alert and able group "was asked to write an essay on an aspect of his own work or discipline which appeared to him interesting and vital for the study of behaviour as a whole"; these essays were then critically discussed and rewritten.

The result is a series of extremely worth-while chapters, loosely bundled into four major parts. The editors jointly wrote a general introduction, and each part is again introduced by one of them.

Part 1 ("Neural Mechanisms and Behaviour") contains a chapter by D. M. Vowles in which differences between the nervous systems of insects and vertebrates are traced, and constructive chapters by L. Weiskrantz and O. L. Zangwill. Part 2, not quite appropriately called "Experimental Studies of Animal Behaviour", contains chapters on ritualization (A. D. Blest), on flock organization in birds (J. H. Crook) and on filtering of external stimuli (P. Marler); Part 3, on "Problems common to the Psychology of Animals and Men", has 5 chapters (R. A. Hinde, W. H. Thorpe—whose contributions overlap a little—M. A. Vince, D. E. Broadbent and A. J. Watson) and the last part deals with "Theoretical Approaches" (R. L. Gregory, H. B. Barlow and V. Cane).

While such a book can of course not be expected to be an exhaustive review, it is amazing how many aspects of the field are given critical attention, and how many chapters present really new points of view. Not unexpectedly, there is a great deal of trial-and-error thinking in print, and if the trend of some contributions is a little over-destructive, this reflects the soul-searching state our science is in. Nor should it be forgotten that there has been a considerable delay in publishing.

The title, and particularly the sub-title, perhaps suggest a more exhaustive covering and more unity of approach than are really presented. When the editors state that "the psychologist is . . . interested in . . . the explanation of behaviour in general" (p. x) they are, I feel, underrating the facts that the narrow descriptive basis of psychology makes it at times difficult to distinguish the general from the special, and that the undoubtedly general problems of survival value and evolution are still neglected in psychology. Furthermore, when they say that "biology is *still* very largely dominated by the concept of evolution" (p. xii, italics mine), do they mean that this is a passing stage, which biology will outgrow, and which psychology has already outgrown? N. TINBERGEN

AXIOMATICS AND FOUNDATIONS

The Axiomatic Method, with special reference to Geometry and Physics

Proceedings of an International Symposium held at the University of California, Berkeley, December 26, 1957–January 4, 1958. Edited by Prof. Leon Henkin, Prof. Patrick Suppes and Prof. Alfred Tarski. (Studies in Logic and the Foundations of Mathematics.) Pp. xi+488. (Amsterdam: North-Holland Publishing Company, 1959.) 90*s*.

The Foundations of Mathematics

A Study in the Philosophy of Science. By Evert W. Beth. (Studies in Logic and the Foundations of Mathematics.) Pp. xxvi+741. (Amsterdam: North-Holland Publishing Company, 1959.) 100*s*.

THESE two books, different in emphasis but alike in purpose, present an inspiring picture of modern thought concerning the basis of mathematics. The drilling into the sub-structure of the subject goes on with relentless vigour. The whole field is becoming so vast that expertize within expertize is beginning to appear, which means that the student needs instruction of course, but guidance as well, through the mass of highly specialized literature. All this is provided in good measure.

Axiomatic Method is the outcome of a conference held in 1958. Its general theme, as the title suggests, is the formal structure of mathematics. The deliberations are divided into three parts: (1) foundations of geometry; (2) foundations of physics; (3) general problems; and applications of the axiomatic method. In the first of these the order is that of subject, in the second of historical development, and in the third (broadly) from the more specific to the more general. The reader will appreciate this plan, but the purpose behind the arrangement is worth noting. Geometry has been the home ground of axiomatics for more than two thousand years, and in that field the method originated. It would be quite unnatural if any sequence other than by subject were adopted. But physics has not developed like that, and so the chronological treatment is the better. In fact, to-day physical research is often curiously informal (in the technical sense), and its theoretical side is frequently kept lively and progressive by the need to resolve some inconsistency or to remove some apparent paradox thrown up by experiment. Newton's *Principia* has indeed more than a touch of Euclidian methodology. But of that, more anon.

There are at least two classic examples in which the axiomatic principle worked well in physics under the hand of a great master. The first was Archimedes, and the second Carathéodory, who in 1908–9 set up a system of thermodynamics on the basis of two axioms. Neither of these receives comment. The omission is by no means serious, since much of the work discussed is—very properly—modern. But it would have been interesting to have had the editors' reactions to the contributions made by such outstanding minds separated by such a long period of time.

Concerning the particular 'atmosphere' of the Newtonian period, and the seeming lack of postulates or any other kind of 'common notions', it looks very much as if the influence of Francis Bacon was too dominant, and that stress was laid very firmly on the power of science (in general) as an instrument of progress. If this should be a correct interpretation of events, it would follow that induction rather than deduction was *de rigueur* in the prevailing intellectual climate.

Turning to applications of the axiomatic method (Part 3), Prof. R. L. Wilder, of the University of Michigan, has a most intriguing paper on the innovations which he brought about in teaching his postgraduate students to use such a powerful tool for themselves in the establishment of proofs, sufficiently refined and complete to satisfy twentieth-century standards of consistency and adequacy. In this way (and occasionally even at undergraduate-level) he claims to have discovered creative talent otherwise dormant or perhaps frustrated.

The Foundations of Mathematics has a somewhat different aim. It is essentially a treatise, covering almost all aspects of foundation theory, but axiomatic in spirit, though this aspect is confined to Parts 2 and 3. Part 1 provides an exceptionally lucid study of the historical background of foundations, with particular reference to Aristotle's Theory of Science, and the rise of symbolic logic—which must, almost of necessity, include a brief outline of formalized axiomatics. Further parts deal with such topics as non-elementary mathematics, the existence of mathematical entities, paradoxes, set-theory and topology, recessive functions, sets and predicates. In conclusion come some comprehensive remarks on metamathematics and philosophy. Prof. E. W. Beth has some shrewd observations to make on the countless—often amateurish—efforts to resolve the more important paradoxes. Having expounded the orthodox views on such matters, he implies, very gently, that they have too often suffered from the 'fools and angels' type of attention. It is all too easy to under-estimate the methodological significance of the paradoxes, as well as to fall short of present-day standards of rigour in any approach to clarify their more intractable features.

The author's method is, in principle, analytic. He is thus enabled to deal with questions as they arise, rather than to ask his readers to accept assertions which may be far from obvious. Again, he recognizes that even logic may be a matter of degree: beginning at an "average level", he is able to scale the heights as the work proceeds. From the students' point of view, the realization of this dynamic process is important.

Reference to sections would be facilitated if the section numbers could be printed at the top of each page. As it is, much searching is involved to find such necessary information, especially when an equation or formula is first encountered, and then mentioned again many pages ahead.

F. I. G. Rawlins

GROUPS, PURE AND APPLIED

The Theory of Groups

By A. G. Kurosh. Translated from the Russian and edited by K. A. Hirsch. Second English edition. Vol. 1: Pp. 272. Vol. 2: Pp. 308. (New York: Chelsea Publishing Company, 1960.) 4.95 dollars each volume.

Abelian Groups

By L. Fuchs. Pp. 367. (London and New York: Pergamon Press, 1960.) 63*s*. net.

Seminar on Transformation Groups

By Armand Borel. With contributions by G. Bredon, E. E. Floyd, D. Montgomery and R. Palais. (Annals of Mathematics Studies, No. 46.) Pp. viii+245. (Princeton, N.J.: Princeton University Press; London: Oxford University Press 1960.) 36*s*. net.

THE two volumes by A. G. Kurosh, in their American translation by K. A. Hirsch, as well as the book by L. Fuchs, are photographic reprints of the first editions that appeared in 1955 1956 and 1958 respectively. A few misprints have been corrected in this second American edition of Kurosh's book; the Pergamon Press has appended a short list of errata to Fuchs's book which was first published by the Hungarian Academy of Sciences, but the present reprint is not even described as a second edition. The short space of time that has elapsed since their first appearance is a measure of the success and the importance of these books. But a glance at their history will explain why this time is too long for them to re-appear unchanged: it would have been more in keeping with the spirit of these books if some of the recent advances that they themselves have done so much to stimulate had been included.

The theory of groups, now one of the most important branches of abstract algebra, has seen a spectacular burst of activity during the past few decades. Kurosh's book is remarkable for the way in which its various editions are in turn result and cause of this development. Kurosh first wrote *The Theory of Groups* in 1940. It was then the first book on just groups, rather than finite groups, and the stress was on infinite groups. The War delayed publication until 1944, and the book became available to a wider public only in 1953 when the Akademie-Verlag, Berlin, published a German translation. By that time the stimulus provided by the Russian original had led to numerous new discoveries, some of which were added to the German translation in an appendix by B. H. Neumann. In the meanwhile, Kurosh himself had completely recast and revised his book in the light of the rapid advances, especially in the theory of infinite nilpotent groups, made by the powerful school of Russian group theorists. Thus, in the same year 1953, the second Russian edition appeared, virtually a new book compared with the first edition. It is from this second edition that Hirsch's translation was made. Once again Hirsch supplemented the translation by notes reporting on more recent developments. He also brought the bibliography up to date—that is, up to 1956—so that it now includes more than 800 titles.

The theory of abelian groups, though part of general group theory, has its own methods and its own history of growth. A first account of the theory of infinite abelian groups appeared in 1954, in a well-known monograph by I. Kaplansky. Here again further progress was rapid, and Fuchs's book in 1958 came none too early. Naturally, so far as the basic structure theory is concerned the books overlap. Beyond that much of the characteristic flavour of Fuchs's book is due to the fact that it, too, comes from the pen of one of a lively school of research workers in the subject, this time the Hungarian school of group theorists. Indeed, a glance at the extensive bibliography and at the numerous examples at the end of each chapter, many of them provided to give additional information on recent results in concise form, reveals the vigour of the (then) current research.

Both books start from the beginnings of the subject, assuming no more than a certain maturity of mathematical reasoning and familiarity with some basic mathematical tools. Both lead to the frontiers of knowledge in their time, giving not only the latest results but also pointing again and again to the unsolved problems and open questions. Thus both books are suitable for, in fact strongly recommended to, the bright undergraduate and the young research student; at the same time their depth and scope make them indispensable for the expert. Some of the most striking discoveries made since their appearance owe much to the influence of these books; many of the problems they state are, in fact, now solved. Let us hope that a further edition may soon be possible.

By contrast, the book by Armand Borel and his collaborators deals with a highly specialized application of group theory and homology theory. It embodies the results of a seminar held by Borel at the Institute of Advanced Studies at Princeton, N.J.; several chapters are written by members of the seminar presenting their own contribution to its work. The topic is the application of cohomological methods to the study of the action of compact transformation groups on topological spaces; the tools, ranging far and wide over recent work in algebraic topology, are mainly taken for granted, though a general reference to the sources is provided. At this different level of specialization the presentation is again clear and well organized, but naturally concise. Each chapter carries its own short bibliography, not aiming at completeness but containing only the most relevant papers. This book is clearly for the expert only.

HANNA NEUMANN

POWDER METALLURGY

Fundamental Principles of Powder Metallurgy

By Dr. W. D. Jones. Pp. xii+1032. (London: Edward Arnold (Publishers), Ltd., 1960.) 147*s*. net.

POWDER metallurgy is becoming an increasingly important metallurgical process, and, though a number of comprehensive books on the subject have been published in the United States, it is very useful to have this long and detailed book published in Great Britain and written by an author with such wide experience in powder metallurgy. Dr. Jones is the author of the well-known book *Principles of Powder Metallurgy* published in 1937.

The new book starts with a long chapter of 239 pages on the preparation of powders and then has three chapters, totalling 350 pages, on "Pressing", "Shaping without Pressing" and "Sintering". These are followed by another very long chapter on "Attainment of Specific Qualities", which deals mainly with the properties required in products made by powder metallurgy, but which also contains a section on factory management. The book ends with two short chapters on "Continuous Powder Metallurgy" and "Methods of Control"; the former covers the three main methods of continuous compacting of powders; the latter is very short and merely lists the various methods of testing powders and compacts and states where details of the actual tests can be found.

The author states in his introduction that he intends to cover principles rather than practice and so detailed descriptions of plant and processes are not included. Apart from this omission the book is very comprehensive; very little, if anything, appears to have been left out. The book is written in a clear and simple manner with good and relevant illustrations.

The book will be essential for all metallurgical libraries, since some at least of the matters described will be of importance or interest to all metallurgists. It will also be useful to others who are not metallurgists, so important are powders in modern technology.

It is possible that with the development of processes such as the Sherritt–Gordon process for the reduction of metals from their ores, the final products of which are powders, powder metallurgical products will no longer be used only for small or specialized components but will also be used for large-scale processes.

As has been said, the book is long, more than a thousand pages, and at seven guineas is expensive. The length and cost could have been reduced by omitting parts which do not fall strictly within the province of powder metallurgy or which can be found in standard text-books. Examples are the descriptions of the properties of metal whiskers and of general magnetic properties. The section on "Powder Metallurgy as a Competitive Process" does not, as might be expected from its title, show when it is economical to use powder metallurgy rather than other processes, but describes the organization of a factory producing powder metallurgy products. The section is interesting, but it is doubtful whether the organization of such a factory differs in its essentials from any other factory producing small parts.

J. H. RENDALL

The Brittle Fracture of Steel

By Dr. W. D. Biggs. Pp. xxvi+420. (London: Macdonald and Evans, Ltd., 1960.) 70*s.* net.

IN this book the author gives a very thorough account of all the factors related to the brittle fracture of structural steel. Thus he details a vast amount of accumulated knowledge on deformation and fracture, and discusses service and design aspects as well as methods of testing and the effect of metallurgical variables on behaviour. In addition, he deals with the relation between welding and brittle fracture, and the significance of residual stresses. Although cast irons are briefly mentioned, the coverage on steel does not extend to alloy steels as such.

The text is authoritative and comprehensive. However, as a result of the wide treatment the book does not readily yield a concise overall picture. The diffuseness in increased by the fact that in places the style is rather involved. This tendency is most noticeable when the author is generalizing rather than when he is giving specific information. There is indeed a useful summary chapter of fourteen pages, but it would have been better if this had been subtitled and set down in a crisper style.

In conclusion, it must be emphasized that this is a sound and informed book providing a thorough development of the subject-matter, and in this respect it deserves recognition as a valuable reference work. Regarding the style, the remarks here of course merely indicate my own reaction. Nevertheless, it does seem that the book would have been much easier to assimilate had the author cut through the subject in a more incisive manner.

A. R. BAILEY

Proceedings of the Fourth International Conference on Ionization Phenomena in Gases

Uppsala, 17–21 August, 1959. Edited by N. Robert Nilsson. (Series in Physics.) Vol. 1: Pp. xii+552. Vol. 2: Pp. viii+553–1210. (Amsterdam: North-Holland Publishing Company, 1960.) £12 6*s.* 0*d.* the two volumes.

THESE two volumes contain the majority of the 250 papers which were read at the conference by scientists actively engaged in the field of ionization physics in twenty-one countries throughout the world. The papers, by far the greater number of which are in English, cover a very wide range of topics, but they have been conveniently grouped so that Volume 1 contains those concerned with fundamental ionization processes and various types of gas discharges, and Volume 2 those dealing with various aspects of plasma physics. (More detailed information about the topics discussed under these general headings was given in a recent report on the conference[1].) It would have been helpful to the reader if the review papers, given to the plenary sessions of the conference, could have been distinguished in some way from the more detailed papers read to the four parallel sessions into which the conference was divided for much of the time. It is also a pity that the often lively and informative discussion of the papers had to be omitted for reasons of space. These, however, are minor criticisms, and both the editor and publishers are to be congratulated on providing such a very well-produced record of this important and extremely well-organized conference. All those with an interest in this field of work will wish to have ready access to these volumes in their departmental library, even if the inevitably high price precludes them from owning their own personal copies.

J. DUTTON

Determination of the Mechanical and Technological Properties of Metals

By B. M. Gliner. Translated from the Russian. 2nd edition. Translation Editor: E. Bishop. Pp. ix+160. (London and New York: Pergamon Press, 1960.) 50*s.* net.

THIS book gives a useful résumé of Russian mechanical testing methods. On the assumption that it contains a reasonably modern exposition (no date is given in the translated preface) of the varied techniques, it reveals no startling divergences from Western practice, although there are two unusual features that are mentioned.

One of these features is the use of ring and splitring test pieces, for testing under short-time transverse tension, at room temperature, and transverse creep tension, at elevated temperature, respectively. It is not made clear why, or on what scale, such test pieces are used, or what information, other than an empirical guide to design, is gained from the tests.

The other unusual feature is the use of a triangular pyramid indentor for micro-hardness testing. It is difficult to see what particular advantage is gained by this form of indentor, other than to average out directionality effects in the material.

A statement is made (on page 14) that load measurement is most accurately achieved by means of a pendulum lever mechanism. This will certainly be questioned by Western manufacturers unless it is taken as a reflexion on Russian machine construction methods.

There are one or two minor errors to be found; for example, Fig. 61(*b*) is incorrect.

If the translation were less literal then the book would be easier to read. For example, on p. 16, "jockey" would read better than "trolley", on p. 17, "drum" would be better than "box", and "I-section" would be better than "Type 1", and on p. 93, "disk" is preferable to "shaft".

JAMES G. TWEEDDALE

Practical Heredity with Drosophila

By Dr. Gordon Haskell. Pp. xii+124. (Edinburgh and London: Oliver and Boyd, Ltd., 1961.) 10*s.* 6*d.* net.

IT is surprising that this useful little book has not been written before. Elementary practical genetics is studied in many schools and colleges, and, because of inexperience of the manipulators, many breeding errors occur which could have been avoided. Haskell's book provides valuable hints on the means of obtaining and rearing pure stocks of *Drosophila*, the apparatus required to do this and the right ways to use it, the selection of suitable mutants to demonstrate genetic principles, statistical tests for evaluation, the cytology of *Drosophila* and an introduction to biometrical investigation. Many workers using *Drosophila* who have tried in vain to mate already pregnant females will be glad of all the practical help which Haskell has compressed into quite a short space.

T. H. HAWKINS

SEASONAL VARIATION AND AGE OF RADIOACTIVE FALL-OUT

By R. P. PARKER and J. O. CROOKALL

Physics Department, Institute of Cancer Research, Royal Cancer Hospital,
Fulham Road, London, S.W.3

A NUMBER of observers in the temperate zones of the northern hemisphere have reported a seasonal variation in the concentration of long-range fall-out material[1-3]. Thus both dust samples collected from surface air and rain-water samples have shown higher activities in the late spring than in the late autumn. It has been suggested by Martell[4] that the spring maxima are due to the descent of fall-out material injected into the atmosphere by tests in the previous autumn, while Stewart *et al.*[1] have suggested an explanation on meteorological grounds using the Brewer–Dobson model of atmospheric circulation[5,6]. On the latter thesis the cold air which forms above the Pole during the late winter sinks in the spring, thus bringing down stratospheric air and associated fission debris. More recently Feely and Spar[7] have postulated that the movement of fission debris from the stratosphere into the troposphere primarily occurs by a process of turbulent mixing in the region of the troposphere gap.

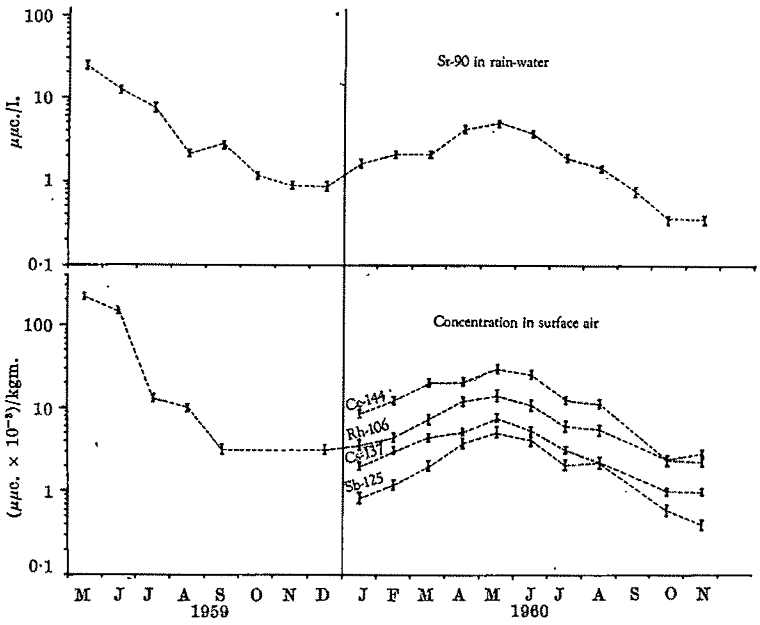

Fig. 1

In the past it has been difficult to assess the relative importance of these views owing to the periodic injection of fresh nuclear debris into the atmosphere. For example, Anderson *et al.*[2] have shown that while the fall-out pattern for 1959 was consistent with Martell's suggestion, it could not be taken to exclude a seasonal variation of the type suggested by Stewart. The spring of 1960 presented the first opportunity of studying this variation virtually free from the effect of recent tests. (The tropospheric fall-out from the 1960 French tests had only a transitory effect in Britain[8], and the yields were too small to produce a significant contribution to the total activity in the stratospheric reservoir.) We have already reported measurements for the early part of 1960[2] which indicate the beginning of a rise in the concentration of fall-out material, and more recently Peirson *et al.* have published measurements of the cæsium-137 content of surface air up to the middle of 1960, which show a maximum in the spring[3]. We present here measurements of the principal γ-emitting fission products in surface air in 1960, together with values for the strontium-90 content of rain-water during this period. As before[2,9], samples of dust collected from surface air by means of an electrostatic precipitator at our laboratory at Sutton, Surrey, have been analysed by means of γ-spectrometry.

The principal γ-emitting fission products present in our 1960 samples are cerium-144, cæsium-137, rhodium-106 and antimony-125, as expected for a period 12–24 months after fission[10]. In addition to the photo-peaks in the γ-spectrum which may be ascribed to the above nuclides, the identity of which has been corroborated by decay measurements on a number of samples, a peak occurs at an energy of 0·475 MeV. We have previously shown[8], on the basis of chemical and physical evidence, that this is in part due to 53-day beryllium-7, a product of the interaction of cosmic rays with atmospheric nitrogen and oxygen nuclei. The situation is now further com-

plicated by the presence of 210-day rhodium-102, recently reported to have been produced as a tracer in certain of the American 'Hardtack' explosions of April-August 1958[11,12]. Recently this nuclide has been stated to emit principal γ-rays of energy 0·475 MeV. (63 per cent) and 1·09 MeV. (6 per cent)[13]; but earlier decay schemes suggested a higher intensity for the 1·09-MeV. line. The rhodium-102 photo-peak at 0·475 MeV. cannot be resolved in our apparatus from the 0·478-MeV. line of beryllium-7, and, if we accept the new data, the intensity of the 1·09-MeV. line is too weak for it to be used in the identification of the small amounts of rhodium-102 which may be present in our samples. We are therefore carrying out further work to determine the relative amounts of beryllium-7 and rhodium-102.

Our measurements on the specific concentrations of rhodium-106, antimony-125, cæsium-137 and cerium-144, corrected for decay to the time of the collection, are given in Table 1. After averaging over calendar months, the results are plotted in Fig. 1, together with the strontium-90 concentrations in rain-water samples (Table 2). These measurements form a continuation of work previously reported[2].

The common feature of all these results is the pronounced rise to a maximum in May, with a fall during the summer months to low autumn and winter values. From June until October the values for the strontium-90 concentrations in rain are a close fit to an exponential curve of half-period 40 days, which is remarkably similar to our results for 1959[2]. The ratio between maximum and minimum in 1960 is approximately 5 : 1. This is in agreement with results for strontium-90 in rain during 1955–58[14], and with the finding that the poleward transfer of tungsten-185, liberated as a tracer in certain of the American tests near the equator, is seasonal[7,15]. It would therefore appear that our results may be explained in meteorological terms by the Brewer-Dobson or Feely-Spar models, since the Martell thesis is not applicable in 1960.

Information on the age of the debris collected may be obtained from the relative proportions of the various nuclide activities present in our samples. The yield of both cerium-144 and cæsium-137 is relatively independent of the type of fission process (Table 3)[10], and therefore the ratios of the specific activities of these nuclides provide a suitable method of determining age at the present time. The concentrations of nuclides of shorter half-life, such as strontium-89 and zirconium-95, are now too low for accurate measurement[8].

Table 3. Fission Yield (per cent) for Different Types of Fission (ref. 10)

Mass-chain	Half-life	U-235, n_f	Pu-239, n_f	U-238, n_f	U-238, n_{14}	U-235, n_{14}
106	370 days	0·47	6·17	2·61	3·11	1·40
125	2·4 years	0·12	0·26	0·05	1·00	1·36
137	30 years	6·18	6·14	6·45	5·71	5·10
144	285 days	4·76	3·66	4·42	3·32	3·30

n_f, fission spectrum neutrons; n_{14}, 14-MeV. neutrons.

Our experimental cerium-144/cæsium-137 ratios are listed in Table 1, and it is interesting to note that during the early part of 1960 they are in good agreement with values quoted for rain-water at Milford Haven[16]. Using the theoretical yield values (Table 3) the average age for each sample has been calculated, and the results are presented in Fig. 2. The error in any one value is estimated to be ± 20 per cent. If we take the mean of these estimated dates of origin, a time April–May 1958 is obtained.

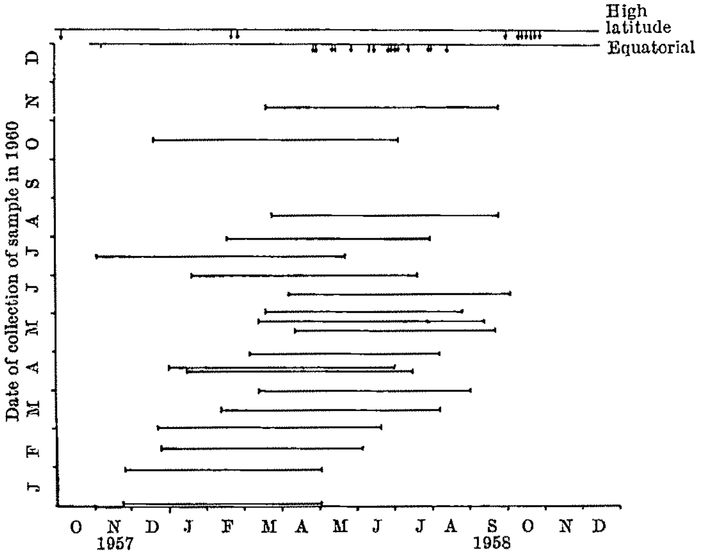

Fig. 2

This is compatible with available information on the dates of megaton explosions[17]; these are indicated by arrows at the top of Fig. 2. The above calculation is based on the fission yield for 14-MeV. neutrons, and in the unlikely event of all the yield being due to the fission of uranium-235 by fission neutrons the mean date of origin would be approximately four months earlier. Thus the majority of fall-out material collected at our site during 1960 probably originates from the American and British equatorial tests of 1958.

The antimony-125/cæsium-137 and rhodium-106/cæsium-137 ratios had experimental values in mid-1960 of approximately 0·6 and 1·9 respectively. These are commensurate with an age of 3–4 years if 14-MeV. fission yields are used. However, the yield of both antimony-125 and rhodium-106 is very sensitive to the type of fission process, as shown by Table 3. Thus the discrepancy may be explained if, in addition to the 14-MeV. fission of uranium-238, other fission processes are involved.

We wish to acknowledge the guidance and encouragement of Prof. W. V. Mayneord and Dr. W.

Anderson during this work. We also wish to thank Mr. R. W. Kent and Mr. D. Smith for their help in connexion with the electrostatic precipitator, and Mrs. A. Perry for assistance in the chemical analyses.

AN UNSTABLE INTERMEDIATE CARRYING INFORMATION FROM GENES TO RIBOSOMES FOR PROTEIN SYNTHESIS

By DR. S. BRENNER

Medical Research Council Unit for Molecular Biology, Cavendish Laboratory,
University of Cambridge

DR. F. JACOB

Institut Pasteur, Paris

AND

DR. M. MESELSON

Gates and Crellin Laboratories of Chemistry, California Institute of Technology,
Pasadena, California

A LARGE amount of evidence suggests that genetic information for protein structure is encoded in deoxyribonucleic acid (DNA) while the actual assembling of amino-acids into proteins occurs in cytoplasmic ribonucleoprotein particles called ribosomes. The fact that proteins are not synthesized directly on genes demands the existence of an intermediate information carrier. This intermediate template is generally assumed to be a stable ribonucleic acid (RNA) and more specifically the RNA of the ribosomes. According to the present view, each gene controls the synthesis of one kind of specialized ribosome, which in turn directs the synthesis of the corresponding protein—a scheme which could be epitomized as the one gene–one ribosome–one protein hypothesis. In the past few years, however, this model has encountered some difficulties: (1) The remarkable homogeneity in size[1] and nucleotide composition[2] of the ribosomal RNA reflects neither the range of size of polypeptide chains nor the variation in the nucleotide composition observed in the DNA of different bacterial species[2,3]. (2) The capacity of bacteria to synthesize a given protein does not seem to survive beyond the integrity of the corresponding gene[4]. (3) Regulation of protein synthesis in bacteria seems to operate at the level of the synthesis of the information intermediate by the gene rather than at the level of the synthesis of the protein[5].

These results are scarcely compatible with the existence of stable RNA intermediates acting as templates for protein synthesis. The paradox, however, can be resolved by the hypothesis, put forward by Jacob and Monod[5], that the ribosomal RNA is not the intermediate carrier of information from gene to protein, but rather that ribosomes are non-specialized structures which receive genetic information from the gene in the form of an unstable intermediate or 'messenger'. We present here the results of experiments on phage-infected bacteria which give direct support to this hypothesis.

When growing bacteria are infected with a virulent bacteriophage such as *T*2, synthesis of DNA stops immediately, to resume 7 min. later[6], while protein synthesis continues at a constant rate[7]. After infection many bacterial enzymes are no longer produced[8]; in all likelihood, the new protein is genetically determined by the phage. A large number of new enzymatic activities appears in the infected cell during the first few minutes following infection[9], and from the tenth minute onwards some 60 per cent of the protein synthesized can be accounted for by the proteins of the phage coat[7]. Surprisingly enough, protein synthesis after infection is not accompanied, as in growing cells, by a net synthesis of RNA[10]. Using isotopic labelling, however, Volkin and Astrachan[11] were able to demonstrate high turnover in a minor RNA fraction after phage infection. Most remarkable is the fact that this RNA fraction has an apparent nucleotide composition which corresponds to that of the DNA of the phage and is markedly different from that of the host RNA[11]. Recently, it has been shown that the bulk of this RNA is associated with the ribosomes of the infected cell[12].

Phage-infected bacteria therefore provide a situation in which the synthesis of protein is suddenly

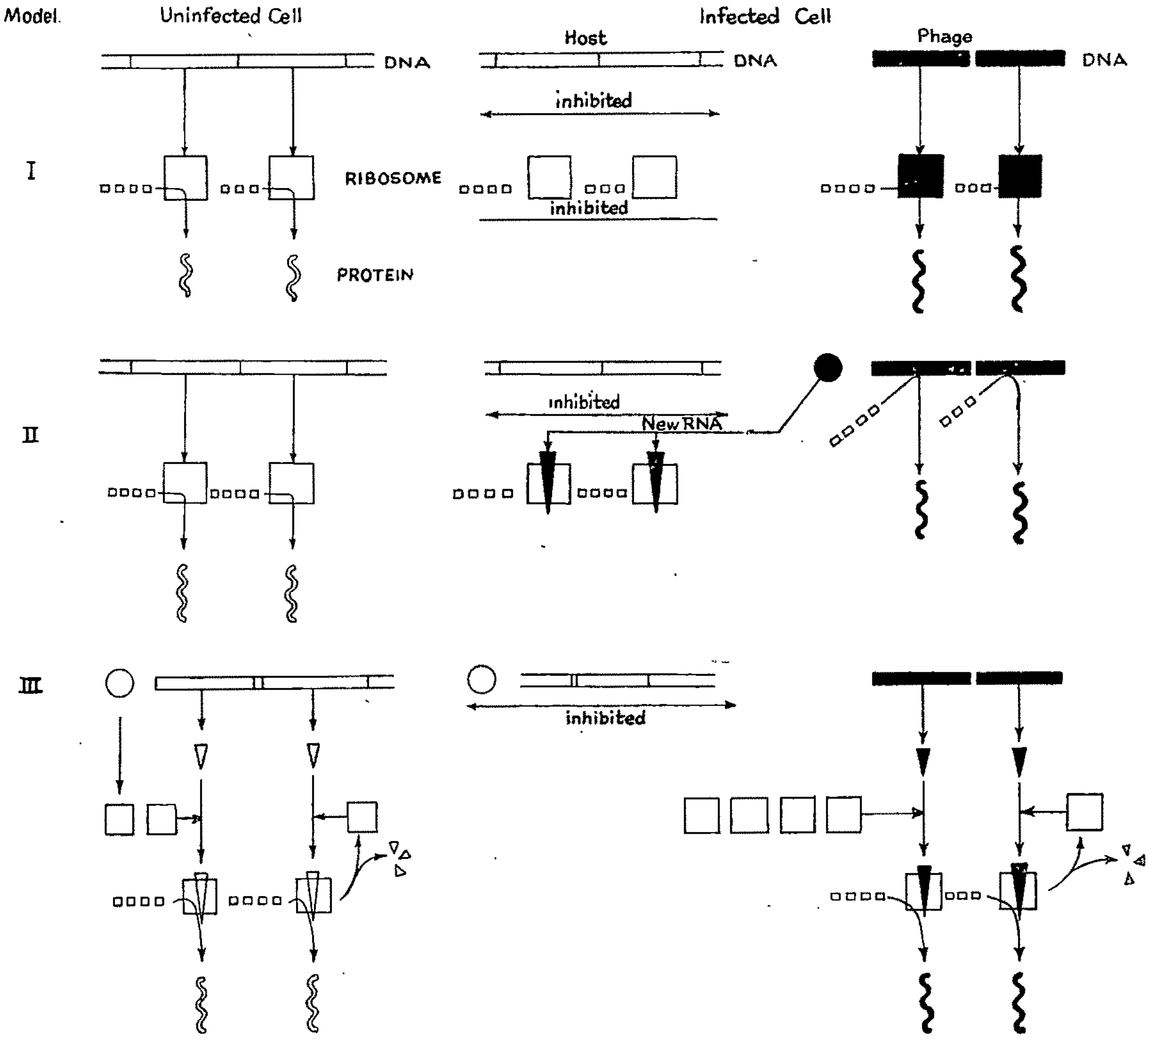

Fig. 1. Three models of information transfer in phage-infected cells

switched from bacterial to phage control and proceeds without the concomitant synthesis of stable RNA. *A priori*, three types of hypothesis may be considered to account for the known facts of phage protein synthesis (Fig. 1). Model I is the classical model. After infection the bacterial machinery is switched off, and new ribosomes are then synthesized by the phage genes. The *ad hoc* hypothesis has to be added that these ribosomes are unstable, to account for the turnover of RNA after phage infection. This is, in fact, the model favoured by Nomura *et al.*[12]. Model II assumes that in the particular case of phage the proteins are assembled directly on the DNA; the new RNA is a special molecule which enters old ribosomes and destroys their capacity for protein synthesis. At the same time, synthesis of ribosomes is switched off. Model III implies that a special type of RNA molecule, or 'messenger RNA', exists which brings genetic information from genes to non-specialized ribosomes and that the consequences of phage infection are two-fold: (*a*) to switch off the synthesis of new ribosomes; (*b*) to substitute phage messenger RNA for bacterial messenger RNA. This substitution can occur quickly only if messenger RNA is unstable; the RNA made after phage infection does turn over and appears, therefore, as a good candidate for the messenger.

It is possible to distinguish experimentally between these three models in the following way: Bacteria are grown in heavy isotopes so that all cell constituents are uniformly labelled 'heavy'. They are infected with phage and transferred immediately to a medium containing light isotopes so that all constituents synthesized after infection are 'light'. The distribution of new RNA and new protein, labelled with radioactive isotopes, is then followed by density gradient centrifugation[13] of purified ribosomes.

Density gradient centrifugation was carried out in a preparative centrifuge, and the ribosomes were stabilized by including magnesium acetate (0·01–0·06 *M*) in the cæsium chloride solution. Ribosomes show two bands, a heavier *A* band and a lighter *B* band, the relative proportions of which, for a given preparation, depend on the magnesium concentration used. The lower the magnesium concentration, the smaller the proportion of *B* band ribosomes and the larger the proportion of *A* band ribosomes.

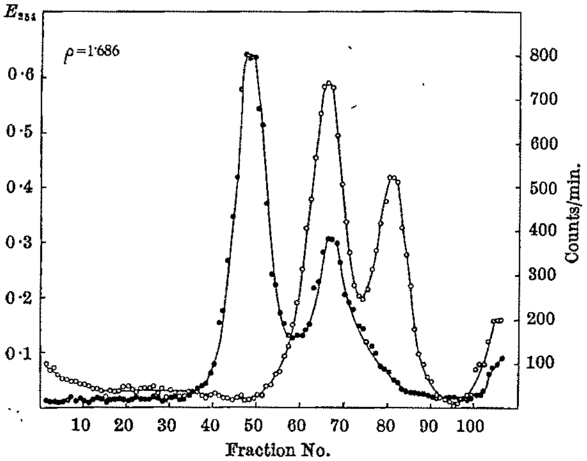

Fig. 2. Distribution of heavy and light ribosomes in a density gradient. *E. coli* B, grown in 5 ml. of a medium containing ^{15}N (99 per cent) and ^{13}C (60 per cent) algal hydrolysate and $^{32}PO_4$, were mixed with a fifty-fold excess of cells grown in nutrient broth, the ribosomes extracted by alumina grinding in the presence of 0·01 *M* Mg^{++} and purified by centrifugation. 1 mgm. of ribosomes was centrifuged in 3 ml. of cæsium chloride buffered to *p*H 7·2 with 0·1 *M tris* and containing 0·03 *M* magnesium acetate for 35 hr. at 37,000 r.p.m. in the *SW*39 rotor of the Spinco model *L* ultracentrifuge. After the run, a hole was pierced in the bottom of the tube and drops sequentially collected. Ultra-violet absorption at 254 mμ detects the excess of light ribosomes (○), ^{32}P counts detect the heavy ribosomes (●)

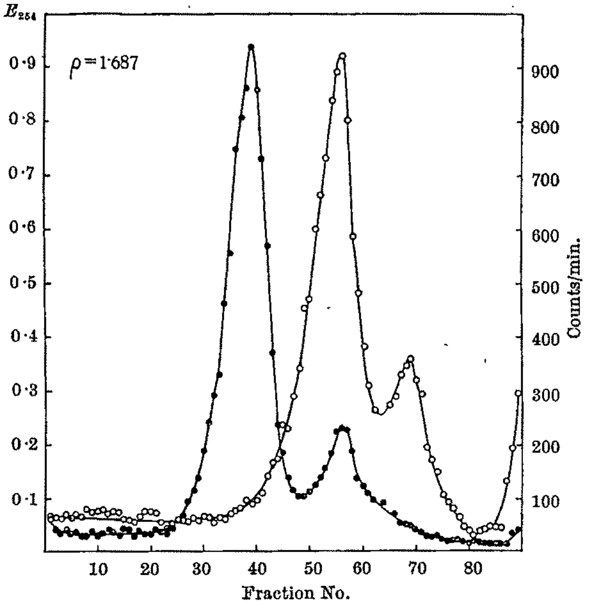

Fig. 3. Distribution of randomized heavy and light ribosomes in a density gradient. The mixture of $^{15}N^{13}C^{32}P$ and $^{14}N^{12}C^{31}P$ ribosomes was dialysed first for 18 hr. against 0·0005 *M* magnesium acetate in 0·01 *M* phosphate buffer *p*H 7·0, and then for 24 hr. against two changes of 0·01 *M* magnesium acetate in 0·001 *M tris* buffer *p*H 7·4. 1 mgm. of ribosomes was centrifuged for 38 hr. at 37,000 r.p.m. in cæsium chloride containing 0·03 *M* magnesium acetate. The drops were assayed for ultra-violet absorption (○) and ^{32}P content (●)

In order to show that there is no aggregation of ribosomes during preparation and density gradient centrifugation an experiment was carried out on ribosomes extracted from a mixture of $^{15}N^{13}C$ and $^{14}N^{12}C$ bacteria. The results are shown in Fig. 2, from which it can be seen that ribosomes of different isotopic compositions band independently and that there are no intermediate classes. The same preparation was then dialysed against low magnesium to dissociate the ribosomes into their 50 *S* and 30 *S* components and then against high magnesium to re-associate the sub-units[14]. This should have resulted in distributing heavy 30 *S* and 50 *S* subunits into mixed 70 *S* and 100 *S* ribosomes. Surprisingly enough, density gradient centrifugation of this preparation (Fig. 3) yields the same bands as found in the original ribosomes except for a decrease in the proportion of the *B* bands. This means that both bands contain units which do not undergo reversible association and dissociation and that the mixed 70 *S* ribosomes prepared by dialysis separate

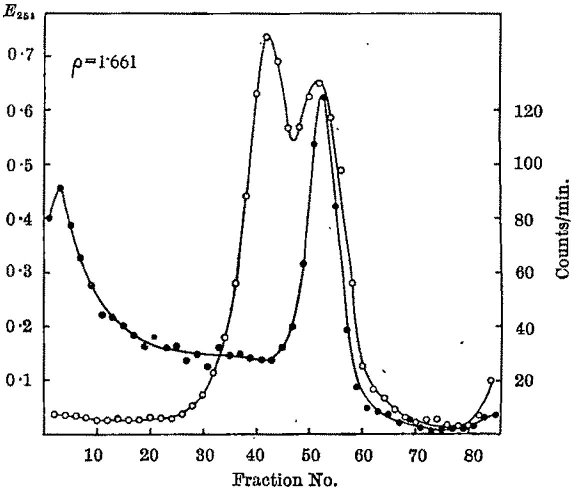

Fig. 4

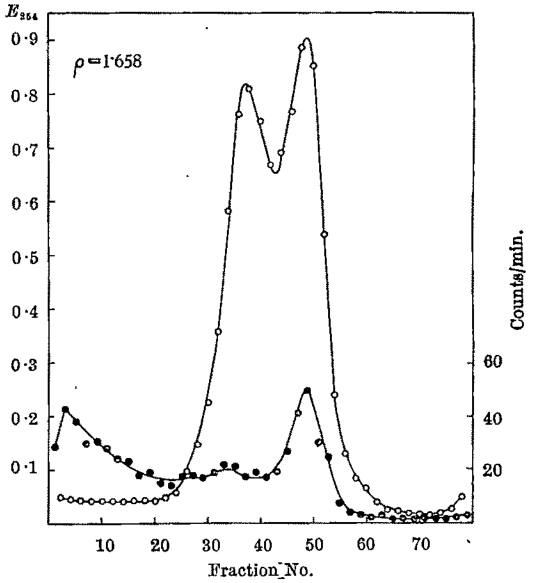

Fig. 5

Figs. 4 and 5. Distribution and turnover of RNA formed after phage infection. A 600 ml. culture of *E. coli B*6 (mutant requiring arginine and uracil) was infected with *T4D* (multiplicity 30) and fed ^{14}C-uracil (10 mc./m*M*) from third to fifth min. after infection. One half of the culture was removed and ribosomes prepared (Fig. 4). The other half received a two hundred-fold excess of ^{12}C-uridine for a further 16 min. and ribosomes prepared (Fig. 5). In both experiments approximately 3 mgm. of purified ribosomes were centrifuged for 42 hr. at 37,000 r.p.m. in cæsium chloride containing 0·05 *M* magnesium acetate. Alternate drops were collected in *tris*-magnesium buffer for ultra-violet absorption (○) and on to 0·5 ml. of frozen 5 per cent trichloroacetic acid. These tubes were thawed, 1 mgm. of serum albumin added, and the precipitates separated and washed by filtration on membrane filters for assay of radioactivity (●)

into their components in the density gradient. Other experiments to be reported elsewhere suggest that the *A* band is composed of free 50 *S* and 30 *S* ribosomes and that the *B* band contains undissociated 70 *S* particles.

The bulk of the RNA synthesized after infection is found in the ribosome fraction, provided that the extraction is carried out in 0·01 *M* magnesium ions[12]. We have confirmed this finding and have studied the distribution of the new RNA among the ribosomal units found in the density gradient. Fig. 4 shows that this RNA, labelled with ^{14}C-uracil, bands in the same position as *B* band ribosomes. There is no peak corresponding to the *A* band. In addition, there is radioactivity at the bottom of the cell. This is free RNA as its density is greater than 1·8, and, moreover, it must have a reasonably high molecular weight to have sedimented in the gradient. Lowering of the magnesium concentration in the gradient, or dialysing the particles against low magnesium, produces a decrease of the *B* band and an increase of the *A* band. At the same time, the radioactive RNA leaves the *B* band to appear at the bottom of the gradient. This shows that the uracil has labelled a species of RNA distinct from that of the bulk of *B* band ribosomes, since the specific activity of the RNA at the bottom of the cell is much higher than that of the *B* band. Fig. 5 shows that this RNA turns over during phage growth. There is a decrease by a factor of four in the specific activity of the *B* band after 16 min. of growth in ^{12}C-uridine. Similar results have been obtained using $^{32}PO_4$ as a label.

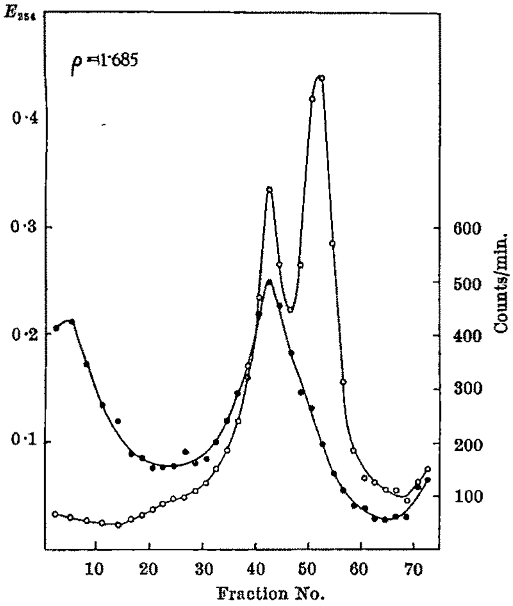

Fig. 6. RNA after isotope transfer in phage-infected cells. *E. coli* B grown in 10 ml. of ^{15}N (99 per cent) and ^{13}C (60 per cent) algal hydrolysate medium were starved in buffer, infected with *T*4 and growth initiated by addition of glucose and dephosphorylated broth ($^{14}N^{12}C$). $^{32}PO_4$ was fed from the second to seventh min. after infection. The culture was mixed with a fifty-fold excess of *E. coli* B grown in nutrient broth, infected in buffer and then grown for 7 min. in dephosphorylated broth medium. 1 mgm. of purified ribosomes was centrifuged for 36 hr. at 37,000 r.p.m. in cæsium chloride containing 0·03 *M* magnesium acetate. Ultra-violet absorption (○) detects the $^{14}N^{12}C^{31}P$ carrier, radioactivity (●) detects the new RNA in the heavy cells transferred to light medium

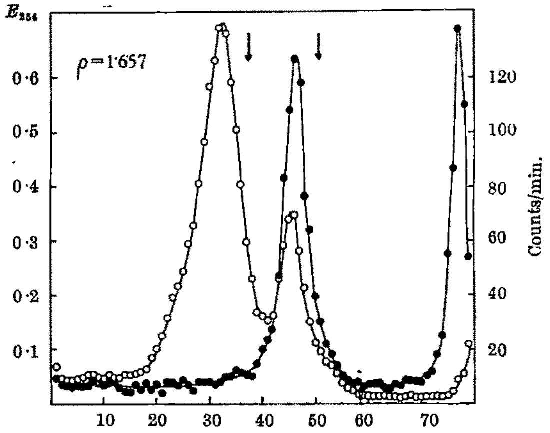

Fig. 7

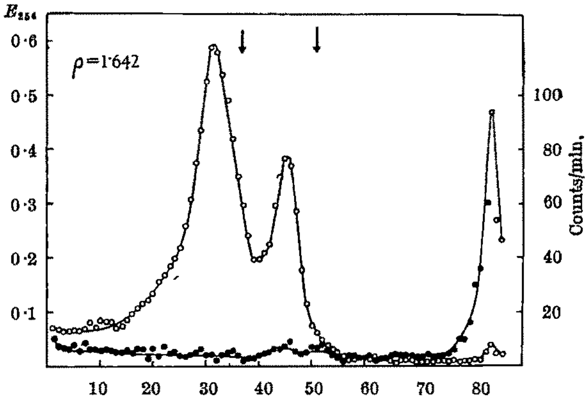

Fig. 8

Figs. 7 and 8. Distribution and turnover of newly synthesized protein in ribosomes of phage-infected cells after transfer. *E. coli* B grown in 600 ml. of a salt glucose medium containing $^{15}NH_4Cl$ (99 per cent) were starved in buffer, infected with *T*4 and transferred to $^{14}NH_4Cl$ medium. $^{35}SO_4$ was fed for the first 2 min. of infection and one half of the culture removed (Fig. 7). The other half received an excess of $^{32}SO_4$ and ^{32}S-methionine and growth was continued for a further 8 min. (Fig. 8). 1 mgm. of purified ribosomes was centrifuged for 39 hr. at 37,000 r.p.m. in cæsium chloride containing 0·05 *M* magnesium acetate. Drops were assayed for ultra-violet absorption (○) and for radioactivity (●). The arrows mark the expected positions for the peaks of ^{14}N *A* and *B* bands. The radioactivity at the top of the gradient is contaminating protein

These results do not distinguish between a messenger fraction and a small proportion of new ribosomes which are fragile in cæsium chloride and which are also metabolically unstable. In order to make the distinction, the experiment was carried out with an isotope transfer, in the following manner: Cells grown in a small volume of $^{15}N^{13}C$ medium were infected with *T* 4, transferred to $^{14}N^{12}C$ medium and fed $^{32}PO_4$ from the second to the seventh minute. They were mixed with a fifty-fold excess of cells grown and infected in $^{14}N^{12}C^{31}P$ medium. Fig. 6 shows that the RNA formed after infection in the heavy cells has a density greater than that of the *B* band of the carrier. Its peak corresponds exactly with the density of the *B* band of $^{15}N^{13}C$ ribosomes (Fig. 2) although it is skewed to lighter density, and its response to changing the magnesium concentration was that of a *B* band. There is no radioactive peak corresponding to the *B* band of the carrier: this means that no wholly new ribosomes are synthesized after phage infection. As already shown, the new RNA does not represent random labelling of *B* band ribosomes; therefore it con-

PHYSICS DEP

stitutes a fraction which is added to pre-existing ribosomes the bulk of the material of which has been assimilated before infection. This result conclusively eliminates model I.

To distinguish between models II and III an experiment was carried out to see whether pre-existing ribosomes participate in protein synthesis after phage infection. Cells were grown in ^{15}N medium, infected with phage, transferred to ^{14}N medium and fed $^{35}SO_4$ for the first 2 min. of phage growth. Fig. 7 shows that only the *B* band of pre-existing ribosomes becomes labelled with ^{35}S and there is no peak corresponding to a ^{14}N *B* band. All this label can be removed by growth in non-radioactive sulphate and methionine (Fig. 8). In this experiment, the incorporation of ^{35}S into the total extract was measured and the amount in the *B* band found to correspond to 10 sec. of protein synthesis. This is probably an over-estimate since it is unlikely that pool equilibration was attained instantaneously. This value corresponds quite closely with the ribosome passage time of 5–7 sec. for the nascent protein in uninfected cells[15]. In addition, electrophoresis of chymotrypsin digests of *B* band ribosomes shows that the radioactivity is already contained in a variety of peptides. It would therefore appear that most, if not all, protein synthesis in the infected cell occurs in ribosomes. The experiment also shows that pre-existing ribosomes are used for synthesis and that no new ribosomes containing stable sulphur-35 are synthesized. This result effectively eliminates model II.

We may summarize our findings as follows: (1) After phage infection no new ribosomes can be detected. (2) A new RNA with a relatively rapid turnover is synthesized after phage infection. This RNA, which has a base composition corresponding to that of the phage DNA, is added to pre-existing ribosomes, from which it can be detached in a cæsium chloride gradient by lowering the magnesium concentration. (3) Most, and perhaps all, protein synthesis in the infected cell occurs in pre-existing ribosomes.

These conclusions are compatible only with model III (Fig. 1), which implies that protein synthesis occurs by a similar mechanism in uninfected cells. This, indeed, appears to be the case: exposure of uninfected cells to a 10-sec. pulse of $^{32}PO_4$ results in labelling of the RNA in the *B* band and not in the *A* band of ribosomes, and this RNA can be detached from the ribosomes by lowering the concentration of magnesium ions. Similarly the nascent protein can be labelled by a short pulse of $^{35}SO_4$; it is located in the *B* band and most of the label is removed by growth in non-radioactive sulphate. In contrast to what was observed in infected cells, residual stable radioactivity is found in both bands, reflecting the synthesis of new ribosomes.

In order to act as an intermediate carrier of information from genes to ribosomes, the messenger has to fulfil certain prerequisites of size, turnover and nucleotide composition. In the accompanying article, Gros *et al.*[16] have analysed the distribution of pulse-labelled RNA in sucrose gradients. They have shown that in uninfected cells there is an RNA fraction which has a rapid turnover and which can become attached reversibly to ribosomes depending on the magnesium concentration. The *T*2 phage-specific RNA shows the same behaviour and both are physically similar, with sedimentation constants of 14–16 *S*. We have carried out similar experiments[17] independently and our results confirm their findings. These suggest that, although the messenger RNA is a minor fraction of the total RNA (not more than 4 per cent), it is not uniformly distributed over all ribosomes, and may be large enough to code for long polypeptide chains. When ribosomes, from phage-infected cells labelled with $^{32}PO_4$ for five min., are separated by centrifugation in a sucrose density gradient[18] containing 0·01 *M* Mg^{++}, most of the messenger is found in 70 and 100 *S* ribosomes, contrary to previous reports[12]. When the magnesium concentration is lowered, the radioactivity is found in three peaks of roughly equal amount: (1) corresponding to a small residual number of 70 *S* ribosomes; (2) corresponding to 30 *S* ribosomes; (3) a peak of very high specific activity at 12 *S*. Separation of the RNA extracted from such ribosomes with detergent shows all the counts to be located in a peak at 12 *S*, skewed towards the heavier side. These results suggest that the messenger is heterogeneous in size and may have a minimum molecular weight of about ¼ to ½ million. Similar results have been obtained in uninfected cells[17].

The undissociable 70 *S* ribosomes are enriched for messenger RNA over the total ribosomes of this type and it has been shown that they are also enriched for the nascent protein[17]. These ribosomes have been called "active 70 *S*" ribosomes, by Tissières *et al.*[19], and they appear to be the only ribosomes which preserve the ability to synthesize protein *in vitro*. This leads one to suspect that there is a series of successive events involved in protein synthesis, and that at any time we investigate a temporal cross-section of the process.

The exact determination of the rate of turnover of the messenger RNA should give information about the process of protein synthesis. This might be stoichiometric, in the sense that each messenger molecule functions only once in information transfer before it is destroyed. Its rate of turnover should then be the same as that of the nascent protein; but experiments to test this idea have been limited by difficulties in pool equilibration with nucleotide precursors.

It is a prediction of the hypothesis that the messenger RNA should be a simple copy of the gene, and its nucleotide composition should therefore correspond to that of the DNA. This appears to be the case in phage-infected cells[11,20], and recently Ycas and Vincent[21] have found a rapidly labelled RNA fraction with this property in yeast cells. If this turns out to be universally true, interesting implications for coding mechanisms will be raised.

One last point deserves emphasis. Although the details of the mechanism of information transfer by messenger are not clear, the experiments with phage-infected cells show unequivocally that information for protein synthesis cannot be encoded in the chemical sequence of the ribosomal RNA. Ribosomes are non-specialized structures which synthesize, at a given time, the protein dictated by the messenger they happen to contain. The function of the ribosomal RNA in this process is unknown and there are also no restrictions on its origin in the cell: it may be synthesized by nuclear genes or by enzymes or it may be endowed with self-replicating ability.

This work was initiated while two of us (S. B. and F. J.) were guest investigators in the Division of

Biology, California Institute of Technology, Pasadena, during June 1960. We would like to thank Profs. G. W Beadle and M. Delbrück for their kind hospitality and financial support.

UNSTABLE RIBONUCLEIC ACID REVEALED BY PULSE LABELLING OF *ESCHERICHIA COLI*

By Drs. FRANCOIS GROS and H. HIATT

WHEN *Escherichia coli* cells are infected with *T* even bacteriophage particles, synthesis of host proteins stops[1], and much if not all new protein synthesis is phage specific[2]. This system thus provides an ideal model for observing the synthesis of new proteins following the introduction of specific DNA. In particular, we should expect the appearance of phage-specific RNA, since it is generally assumed that DNA is not a direct template for protein synthesis but that its genetic information is transmitted to a specific sequence of bases in RNA. It was thus considered paradoxical when it was first noticed[3] that, following infection by the *T* even phages, net RNA synthesis stops even though protein synthesis continues at the rate of the uninfected bacterium. This could mean that DNA sometimes serves as a direct template for protein synthesis. Alternatively, net RNA synthesis may not be necessary so long as there exists the synthesis of a genetically specific RNA that turns over rapidly. This possibility was first suggested by experiments of Hershey[4], who, in 1953, reported that *T*2 infected cells contain a metabolically active RNA fraction comprising about 1 per cent of the total RNA. Several years later, Volkin and Astrachan[5] reported that this metabolic RNA possessed base ratios similar, if not identical (considering uracil formally equivalent to thymine), to those of the infecting *T*2 DNA. By 1958 they[6] extended their observation to *T*7 infected cells, where again the RNA synthesized after phage infection had base ratios similar to those of the phage DNA.

During these years, evidence[7] accumulated that the sites of much, if not all, protein synthesis are the ribosomal particles, and it was thought most likely that ribosomal RNA was genetically specific, with each ribosome possessing a base sequence which coded for a specific amino-acid sequence (one ribosome–one protein hypothesis). Direct verification of this hypothesis was lacking, and its proponents[8] were troubled by the fact that, except for phage-specific RNA, it was impossible to find any correlation within a given organism between the base ratios of DNA and RNA. Moreover, there was no evidence that phage-specific RNA was ribosomal RNA.

Nomura, Hall and Spiegelman[9] have recently discovered that following *T*2 infection there is no synthesis of typical (see below) ribosomal RNA and that the phage-specific RNA sediments at a slower rate (8*s*) than ribosomal RNA (16*s* and 23*s*). The genetic information for the synthesis of phage-specific proteins does not reside in the usual ribosomal RNA. Instead, if we assume that the synthesis of phage-specific proteins also occurs on ribosomes, then the phage-specific RNA might be viewed as a 'messenger' (to use the terminology of Monod and Jacob[10]) which carries the genetic information to the ribosomes. Furthermore, unless we postulate that there exist two different mechanisms for protein synthesis, there should also exist within uninfected normal cells RNA molecules physically similar to the phage-specific RNA and having base ratios similar to its specific DNA.

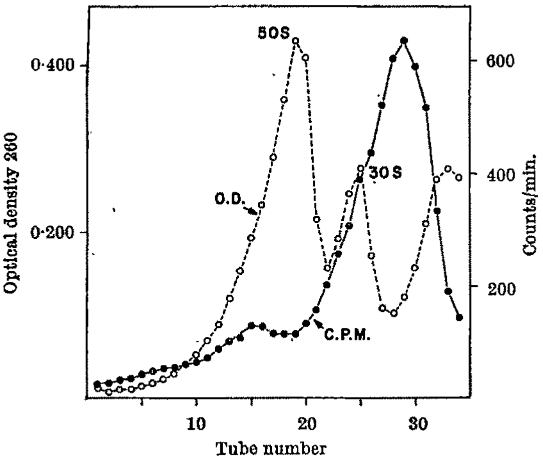

Fig. 1. Sedimentation of pulse-labelled 10^{-4} Mg^{2+} extract. 1 ml. of a crude extract labelled by a 20-sec. pulse of ^{14}C-uracil and made in 10^{-4} *M* Mg^{2+} and 5×10^{-3} *tris* buffer (*p*H 7·4) was carefully layered on top of a 24-ml. sucrose gradient (5–20 per cent) in a Spinco *SW*25 swinging-bucket tube. It was spun 2 hr. 45 min. at 25,000 r.p.m. at 4° C. The tube bottom was then punctured and 10 drop samples taken to measure 2600 Å. absorption (2 drops) and the radioactivity in 5 per cent trichloracetic acid precipitates (8 drops). All points were counted to at least 1,000 counts

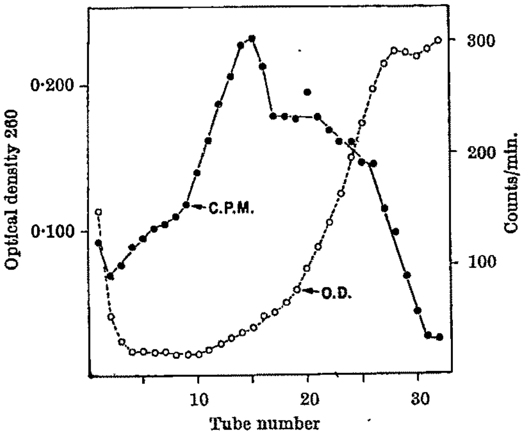

Fig. 2. Sedimentation of pulse-labelled 10^{-4} Mg^{2+} extract, long run. An extract as in Fig. 1 run for 11 hr. at 25,000 r.p.m., 15° C., on a sucrose gradient. Drop collection and radioactivity measurements were made as described in Fig. 1

Here we present evidence that RNA molecules physically similar to phage-specific RNA exist in normal *E. coli* cells and that, under suitable ionic conditions, they are associated with ribosomal particles.

Experimental plan. Most (80–85 per cent) RNA in actively growing *Escherichia coli* cells is found in ribosomal particles composed of 64 per cent RNA and 36 per cent protein[11]. There are two sizes[12] of ribosomal RNA, 16*s* (molecular weight = $5 \cdot 5 \times 10^5$) and 23*s* (molecular weight = $1 \cdot 1 \times 10^6$). The 16*s* RNA is derived from both 30*s* and 50*s* ribosomes, while 23*s* RNA is only found in 50*s* ribosomes. The other principal (10–15 per cent) form of RNA in *E. coli* is soluble RNA (now more appropriately called transfer RNA), which functions in the movement of activated amino-acids to the ribosomes. At least 20 (one for each amino-acid) different transfer RNA molecules exist[13], all of which have molecular weights about 25,000 and sedimentation constants of 4*s*.

Collectively, ribosomal and transfer RNA comprise at least 95 per cent of *E. coli* RNA. Thus messenger RNA, if present, can amount to at most only several per cent of the total RNA. Now if the messenger were stable, only a corresponding fraction of newly synthesized RNA could be messenger RNA; the great majority of new RNA being the metabolically stable ribosomal and transfer RNA's. If, however, messenger RNA is turning over (as is suggested by the original Hershey experiments) then a much larger fraction of newly made RNA must be messenger. For example, if the messenger functions only once for the synthesis of a single protein molecule, its lifetime might be only several seconds. In this event, if we look at the RNA synthesis occurring during a very short interval, then most of the newly synthesized RNA would be messenger even though this fraction may comprise only 1 per cent of the total RNA.

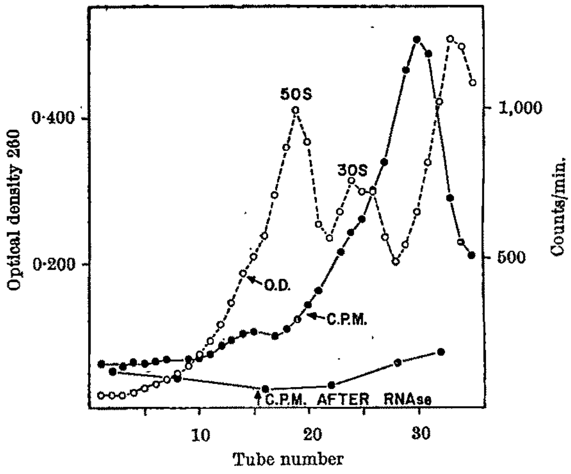

Fig. 3. Sedimentation of *T*2-infected 10^{-4} Mg^{2+} extract. An extract in 10^{-4} Mg^{2+} of cells infected with *T*2 at a multiplicity of 20 and labelled with phosphorus-32 between the second and fifth minutes after infection. Run as in Fig. 1. Several samples were treated with ribonuclease (10 γ/c.c.) to determine the background of label not in RNA

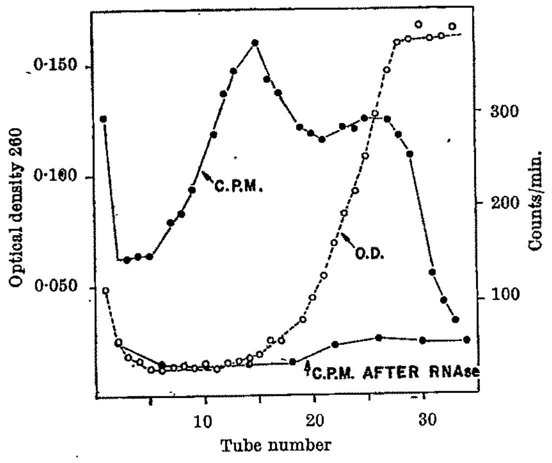

Fig. 4. Sedimentation of *T*2-infected 10^{-4} Mg^{2+} extract, long run. An extract as in Fig. 3 run for 11 hr. at 25,000 r.p.m. 20° C. Measured as in Fig. 1

We have therefore exposed *E. coli* cells to short pulses (10–20 sec. at 25° C. where the time of generation is about 90 min.) of radioactive RNA precursors (^{32}P or ^{14}C-uracil), rapidly chilled the cells with crushed ice and *M*/100 azide, prepared cell-free extracts by alumina grinding, added deoxyribonuclease at 5γ/ml., and examined the newly made RNA using the sucrose-gradient centrifugation technique[14]. In some experiments ^{14}C-uracil was given to cells of a pyrimidine-requiring mutant (*B*148) which was briefly starved (30 min. at 25° C.) for uracil. No difference has been seen between the properties of RNA labelled in these two ways. Starved cells incorporate more radioactivity, and they were used in most of the experiments reported below.

Results. Radioactive uracil (or phosphorus-32) is incorporated in RNA within several seconds after addition of the isotope. The RNA labelled by 10–20 sec. pulses is stable at 4° C. in cell-free extracts where ribonuclease and polynucleotide phosphorylase are not active. Traces (1γ/ml.) of ribonuclease degrade it under conditions where RNA in ribosomes is untouched. This suggests that it exists less protected than bound ribosomal RNA. Similarly, addition of phosphate permits the polynucleotide phosphorylase[15] in the cell extract to degrade preferentially pulse-labelled RNA. Our experiments thus as a matter of routine avoid the use of phosphate buffers.

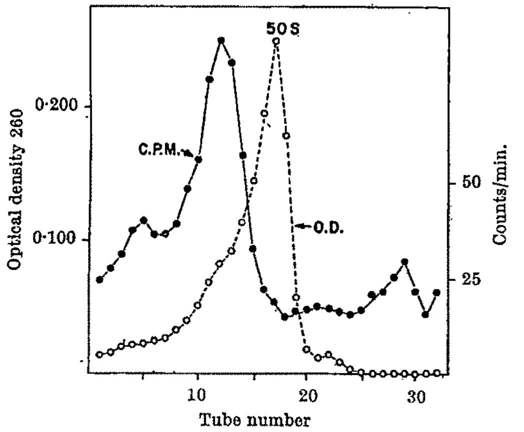

Fig. 5. Pulse-labelled active 70*s* ribosomes in 10^{-4} Mg^{2+}. An extract of cells labelled with a 20-sec. pulse of ^{14}C-uracil, made in 10^{-4} *M* Mg^{2+}, was purified by three 1 hr. centrifugations at 40,000 r.p.m. in 10^{-4} *M* Mg^{2+}, 5×10^{-3} *M tris* (*p*H 7·4). The resuspended pellet was run as for Fig. 1

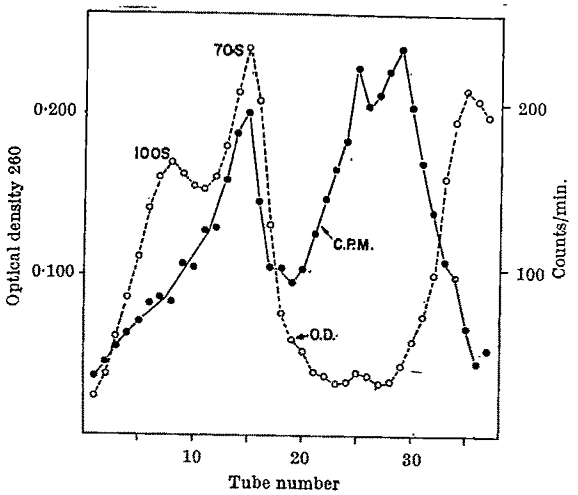

Fig. 6. Sedimentation of pulse-labelled 10^{-4} Mg^{2+} extract in 10^{-2} *M* Mg^{2+}. Magnesium was added to the 10^{-4} Mg^{2+} extract of Fig. 1 to bring it to 10^{-2} *M* Mg^{2+}. The sample was then run on a sucrose gradient in 10^{-2} *M* Mg^{2+}, 5×10^{-3} *M tris*, for 2 hr. 45 min. The measurements were made as described for Fig. 1

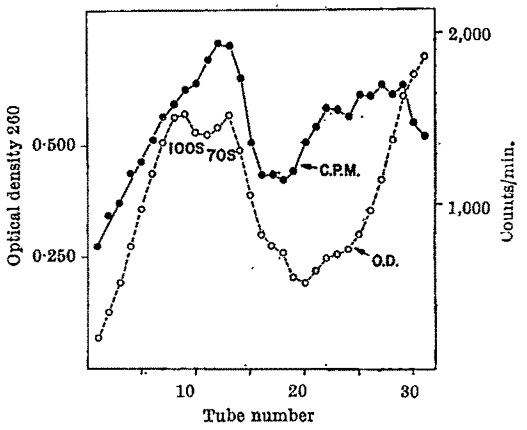

Fig. 7. Sedimentation of *T*2-infected 10^{-2} Mg^{2+} extract. An extract in 10^{-2} *M* Mg^{2+} of cells infected with *T*2 and labelled with phosphorus-32 from the second to the fifth minutes after infection. Run on a sucrose gradient in 10^{-2} *M* Mg^{2+} for 2 hr. 45 min. at 25,000 r.p.m. Drop collection and radioactivity measurements as for Fig. 1

Figs. 1 and 2 show how RNA labelled by a 20-sec. exposure of uninfected cells to ^{14}C-uracil sediments in a sucrose gradient. The cell-free extract contains 10^{-4} *M* magnesium ions in which 30*s* and 50*s* ribosomes predominate. The majority of the radioactivity is not associated with ribosomes but moves with a 14–16*s* peak. There is also RNA which moves more slowly, in addition to a faster forward fraction moving at 70*s*. The slower sedimenting fraction shows up more clearly in the longer centrifugation shown in Fig. 2. Here a sharp 14–16*s* component is seen together with material sedimenting at 4–8*s*. Figs. 3 and 4 illustrate experiments with extracts from *T*2 infected cells exposed to phosphorus-32 from 2 to 5 min. after infection. They are similar, if not identical, to Figs. 1 and 2. Both have a major 14–16*s* component, a slower trailing fraction, and about 10 per cent of the material moving at 70*s*. The 70*s* component can be purified by three 1-hr. centrifugations at 40,000 r.p.m. with 10^{-4} *M* magnesium ions to concentrate the faster-moving ribosomes of Fig. 1. Fig. 5 shows the purified ribosomes consisting largely of 50*s* particles together with a now visible 70*s* component. The radioactivity, however, sediments as 70*s* ribosomes.

Still more label is attached to 70*s* particles when extracts are made in 10^{-2} *M* magnesium ions or when additional magnesium ions are added to 10^{-4} *M* extracts. Figs. 6 and 7 again illustrate the parallel appearance of normal and phage-infected extracts. About 30 per cent of label sediments with the 70*s* and 100*s* ribosomes, with the specific activity of 70*s* ribosomes generally greater than that of 100*s* ribosomes. When slightly lower concentrations of magnesium ions are used to give similar amounts of 30*s*, 50*s* and 70*s* ribosomes, label is specifically associated only with 70*s* particles and no label is in 50*s* ribosomes. The radioactivity sedimenting about

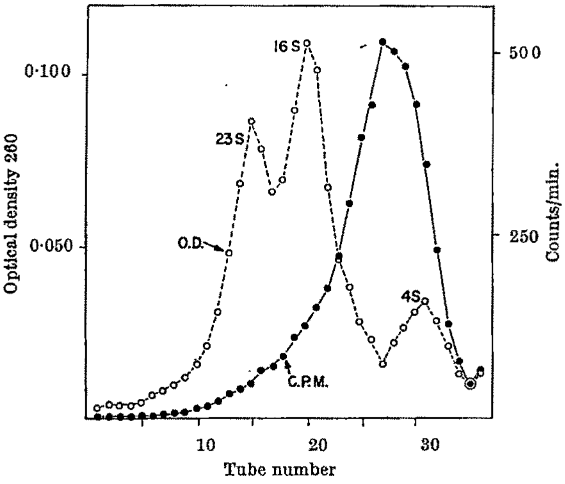

Fig. 8. Sedimentation of pulse-labelled RNA. An extract of cells labelled with a 20-sec. pulse of ^{14}C-uracil was treated with 0·5 per cent sodium lauryl sulphate ('Duponol') and then extracted three times with phenol. The RNA was then precipitated three times with alcohol and finally resuspended in 10^{-2} acetate buffer (*p*H 5·1). The RNA was run on a sucrose gradient, containing 10^{-2} acetate (*p*H 5·1) and M/10 sodium chloride, for 10 hr. at 25,000 r.p.m., 4° C. The drop collection and radioactivity measurements were made as described for Fig. 1

30*s* shows a very broad peak (20–40*s*) and it is probable that high concentrations of magnesium ions cause the 14–16*s* material either to aggregate or to assume a more compact shape.

Purified RNA, prepared by sodium lauryl sulphate ('Duponol') and phenol treatment of 20-sec. pulse extracts, sediments as shown in Fig. 8. Again the pattern is identical to that of labelled RNA from *T*2 infected cells (Fig. 9). Most newly synthesized RNA has a sedimentation constant about 8*s*; there is no appreciable synthesis of typical 16*s* or 23*s* ribosomal RNA. Since much new RNA in crude extracts moves at 14–16*s*, we considered the possibility that pulse-RNA is more sensitive than ribosomal RNA to degradation during the phenol extractions. Sodium lauryl sulphate (0·5 per cent) alone was therefore added to labelled crude extracts. This detergent treatment[12] both separates RNA from protein and completely inhibits action of the latent ribonuclease[16] release upon ribosome breakdown. When such treated extracts were run in sucrose gradients, the results were identical to those with phenol-prepared RNA.

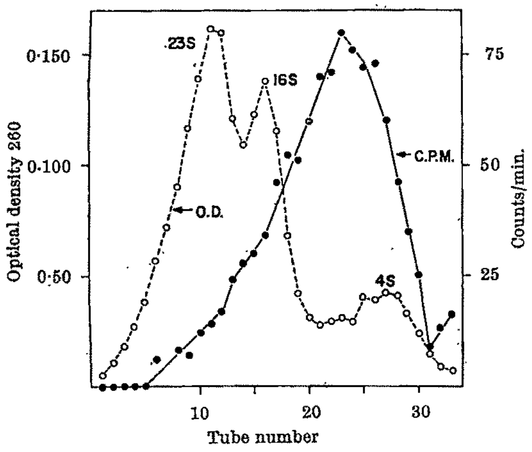

Fig. 9. Sedimentation of *T*2-specific RNA. RNA of cells infected with *T*2 and labelled with phosphorus-32 between the second and fifth minute, prepared and run as described for Fig. 8

The turnover of pulse-RNA is seen in chase experiments in which an excess of cold uracil is added after a 10-sec. ^{14}C-uracil pulse. After 15 min. at 37° C., all the label in crude extracts leaves the 14–16*s* component and is incorporated in the metabolically stable ribosomal and soluble RNA. In our kinetics experiments, the 16*s* RNA molecules always become labelled before appreciable labelling of 23*s* RNA molecules; likewise the 30*s* ribosomes become labelled before the 50*s* ribosomes. Since the base ratios of 16*s* and 23*s* chains are identical[17], it is likely that the 23*s* molecules form from two 16*s* chains.

Discussion. Our pulse experiments show that uninfected cells contain unstable RNA with sedimentation constants and attachment properties similar to those of *T*2-specific RNA. It is tempting to believe that these unstable molecules convey genetic information and are 'messenger' RNA. Complete homology with phage-specific RNA, however, will be demonstrated only if the base ratios of pulse-RNA are those of DNA. Unfortunately, in *E. coli*, the DNA base ratios do not differ greatly from ribosomal RNA, and as yet the base ratios of *E. coli* pulse-RNA are not precisely known. But we do have preliminary results (Hayes, D., and Gros, F., unpublished results) from *Staphylococcus aureus* which indicate an RNA component rapidly turning over and possessing DNA-like base ratios. Moreover, in yeast, there is also reported an unstable RNA resembling DNA in base composition[18]. We thus believe that our current measurements with *E. coli* will extend this fact and rule out the possibility that pulse-RNA is a precursor sub-unit from which ribosomal RNA is built up.

A messenger role for pulse-RNA fits nicely with its specific attachment to 70*s* ribosomes, the sites of protein synthesis[19]. Our experiments reveal two types of attachment. In one, the labelled RNA moves reversibly on or off 70*s* ribosomes depending on the concentration of magnesium ions. The second type of attachment binds pulse-RNA irreversibly to 'active' 70*s* ribosomes. These are 70*s* ribosomes which do not break apart with 10^{-4} M magnesium ions and which Tissières *et al.*[19] have shown to be the principal, if not sole, site of *in vitro* protein synthesis. They can be washed several times with 10^{-4} M magnesium ions without losing their ability to act in protein synthesis, and so they must have their genetic RNA firmly attached. It is reassuring that they can contain pulse-RNA. At least two stages, one reversible, the other not, thus exist in active 70*s* formation.

So far as we can tell, pulse-RNA, when associated with ribosomes, sediments at exactly 70*s* or 100*s*. Many experiments show that the label sediments neither faster nor slower than ordinary ribosomes. We find it hard to believe that the 14–16*s* RNA component which exists in 10^{-4} M magnesium ion extracts can combine with 70*s* or 100*s* ribosomes without altering their rate of sedimentation. Another possibility is that with 10^{-2} M magnesium ions, the 14–16*s* component assumes a more compact configuration similar to that of the RNA in a 30*s* particle. It could then associate with a free 50*s* ribosome to form a 70*s* ribosome which is transformed to an active 70*s* ribosome.

In conclusion, we state our findings: bacteria contain an RNA component turning over rapidly which is physically distinct from ribosomal or soluble (transfer) RNA. This fraction behaves, in its range of sedimentation constants and its attachment to ribosomes in high magnesium ion concentrations, exactly as does the phage-specific RNA made after *T*2 infection. Furthermore, it is associated with the active 70*s* ribosomes, the site of protein synthesis.

Our working hypothesis is that no fundamental difference exists between protein synthesis in phage-infected and uninfected bacteria. In both cases typical ribosomal RNA does not carry genetic information, but has another function, perhaps to provide a stable surface on which transfer RNA's can bring their specific amino-acids to the messenger RNA template.

These experiments were initiated when F. Gros was visiting the Biological Laboratories (May–August 1960). The pyrimidine-requiring strain *B*148 was kindly provided by Dr. Martin Lubin. The financial support of the National Science Foundation and the National Institutes of Health is gratefully appreciated.

DR. W. H. FITTON, F.R.S.

By JOAN M. EYLES

WILLIAM HENRY FITTON, physician and geologist, died in London on May 13, 1861, at the age of eighty-one. In an obituary notice, Sir Roderick Murchison, director-general of the Geological Survey, described him as "truly one of the British worthies who have raised modern geology to its present advanced position".

Fitton, of English descent, was born and brought up in Dublin and his proficiency in the classics enabled him to gain, in 1798, the Senior Scholarship of Trinity College. Even then he was a fossil collector, a hobby which brought him into the hands of the military on suspicion of being a rebel. In 1808, he went to Edinburgh to study medicine, and there attended the geological lectures of Robert Jameson, who was responsible for stimulating an interest in science and natural history in many young men at that time. Fitton graduated M.D. at Edinburgh in 1810, but continued to study medicine and chemistry in London until 1812. In that year he moved to Northampton, where he was in practice until 1820. Then marriage to a lady of considerable means enabled him to give up his practice and return to London, where his house soon became a regular meeting place for men of science and, in particular, geologists.

Fitton did not become a Fellow of the Geological Society until 1816, but his first geological paper, "On the Geological Structure of the Vicinity of Dublin", appeared in 1811 in the first volume of the Society's *Transactions*. In 1817 he contributed to the *Edinburgh Review* the first of a number of reviews, often lengthy, of geological works, which are noteworthy for the valuable information they contain on the history and progress of geology. These may still be consulted with profit by the historian of geology, for Fitton was widely read, had a clear analytical mind, and wrote with the facility of a classical scholar. Secretary of the Geological Society during 1822–24, he was elected president in 1827, and during his term of office introduced an important innovation, the publication of the *Proceedings* of the Society, of which the first number appeared in April 1827. In this publication the presidential addresses were published, Fitton's being the first to appear, and thus began that valuable annual series in which for many years the progress of geology was reviewed. Fitton was also instrumental in appointing, as curator and librarian, in 1829, William Lonsdale, a gifted palæontologist, who served the Society until 1842.

The geological work for which Fitton is best remembered, however, is his elucidation of the stratigraphy of the beds lying between the Kimmeridge Clay and the Chalk, that is, of the upper part of the Jurassic and the Lower Cretaceous. The succession comprises limestones, clays and sandstones, some marine and some fresh-water. During the course of a prolonged study of these beds in both the south-east of England and north-east France, he was able to establish the correct order of succession, a major advance in British stratigraphy. For these researches he received the Wollaston Medal of the Geological Society in 1852.

Fitton was elected Fellow of the Royal Society in 1815, and was also Fellow of the Linnean, Astronomical and Royal Geographical Societies.

OBITUARIES

Prof. Thomas Alan Stephenson, F.R.S.

Marine biologists in many lands will learn with sorrow of the death on April 3, at the age of sixty-three, of Prof. Thomas Alan Stephenson, for he had travelled widely and visited many ocean shores. Alan Stephenson's first interest was sea anemones, a group of animals which no doubt appealed to his artistic nature, and this culminated in the beautifully illustrated Ray Society monographs on British sea anemones which appeared in 1928 and 1935. He was on the staff of the Department of Zoology at University College, London, during 1922–30, and in 1923 made a short investigation for the States of Guernsey on the biology of the ormer, *Haliotis*, with the view of legislation to check the noticeable decrease in supply.

In 1928 he joined the Great Barrier Reef Expedition under C. M. Yonge and led the shore party concerned with the ecological investigations on the reefs. His knowledge of anemones made him most suitable for this expedition, and he naturally devoted much time to the corals themselves, making also valuable observations on growth. But his wider interest in shore ecology found full scope in a general study of reef ecology, on which one of his joint papers with his wife, G. Tandy and M. Spender, will have lasting value as evidence of the state of Low Isles in that year. It has already formed the basis of two later small-scale surveys.

In 1930, Stephenson was elected to the chair of zoology in the University of Cape Town. It was then that he developed his grand idea of the comparison of shore faunas on a world-wide scale. Our knowledge of the distribution of the intertidal fauna and flora had been restricted to detailed surveys at isolated points either in easy reach of marine laboratories or at places visited by expeditions. Stephenson was the first to organize a continuous survey along a great length of coast and its value lay in the fact that the same people saw the whole length of coast so that their observations were as comparable as possible.

This first great survey, over a period of ten years, extended from Port Nolloth on the west coast of Africa, round the Cape, to Durban on the east coast. It thus covered regions in the south Atlantic, the Southern and Indian Oceans, and extended through a range of climates as well as areas influenced by different ocean currents. The work was done with all his usual exactitude, and the correct identification of species was ensured so far as possible. The great series of papers produced by Stephenson and his colleagues will remain as a lasting memorial to a unique zoologist and as a reference point for all time. It was then that he discerned the underlying simplicity of the zonation patterns on the shore.

In 1940, he was appointed professor of zoology in the University of Wales at Aberystwyth, where he had been a student, and here he continued to inspire research on shore ecology. But every opportunity was still taken to continue his chief aim of seeing for himself as much of the coastline of the world as possible. With his wife Anne, who was always his constant and devoted collaborator, he explored the coasts of North America and of Bermuda. He was to have visited the Mediterranean this summer.

It was Alan's hope to write a book bringing together all his vast knowledge, and it is sad that he cannot now do this. But in fact a great deal has been published and is available to the world and the pioneering has been accomplished. The outburst of interest in marine science is ensuring that many more shores are being surveyed. The stimulus has been given and the standard set by Stephenson and his concept of three universal intertidal zones is being confirmed.

All Stephenson's work was characterized by its extreme finish, and everywhere could be seen his meticulous care for detail. But as well as being a first-class naturalist he was also an artist. His paintings of marine animals and plants are exquisite portrayals and their composition emphasizes his deep artistic appreciation and disclosure of pattern and rhythm, so beautifully exemplified in his little book on *Seashore Life and Pattern*.

The deepest sympathy of their many friends will go out to his wife in her bereavement.

F. S. Russell

Dr. Daphne Atkins

Dr. Daphne Atkins, a familiar figure to workers at the Plymouth Laboratory during the past 35 years, died on March 1. She was born on March 4, 1896, at Oxted, Surrey, the daughter of N. E. W. and Elisa Atkins. She was educated at the Kent County School for Girls, Tunbridge Wells, and from there went on to Bedford College, London, where she took her degree, in zoology and geology, in the early nineteen twenties.

Her first visit to Plymouth was probably in 1922 when I well remember her as a fellow student at the Easter class. After graduation she was soon to return to Plymouth where, supported initially by a series of research grants, she continued to work for much of the rest of her life. Her only notable period of absence was during and for some time after the War when she returned to Oxted to care for her aged parents.

She made major contributions to our knowledge of marine invertebrates. She observed the living animal, she studied its anatomy by dissection and in sections, in exact detail she followed the course of the ciliary currents concerned with respiration, feeding and cleansing in bivalve molluscs, polyzoans and brachiopods. She published her conclusions in admirably presented and most beautifully illustrated papers. These must have numbered at least forty and were largely published in the *Journal of the Marine Biological Association*, the *Quarterly Journal of Microscopical Science* and the *Proceedings of the Zoological Society of London.*

Her earliest research, suggested by J. H. Orton, on the moulting stages of pea-crabs (*Pinnotheres*) was published in 1927. While this led to further work on post-embryonic development, it had very different and far-reaching side issues. These included accounts of a fungal infection and of an entoniscid (Isopod) parasite on *Pinnotheres*, examples of contributions to parasitology which included descriptions of orthonectid, rhabdocœl and copepod parasites in bivalves.

Observing the effects of *Pinnotheres* on the gills of *Mytilus*, she noted that the damage caused led to the appearance of secondary or supernumerary food grooves with an associated reversal of beat in the adjacent frontal cilia. This led to further work on abnormal gills and then on regeneration. These are very valuable papers containing information which could very suitably form the groundwork of further important studies. In the case of their author they led to a series of eight papers "On the Ciliary Mechanisms and Interrelationships of Lamellibranchs" published between 1936 and 1943. In the course of some 400 pages she ranged widely throughout the bivalves describing and figuring in the most precise and beautifully illustrated detail the course of ciliary currents and the different types of cilia, with such matters as cuticular fusion and the nature of ctenidial musculature. These papers are an abiding source of knowledge, one to which I am glad to pay my testimony of gratitude and admiration. They put all workers on the bivalve Mollusca, now and in the future, in her debt.

Another source of interest, again initially stimulated by J. H. Orton, was in the Polyzoa. Early in her research career she published an account of their ciliary feeding mechanisms followed by a detailed systematic and anatomical account of the Loxosomatidea of the Plymouth area. Later she was to describe the structure and feeding mechanisms of cyphonautes larvæ. Her latest interest, made possible by the more extensive collecting range of the post-war research vessel, *Sarsia*, was in Brachiopoda with which her last seven papers, dealing with development of the lophophore, with feeding mechanisms and with systematics, are concerned.

Although of an extremely retiring disposition, Daphne Atkins was far from being devoid of personality. Within the field of her research interests she held most decided views, supported as they were by the results of years of the most careful observation. She has left a magnificant monument in her long series of published papers. As the Plymouth Laboratory made her work possible, this itself is a justification for the existence of that Laboratory.

C. M. YONGE

NEWS and VIEWS

The First American Manned Ballistic Rocket Flight

ON May 5, at 14.34 hr. U.T., a *Redstone* rocket was launched from Cape Canaveral in Florida, carrying Commander Alan Shepard, of the U.S. Navy, in a space capsule. This first United States attempt at manned ballistic rocket flight was entirely successful. The capsule was accelerated to a maximum speed of 5,100 miles per hour, reached a height of 115 miles and travelled 302 miles down-range over the Atlantic. As it re-entered the atmosphere the capsule's heat-shield was seen from the waiting ships to be glowing red. Commander Shepard seems to have suffered no ill-effects as a result of his 15-min. flight, during which he was subjected to a deceleration of 11 *g*. He was in radio communication with the ground throughout, and was able to climb out of the capsule before a helicopter arrived to pick him up. Though this rocket firing was only a first step towards orbital flight, Commander Shepard was able to test orbital techniques by controlling the orientation of the capsule under zero-gravity conditions.

New Carbon Isotope, Carbon-16

A NEW carbon isotope of mass 16 has been discovered by physicists of the Atomic Weapons Research Establishment, Aldermaston, working in collaboration with scientists of the Clarendon Laboratory, Oxford. A carbon-14 target was bombarded with a beam of 6-MeV. tritons (ions of tritium) from the Aldermaston Van de Graaff accelerator. In some cases, the force of the collision was observed to be sufficiently great to split the triton into its constituents of one proton and two neutrons and the two neutrons were captured by the carbon-14 to form a new isotope, carbon-16. By making precise measurements with a large magnetic spectrograph on the emitted protons, the mass of the new isotope was found to be 16·014702 atomic mass units. It was anticipated that carbon-16 would suffer beta-decay like carbon-14 and carbon-15, but with the difference that the product of the decay would still have sufficient energy to emit a neutron. This occurred, and use was made of this property to measure the half-life, which was found to be 0·74 sec. The most abundant isotope of carbon is, of course, carbon-12. Isotopes of mass 13, 14 and 15 are known, of carbon-14 and -15 are radioactive, and the former is the basis for the carbon-14 dating of archæological specimens.

Ministry of Aviation : Mr. W. O. Broughton

MR. W. O. BROUGHTON has been promoted to deputy chief scientific officer and appointed to the post of director of air navigation and reconnaissance research and development in succession to Mr. C. J. Carter, who has joined the defence research staff in Washington. Mr. Broughton started his career in the Civil Service in 1935 at the Royal Aircraft Establishment, where he was engaged on development work connected with automatic pilots, the *Queen Bee* pilotless target aircraft and stabilized automatic bombsights. In 1942 he transferred to Headquarters, Ministry of Aircraft Production, to take charge of a section concerned with the development of automatic pilots, gyroscopes and stabilizing equipment. He returned to the Royal Aircraft Establishment in 1947 as head of the Controls Division of the Instrument and Air Photography Department, remaining in this post until 1954, when he was transferred to Headquarters, Ministry of Supply. In 1955 he was appointed assistant director, being responsible for administration of research and development connected with automatic flight control systems, automatic blind landing, flight instrument systems and aircraft fire control systems. In addition to these systems, Mr. Broughton now assumes responsibility for research and development on air photography, bombsights, flight simulators and non-radio aircraft navigation systems.

Physics at Birmingham: Prof. W. F. Vinen

DR. W. F. VINEN, who has been appointed to a chair of physics in the University of Birmingham at the early age of thirty-one, was educated at Watford Grammar School and Clare College, Cambridge, where he was elected to a research fellowship in 1955. In 1958, he was appointed a University demonstrator in physics and a Fellow of Pembroke College. In close collaboration with his contemporary, Dr. H. E.

Hall, recently appointed to a chair at Manchester (see *Nature*, March 18, p. 877), Dr. Vinen conducted an elegant series of studies on the hydrodynamics of superfluid helium, with particular reference to the development of turbulence and the frictional effects arising from the interactions of the thermally excited 'normal fluid' with the vorticity of the ground-state, the 'superfluid'. The work of these two collaborators, which must ultimately be ranked as a classic investigation, soundly establishing quantum hydrodynamics on an experimental basis, culminated on Dr. Vinen's side with a direct demonstration of the quantization of circulation in the superfluid. This beautiful experiment may well be regarded as a worthy conclusion to the work of more than twenty years in Cambridge on the properties of superfluid helium, which began equally strikingly with the discovery of the fountain effect. In the organization of a new department and the development of new fields of research, Dr. Vinen will have full scope for the inventiveness and versatility which have been such a notable characteristic of his work up to the present.

Director of the National Fishery Institute, Ecuador: Mr. F. Bourgois

MR. FRANÇOIS BOURGOIS has been appointed director of the National Fisheries Institute, Guayaguil (Ecuador), for a period of four years. Mr. Bourgois has been Food and Agriculture Organization fishery officer in Haiti since last July. Prior to that, he was fishery officer and the Organization's representative in Tunisia for three and a half years. While in Tunisia, Mr. Bourgois was concerned with finding and charting new fishing grounds, improving the sardine fisheries and extending Tunisian trawling farther offshore. Together with one of the Organization's master fishermen, he introduced the use of underwater lamps into Tunisian sardine fishing. Mr. Bourgois joined the French Fisheries Service in 1945 as a fisheries expert and administrator. He was previously fisheries adviser to the Viet Nam Government, and fisheries expert with the Supreme Commander for the Allied Powers. His first assignment for the Food and Agriculture Organization was in 1956 in Libya. The Ecuadorian National Fishery Institute is the second major U.N. Special Fund fisheries project, with the Food and Agriculture Organization as executing agency, to be established in Latin America. The project calls for a Government contribution of 663,040 dollars over a four-year period, and a special fund contribution of 633,800 dollars. The purpose of the Ecuadorian Institute is to help the Government foster the country's economic development by a substantial expansion of fishing and ancillary activities. Facilities and maintenance for the Institute's two research vessels, and personnel are to be provided by the Ecuadorian Navy. The Navy will also provide hydrographic and meteorological information on areas not studied by the Institute's vessels and will provide a ship for several months of whale-marking each year in the seas of Ecuador.

Space Research in Britain

REPLYING to a question regarding Great Britain's contribution to a space research programme, Mr. D. Freeth, Parliamentary Secretary for Science, said in the House of Commons on May 2 that Great Britain's programme comprises five main elements. There is the programme of scientific experiments using sounding rockets. Further experiments will be made in satellites to be launched by the United States, with which Britain is also collaborating in testing communications using satellites. Thirdly, Britain is participating actively in the preparatory commission set up to plan a European organization for co-operation in scientific research in space. Great Britain and France have also proposed to other European Governments a co-operative programme for the development of satellite launchers beginning with one based on *Blue Streak* to be fired from Woomera. Finally, Britain is doing much analysis of satellite tracking data, including the operation of one of the three World Data Centres which act as international clearing houses for information on space research. Future plans in Britain will be considerably affected by the results of the discussions now taking place with other countries regarding the third and fourth elements in this programme. Mr. Freeth added that Britain is in very close touch with both the Australian and Canadian Governments, and he strongly disagreed with the suggestion that discouragement of British participation in a space programme is leading to an exodus of the finest brains of the country to the United States and Canada.

In a written answer on May 2, Miss Pile, Assistant Postmaster-General, said that the Post Office is co-operating in a wide-ranging communications satellite research programme which covers orbits, altitudes and frequencies, and the design of the electronic equipment in the communication satellites themselves. The first requirement is a ground station for joint experiments with the Americans in satellite communications across the Atlantic.

In reply to questions on May 4, the Prime Minister said that the Minister for Science, in his speech to the Geological Society on April 26, was re-affirming his acceptance of the view of the Advisory Council on Scientific Policy that a full-scale space programme on a purely national basis, including the development of a large launcher, would not be justified solely on scientific grounds. The wider problem of developing a launcher for heavy satellites is under discussion in Europe, and any further statement of policy must await the outcome of discussions. He hoped that Britain would be able to get the joint scheme, because of the enormous sums involved if the matter were to be pressed forward in all its aspects. In other questions reference was made to the expenditure of only £5 million on scientific research by the National Coal Board, and to the cost of the Russian rocket programme for launching heavy satellites as about equal to the cost of the whole defence programme of Britain. Mr. Macmillan emphasized that it is a matter of determining the right priorities and in this matter the Government looks to the Advisory Council on Scientific Policy for guidance,

Industry, Science and the Chemical Engineer

ON April 25, at the thirty-ninth annual general meeting of the Institution of Chemical Engineers, Mr. W. K. Hutchison, deputy chairman of the Gas Council, delivered the presidential address. He referred to the rapid growth in membership of the Institution. This occurred chiefly because of post-war expansion; chemical industry and chemical plant manufacturers all began to offer opportunities for employment to chemical engineers on a scale not contemplated before the War. The greatest demand is in the field of production, and, in particular, plant operation, where techniques of management are of special importance. The Institution is able to make one of its most useful contributions to the education of engineers by providing the teaching institutions with detailed information on the type of problems encountered by the professional engineer. In time, each chemical engineering course offered by various institutions would develop its own style and character and the employer would remain free to go to whichever seemed best able to produce the type of man he wanted. The final test of the engineer would always be success or failure in carrying out the work entrusted to him. The Institution could do no more than prepare him for such a test.

Mr. Hutchison referred to the concept of 'unit operations' which, for thirty years, has been retained as a basis for instruction in chemical engineering. Behind all unit operations there are fundamental physical or chemical concepts, so related that, if used with the necessary degree of mathematical skill, they might make unnecessary much of the existing content of chemical engineering instruction. Mr. Hutchison also mentioned an interesting situation in continental Western Europe, where only small groups are willing to call themselves chemical engineers or to recognize the coherent set of principles within which a profession can be practised. Many of the functions claimed by chemical engineering are fulfilled by combined teams of chemists, physicists and engineers.

The attraction of chemical engineering to many young men is its obvious connexion with the realities of industrial processes. The attitude is that of the engineer rather than of the scientist; the laboratory and the lecture theatre are tolerated only as stepping-stones to the world outside. If there is a latent conflict between the two aspects of engineering, "the engineer directing the great powers in nature for the use and convenience of man", and the scientist intent in his laboratory on advancing the frontiers of knowledge, the Institution does provide a solution. It is both a corporate body of practising engineers and a meeting ground for scientists. The primary aim of the Institution is the advancement of science —by which is meant all knowledge—through the skill of practising engineers and scientists alike.

The Cotton, Silk and Man-Made Fibres Research Association

In May 1960, the working party that had been set up to consider the possible fusion of the British Cotton Industry Research Association and the British Rayon Research Association recommended that the two Associations should be merged into one research association as from July 1, 1961. It has now been decided that this will be known as the Cotton, Silk and Man-Made Fibres Research Association, and its main responsibilities will be to serve the processing and merchant converting sections of the industries. The officers of the new Association will be as follows: *Director*, Dr. D. W. Hill; *Deputy Director*, L. A. Wiseman; *Assistant Directors*, G. W. Lobb (to be responsible for research administration), L. H. C. Tippett (to be responsible for physical and mechanical research), and Dr. A. R. Urquhart (to be responsible for chemistry and chemical processing). A large part of the research programmes and other work previously undertaken by the original Associations is being continued by the new organization. The main source of the Research Association's industrial income will be a research levy forming part of the levy collected by the Cotton Board. The Association will also receive a grant from the Department of Scientific and Industrial Research. Plans are already well advanced for the provision of a new chemistry and finishing building at the Shirley Institute, Didsbury, Manchester, which, it is hoped, will be completed by the end of 1962 or early 1963.

Science Museum Exhibition of a Fourteenth-Century Astronomical Clock

The Science Museum will be exhibiting during May 16–June 25 the first full astronomical clock to be produced in Britain for 250 years. The clock is an exact reproduction of one designed and constructed nearly 600 years ago by John Dondi, who was, at times, professor of logic, medicine and astronomy in Italy. During the years 1348–64, Dondi constructed his astronomical clock, which came to fame during the next two centuries, but afterwards it seems to have sunk into oblivion, and little was heard of it until the late G. H. Baillie, in the 1930's, translated the Latin manuscript which Dondi left behind giving a full description of just how he made the clock, with working drawings. The clock remained in Italy until 1585 and then went to Spain, where it was destroyed during the Peninsular Wars. Constructed within about fifty years of the invention of the mechanical clock, at a time when the standard clock was a clumsy forged-iron blacksmith's production, Dondi's clock presented an achievement of great refinement. Astronomical clocks showing the motions of the Sun, Moon and nodes began to be less rare in Europe during the late fifteenth and sixteenth centuries; but those embodying the motions of the five planets as well are rare at any period. The names of Immser and Baldewein came into prominence in Central Europe about 1550; in Western Europe little was done until Johann Klein of Prague and Aureliano and Cajetano of Vienna constructed their clocks in the last quarter of the eighteenth century. Later, clocks were built by Schwilgué in 1842 and Jensen in 1956, and in England there was only Samuel Watson in 1680 and Henry Bridges in 1730. It has fallen to Mr. H. Alan Lloyd to take up Baillie's work and complete it. After publishing a full précis of the translation in 1955, he decided to make a reconstruction of the clock. He was able to find collaborators in the managing director, Mr. Geoffrey Buggins, and in his co-director and chief craftsman, Mr. Peter Haward, of Thwaites and Reed, Ltd. Following the exhibition in London, the clock will be taken to the Smithsonian Institution, Washington.

X-ray Protection at High Voltages

The National Committee on Radiation Protection and Measurement of the U.S. National Bureau of Standards has issued a new handbook with information about how to obtain medical protection from X-rays up to 3×10^6 V. (National Committee on Radiation Protection and Measurements. Report No. 26. Pp. viii+52. (Washington, D.C., Government Printing Office, 1961.) 25 cents.) The handbook sets out standards of safety and contains data and recommendations relating to all persons involved, including the manufacturers of the apparatus and designers and builders of the rooms in which it is housed. Basic requirements for safety standards are essentially the same in this handbook as in its immediate predecessor (No. 60). Tables have been revised to conform with the new lower maximum permissible dose adopted by the Committee in 1957, and the differences in the maximum permissible doses allowed in controlled areas and their environs. Recommendations have been changed to cover situations created by recent technical advances in machine design, and by the development of new radiological techniques. The underlying philosophy, however, remains as it was originally expressed by the Committee thirty years ago, namely, that unnecessary radiation exposure should always be avoided and all exposure kept to the minimum compatible with practical clinical requirements.

Field Studies in Scotland

DESPITE the attractiveness of the Study Centre at Garth, the Scottish Field Studies Association may have to discontinue its activities for lack of support. In contrast to the encouraging number of students who are attending Field Study Centres in England, the number of student days spent at Garth fell from 2,972 in 1959 to 2,539 in 1960. Of the 29 courses offered, 7 had to be cancelled for lack of support. The Association is appealing not only for financial help but also for increased support from Scottish and other local education authorities. In her foreword to the annual report, Dr. Margaret Stewart writes that "there is plenty of lip service to the importance of Field Studies in education curricula, but so long as it is left to the initiative of individual teachers the work of the Association cannot be developed on a firm and lasting basis" (Annual Report, 1960. The Importance of Field Studies in Modern Education. By Paul F. Holmes. Garth House as a Centre for Ecological Botany. By Fred N. and Brenda D. Haynes. Pp. 27+4 plates. (Glasgow: Scottish Field Studies Association, 1961.) 2*s.* 6*d.*). Information about the Association can be obtained from 179 West Regent Street, Glasgow 2.

Organization of Sandwich Courses

THE National Advisory Council on Education for Industry and Commerce has started an inquiry on the organization of sandwich courses in technical colleges and other colleges of further education. A sub-committee under the chairmanship of Mr. E. L. Russell, chief education officer for Birmingham, has been set up "to examine the organization of sandwich courses with a view to using college staff, equipment and accommodation and industrial training facilities to the best advantage; and in particular to consider 'end-on' arrangements". The sub-committee is examining the various ways in which practical experience in industry is combined with academic study in technical college courses. These methods include the 'end-on' system by which two quite separate groups of students follow the same course, but use the college alternately, one group being in college while the other is in industry. Any organization or persons wishing to submit evidence to the sub-committee is asked to write to the Secretary, National Advisory Council on Education for Industry and Commerce, Ministry of Education, Curzon Street, London, W.1.

Zoological Society of London

DURING 1960 the Zoological Society of London was the recipient of three munificent bequests which will enable it to extend considerably its activities. The Trustees of the Nuffield Foundation granted the Society £100,000 to found an Institute of Comparative Medicine. Mr. Jack Cotton is providing £250,000 to help the rebuilding programme, and the Ford Foundation gave 550,000 dollars (nearly £200,000) to endow research fellowships in animal breeding. A major part of the new research activities will lie in the field of comparative medicine. The Institute of Comparative Medicine is to be associated with the name of Lord Nuffield. The grant is also intended to allow for the creation of two research fellowships in comparative medicine. The Ford grant makes it possible to undertake a systematic study of the reproductive habits and physiology of those animals in the Society's collections which breed readily in captivity. These studies will be supervised by a committee of well-known scientists distinguished for their contributions to knowledge of reproductive physiology. On the basis of the advice of this committee, the Council has already appointed the first three research Fellows. The Society is now planning new laboratories for their accommodation. Mr. Cotton's gift is the key which sets in motion the plan for reconstruction of the Regent's Park Gardens as devised by Sir Hugh Casson and Mr. Peter Shepheard in consultation with the Society's resident architect, Mr. F. A. Stengelhofen. Details of the bequests and other information about the many forward-looking activities of the Society are set out in its annual report for 1960 (Pp. 54+8 plates. London: Zoological Society of London, 1961). H.R.H. the Duke of Edinburgh has accepted the presidency in succession to Sir Landsborough Thomson.

The Ciba Foundation

THE report for 1960 of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research, which includes, as usual, details of symposia and their participants, of the study groups and research meetings, and lists of publications held and issued, records that the Foundation provided accommodation during the year for 825 scientists from 37 countries (Pp. 63. London : Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research, 1961). Five three-day international conferences were held and membership of these symposia is now limited to about 30. Besides four one-day study groups, the Foundation arranged five evening discussion meetings, five research meetings, a guest symposium on "Aspects of Ciné-Indoscopy and Ciné-Radiology", seven sessions of scientific films, and a new series of dinner meetings known as the Dunant Coterie. Three such meetings were held in 1960 and the twelfth Ciba Foundation Lecture was delivered by Prof. J. Konorski, the fourth annual lecture on ageing by Dr. P. J. Thung, and the Louis Rapkine Lecture by Medicin-Lieutenant M. Flauder. Seven Anglo-French bursaries were awarded by the British selection committee for medical graduates to visit France, and two by the French selection committee for visits to London Medical Schools. Three volumes of the proceedings of symposia, one of a colloquium on endocrinology and two of study groups were published during the year.

Photon Rocket

OPTICAL and mechanical phenomena to be encountered by a space traveller moving with a velocity approaching that of light are discussed by S. M. Rytov (*Priroda*, 4, 64 ; 1960). The greatest danger to such a traveller will be encounters with relativistic cosmic dust and wind. A collision of the space ship with a cosmic particle one milligram in weight will spell complete destruction. In spite of such a warning G. G. Zelkin describes the construction of a purely hypothetical photon rocket (*Priroda*, 11, 69; 1960), many kilometres in length and propelled by fuel, the energy of which is wholly transformed into luminous energy.

A New Elementary Particle

IN a brief note Din Da-Tzao and E. N. Kladnitzkaya (*Priroda*, 8, 17; 1960) give an account of the discovery in the Dubno laboratory of a new elementary particle—an antisigma minus hyperon. This discovery was made by a group of research workers under the leadership of V. I. Weksler and Van Gan-Chan. As shown by the particle track photograph this particle was produced through the collision of a pi-meson with the nucleus of a carbon atom.

French Scientific and Technical Books 1950–60

A COLLECTED catalogue of French scientific and technical books 1950–60, with an introduction by P. Piganiol, comprises a selection of books at present on sale and published between 1950 and 1960 (*Catalogue Collectif des livres Français de Sciences et Techniques*, 1950–1960. Pp. viii+242. Paris: Cercle de la Librairie, 1961). The books are classified by subject in five main sections under science, and eleven under technology, and alphabetically by title within the sub-sections. There are alphabetical subject and author indexes.

The Society for General Microbiology

THE Society for General Microbiology held its annual general meeting on April 10, at the Royal Institution. For the forthcoming year the following officers were elected: *President*, Prof. R. Lovell; *Treasurer*, Prof. K. E. Cooper; *Editors*, Prof. B. C. J. G. Knight and Mr. A. F. B. Standfast; *Meetings Secretary*, Dr. B. W. Lacey; *General Secretary*, Dr. S. T. Cowan. The Marjory Stephenson Memorial Lecture, "The Development of Microbiology", was given by Prof. B. C. J. G. Knight, and a symposium on the Microbial Reaction to Environment was held on April 11 and 12. The subject of the Society's symposium in 1962 will be "Microbial Classification".

Electron Microscopy

THE Electron Microscopy Group of the Institute of Physics and the Physical Society is holding its annual conference at the University of Nottingham during July 10–14. The conference will be concerned mainly with the physics of the electron microscope and its applications. Among the main topics to be discussed are: "Electron Microscopes and Electron Optics"; "Electron Microscopy of Thin Films"; "The Theory and Scope of Electron Diffraction Methods"; "Miscellaneous Techniques and Applications of Electron Microscopy". The conference will also include a symposium on "The Physics of Sectioning and the Embedding Process". Further information can be obtained from the Administration Assistant, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

Seminars on Nuclear Science

THE European Nuclear Energy Agency of the Organization for European Economic Co-operation has arranged with the Atomic Energy Research Establishment at Harwell and the Centre d'Etudes Nucléaires at Saclay for two international seminars on nuclear energy. Designed for the teaching staffs of universities and higher technical colleges, each seminar will accept about fifty applicants, who will have the opportunity to study the latest advances in nuclear science and techniques, to do certain practical work, and to visit nuclear installations. The Harwell seminar will take place during July 10–21, and that at Saclay, June 26–July 7. The costs of both seminars are being borne by the European Nuclear Energy Agency, and participants will only be required to pay travelling and living expenses. Further information can be obtained from the Organization for European Economic Co-operation, European Nuclear Energy Agency, 38 Boulevard Suchet, Paris 16*e*.

Announcements

PROF. K. E. BULLEN, professor of applied mathematics in the University of Sydney, has been awarded the William Bowie Medal for Unselfish Co-operation in Research by the American Geophysical Union, in recognition of his contributions to knowledge of the interior of the Earth.

DR. K. J. IRVINE is to succeed Mr. W. E. Bardgett, at present research manager for research and development of the United Steel Companies, Ltd., when the latter retires on July 1. Dr. Irvine will take the title of metallurgical research manager.

THE Institute of Fuel is organizing a second conference on "Waste Heat Recovery", which will be held in Bournemouth during May 15–19. Further information can be obtained from the Institute of Fuel, 18 Devonshire Street, Portland Place, London, W.1.

THE theme of the 1961 convention of the British Institute of Radio Engineers is to be "Radio Techniques and Space Research". The Convention is being held in the University of Oxford during July 5–8. Further information can be obtained from the General Secretary, British Institution of Radio Engineers, 9 Bedford Square, London, W.C.1.

THE Royal Meteorological Society is holding a two-day meeting at the University of Exeter during July 12–14. The meeting will include symposia on "Winds and Circulation in the Upper Atmosphere" and "Medium-scale Diffusion in the Atmosphere". Further information can be obtained from the Assistant Secretary, Royal Meteorological Society, 49 Cromwell Road, London, S.W.7.

THE fifth international conference on "Ionization Phenomena in Gases", sponsored by the Association of the German Physical Societies (Plasma and Discharge Physics Group), will be held at Munich during August 28–September 1. Further information can be obtained from Prof. K. H. Höcker, Technische Hochschule Stuttgart, Herdweg 51, Stuttgart.

THE 1961 biennial conference of the Oil and Colour Chemists' Association is to be held at Torquay during May 30–June 3. The general title of the conference will be "Physics in Surface Coatings". Further information can be obtained from the General Secretary, Oil and Colour Chemists' Association, Wax Chandlers' Hall, Gresham Street, London, E.C.2.

ERRATA. IN the note entitled "The Geological Society of London", appearing on p. 492 of May 6 issue of *Nature*, the final sentence refers to newly elected members of the Society's Council. Furthermore, Dr. P. A. Sabine, one of the newly elected secretaries, is the chief petrographer, H.M. Geological Survey.

THE SCALE OF THE SOLAR SYSTEM

By THE STAFF, MILLSTONE RADAR OBSERVATORY, LINCOLN LABORATORY*,
MASSACHUSETTS INSTITUTE OF TECHNOLOGY,
WESTFORD, MASSACHUSETTS

THE close approach of Venus during April 1961 has permitted a re-determination of the scale of the solar system by means of radar distance measurements of this planet. Previously, measurements of this kind have been made by Price *et al.*[1] and Evans and Taylor[2]. These earlier experiments led to a value for the solar parallax of $\pi = 8{\cdot}8022 \pm 0{\cdot}0001$ sec. of arc. This is not in agreement with new measurements made using the Millstone Radar Observatory of the Massachusetts Institute of Technology, Lincoln Laboratory, located at Westford, Massachusetts, in March and April 1961.

In all the experiments the transmitter is operated for a period somewhat longer than the two-way travel time. Following the transmission interval (usually about 5 min.) the received energy is integrated at different range-intervals for a duration corresponding to the echo time. In this way most possible sources of spurious echoes are removed. Allowance is made in the summation process for the gradual drifting of range with time. A display of the results of thirty such 'runs' for April 8 is shown in Fig. 1. Included in the processing is a calibration pulse, chosen to approximate the expected intensity of the Venus echo. The Venus echo may be seen to rise some 23 standard deviations above the mean noise-level. The echo intensity corresponds to a received power-level of 163 db. below 1 mW.

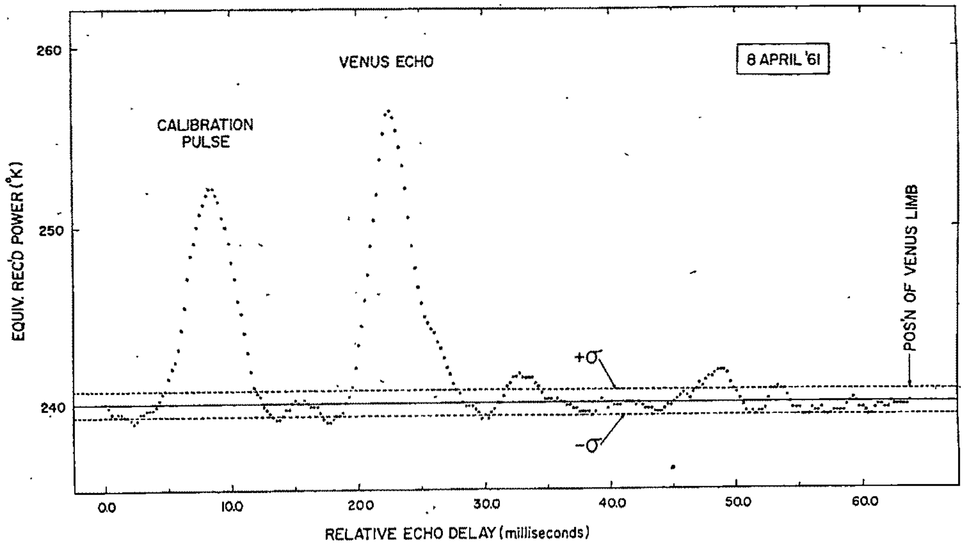

Fig. 1

This equipment operates with the following parameters: frequency, 440 Mc./s.; aerial gain, 37·5 db.; peak transmitter power, 2·5 MW.; receiver noise temperature, 240° K.; transmitter pulse-lengths, 0·5, 2, or 4 msec. The transmitter interpulse period has been varied at approximately daily intervals during the course of experiments which began on March 6. In this way the uncertainty in the total number of interpulse periods in the time for the pulse to travel the two-way distance to and from Venus can be removed. The value for the range of the planet has been converted to a value for the solar parallax by using an ephemeris computed in a manner described by Pettengill and Price[3]. The preliminary value obtained from twenty independent experiments conducted during the period March 6–April 12 is:

$$\pi = 8{\cdot}79450 \pm 0{\cdot}00008 \text{ sec. of arc}$$

which corresponds to a mean solar distance of 149,597,700 ± 1,500 km. The observations are being continued and it is expected that a final analysis of all the measurements will yield a value substantially more accurate than the new value reported here.

From the intensity of the echo we conclude that Venus scatters about 12 per cent of the incident energy. This is not greatly different from the amount scattered by the Moon (7 per cent, ref. 4) and suggests that Venus has a solid surface.

A frequency analysis of the returned signal power discloses very little spectral broadening. Two 4-min. runs analysed to date show that essentially all the returned power is contained within a band-width of less than one cycle per sec. Until some measure of the angular scattering law is obtained it is impossible to determine the planetary rotation. It is interesting, to note, however, that if one assumes an angular distribution similar to the Moon, an apparent rotational period consistent with the synodic period (584 days) is obtained.

---

FUNGICIDES IN AGRICULTURE AND HORTICULTURE

FROM time to time estimates are published of the enormous annual loss of crops throughout the world due to pests and diseases. A considerable proportion of these losses, equal to the produce of millions of acres of agricultural land, arises from fungal diseases, and in most cases the use of fungicides provides the most effective remedy. In recent years there has been good progress in the development of new fungicides; crop losses are still great, however, even in Britain, where potato blight, for example, still destroys thousands of tons of potatoes each year. Meetings concerned with research on fungicides do not occur frequently in Britain and considerable importance was therefore attached to the symposium entitled "Fungicides in Agriculture and Horticulture" organized by the Pesticides Group of the Society of Chemical Industry and held in London during March 20–21.

The programme was well balanced to include treatment of fundamental as well as practical aspects of the subject. The three papers delivered on the first morning under the general heading of "Current Usage and Recent Developments" and dealing with fruit, glasshouse crops and agriculture respectively were mainly practical. It is well known that organic fungicides have been used increasingly in crop protection in recent years, but it was interesting to hear from these three speakers that inorganic materials such as elemental sulphur, lime-sulphur and Bordeaux mixture still hold a very important position.

Dr. A. H. M. Kirby dealt briefly with soft and stone fruits and more fully with pome fruits. Scab has been the disease requiring most attention on apple and pear, but of all the chemicals used for its control none is without some defect. For example, captan, which gives excellent control, allows mildew to increase—this, incidentally, is now the most important disease for which a safe, cheap and adequate control is still required. The dangers of phytotoxicity and mammalian toxicity with some of the materials in current use were emphasized, and a particular point made was that the harmonizing of biological and chemical control of pests and diseases is worthy of greater attention in spray programmes.

In glasshouse crops, as W. H. Read pointed out, a system of monoculture is usually practised and the methods and costs of partial soil-sterilization to combat the soil-borne diseases encouraged by this system were given. The disadvantage with chemical soil sterilants is the long period required for the chemical or its breakdown products to disappear from the soil.

Since most glasshouse crops are susceptible to phytotoxicity and mechanical damage, there is usually no definite spray programme in glasshouses, the policy being to wait until disease needs to be controlled. The uses of sprays, aerosols, smokes and vaporization were discussed as methods of dispersing the chemicals employed to control a number of important diseases of glasshouse crops.

Unlike the previous speakers, Dr. F. C. Gayner was not restricted to considering the use of fungicides in Britain. Under the title "Fungicide Usage in World Agriculture" he gave the amount and value of sulphur, copper, mercury and organic fungicides used throughout the world during 1958. Although 12,000 tons of organic fungicides and 300 tons of mercury were used in that year, 275,000 tons of sulphur, used mostly as a dust, and 56,000 tons of copper were sold, the latter mainly as copper sulphate for the manufacture of Bordeaux mixture. Most of this interesting paper was concerned with the use of fungicides to control the eight major diseases on crops of world importance.

The second session of the symposium comprised three fundamental papers on "Theoretical Bases for Fungicides". The first of these, prepared by Dr. A. H. McIntosh, was read by Dr. C. Potter; but in the absence of the author it was inevitable that the discussion suffered some limitations. The results were given for the fungistatic action of nineteen chemicals, some of them well-known fungicides, against *Botrytis fabae* at temperatures between 10° and 25° C. and at intervals of up to 14 days. In general, an increase in temperature was shown to increase the toxicity and speed of action, whereas the apparent toxicity at any one temperature decreased as time passed. It emerged that there is little evidence for the generally held belief that spores are more resistant to fungicides at their optimum temperature for germination and also that the results may be misleading if spore germination tests are assessed before the ED_{50} has been allowed time to reach a steady value. An important point was made here concerning the loss of fungicides by sorption on the glassware used in spore-germination tests. This is particularly true of heavy-metal salts and, in one case cited, using mercuric chloride, some 70 per cent of the original amount was lost from solution in 24 hr.

Physical measurements and biological behaviour also formed an integral part of the succeeding paper by Dr. M. J. Janssen of Utrecht. Work on fungicides in the Netherlands has long been in the forefront of world research, and in recent years a series of papers dealing with the dithiocarbamate fungicides has been published by the team led by Prof. G. J. M. van der Kerk. Dr. Janssen's contribution was concerned with the mode of action of the dithiocarbamates, and he divided the work on this subject into three phases, dealing mainly with the most recent work relating to metal complex formation. He showed that the dithiocarbamates act in much the same way as 8-hydroxyquinoline, for which the importance of metal chelation has been demonstrated by Albert. A quantitative agreement exists between toxicity and concentration of the dithiocarbamate ion itself and its complexes with copper. Thus the different growth pattern in several fungi can be ascribed to their sensitivity not only to the dithiocarbamate ion in the medium but also to the complexes in which one or two dithiocarbamate ions are attached to the bivalent copper ion. Reference was also made in this paper to the current fashion of postulating metal-binding as responsible for the observed phenomena in other biological systems. In the discussion, there was general support for Dr. Janssen's opinion that the theory that chelation is of basic importance in relation to the activity of plant growth-regulating substances is unwarranted.

Dr. E. Somers pointed out that in terms of weight of chemical removed from solution by fungal spores, the fungicides in current use possess low toxicity compared with animal poisons, insecticides or even bactericides. He felt that the common method of determining uptake of fungicide by measuring the amount remaining in solution after fungal spores have been removed from it gives little information on the actual amount which has penetrated the spores. Using captan and a series of ring-substituted derivatives no correlation could be established between lipid solubility on one hand, and uptake or fungitoxicity, in terms of the ED_{50}, on the other. It was shown that thiol-groups within the cell are concerned in the action of captan ; furthermore, the chemical appears to be taken up only by living cells. This is quite different from the results obtained with radioactive copper, the uptake of which was found to be non-specific. Thus, any part of the fungal cell, whether living or dead, will apparently remove copper-64 from solution ; that which accumulates on the outside of the cell therefore probably plays no part in the fungicidal activity of this metal.

The first paper on the second day of the symposium, given by Prof. G. J. M. van der Kerk of Utrecht, was concerned with new developments in organic fungicides. An authority in this field, Prof. van der Kerk first described how fungicide research in Holland is co-ordinated between several institutions. He then went on to forecast that another general group of organic fungicides superior to the dithiocarbamates on grounds of activity, simplicity of molecular structure and cost is unlikely to be found. He considered it more likely that in the future specific materials will be developed to control specific diseases.

In the field of protectant fungicides, the organo-tin compounds have recently been introduced commercially as a result of research which started in 1950. Triphenyltin acetate is already marketed by Germany for use on a wide range of crops, but its phytotoxicity and mammalian toxicity require special attention. The triphenyltin sulphides, on the other hand, are much less toxic towards higher plants and animals but their antifungal spectra also show more specificity.

In the search for systemic fungicides progress has been made along three main lines: by using chemicals which are translocated within the plant and are themselves fungitoxic; by using chemicals which are broken down by the plant or the pathogen to form systemically distributed fungicides; and by using compounds which are neither fungicidal *per se* nor give rise to fungicidal degradation products but interfere with the host's metabolism and render it resistant to attack. Prof. van der Kerk reported on the progress being made in Holland along all three of these lines. Procaine (diethylaminoethylester of *para*-aminobenzoic acid) shows promise as a systemic fungicide *per se*, but none of its derivatives is of interest and it may be significant that procaine has so far been shown to be active only against powdery mildew on cucumber. This disease again showed itself to be useful for the demonstration of systemic fungicidal activity with sodium dimethyldithiocarbamate. This compound, which is an active plant-growth regulator, is degraded within the bean plant and, by means of an elegant bioassay technique involving *Glomerella cingulata*, can be shown chromatographically to form at least three antifungal derivatives. Resistance to *Cladosporium cucumerinum* has been increased by providing cucumber plants with enantiomorphs of naturally occurring amino-acids; likewise, thiourea and phenylthiourea, which are inactive *in vitro*, have been found to confer resistance against certain diseases when provided to plants through their roots.

The activity of fungicides in relation to their chemical structure was considered by several speakers in relation to the particular compounds with which they were interested. Dr. D. Woodcock, in his contribution, dealt specifically with structure-activity correlationships of some nitrogenous antifungal chemicals. The importance of physical properties such as lipophilic character was discussed in relation to mode of action. Chelation was also considered, in particular with regard to its influence on the fungitoxicity of oxine (8-hydroxyquinoline) and related compounds. Other compounds dealt with by Dr. Woodcock included imidazolines, guanidines and triazines.

Prof. R. L. Wain and his colleagues at Wye College have been closely associated with research on systemic fungicides for some years and Prof. Wain gave an account of the progress made in this field. He directed attention to the important fact that most plants possess a wide degree of resistance to fungal attack, and pointed out that in some cases this resistance may depend on the possession by the plant of anti-fungal chemicals within its tissues. The observation that the tissues of *Vicia faba* were fungitoxic provided an opportunity of investigating this system from the point of view of "natural systemic fungicides". The isolation of the anti-fungal compounds present in *Vicia faba* has, in fact, been in progress at Wye for some time. Early in these investigations it had to be shown that the observed effect was due to the presence of fungitoxic chemicals and that the broad bean was the most suitable subject for the investigation. Details of the biological work leading to chemical extraction of the fungal inhibitors and the techniques developed for dealing with large numbers of fractions obtained from the extracts were given by Dr. D. M. Spencer. Dr. C. H. Fawcett then described the successful extraction of the most potent two chemicals : one a keto-yne and the other a sulphur-containing acid with certain properties similar to those of a nucleotide. While somewhat unstable, there is no doubt that these materials are highly fungitoxic and their presence in *Vicia faba* may well prove to be of considerable significance.

The last two contributions dealt with two new fungicides now in use. D. J. Higgons described the research which led to the field trials and ultimate commercial application of 2,6-dichloro-4-nitroaniline, particularly against *Botrytis cinerea* on lettuce, and Dr. W. F. Jepson dealt with the orchard use against scab diseases and the possible mode of action of *n*-dodecylguanidine acetate.

The contributions to this symposium ranged widely within the field of fungicides. The practical aspects of their use were discussed, theories on mode of action were described, research being carried out towards the development of new fungicides was reported and details were given of two new materials now on the market. Perhaps part of its undoubted success can be ascribed to the comparative rarity of meetings such as this and it is to be hoped that others will follow at suitable intervals. The organizers of the symposium are to be congratulated on their choice of subject, and the participants—indeed all those interested in fungicides—look forward to the early publication of the monograph containing the contributions and discussions. D. M. SPENCER

THE NATIONAL PARKS COMMISSION

THE eleventh annual report of the National Parks Commission*, which covers the year ended September 30, 1960, again records disappointment at the non-introduction in Parliament of any Bill to give effect to the amendments to the Act which the Park Planning Authorities and the Commission recommended to the Minister. This was in spite of the fact that at a Conference of Park Planning Authorities at Windermere in May, the Permanent Secretary to the Minister stressed the importance of having suggestions ready in case they were wanted at short notice. Within the limits of its powers, the Commission records a year of quiet progress, particularly in the designation of areas of outstanding natural beauty, for which the Minister has now confirmed 12 orders covering 1,700 square miles, and several local planning authorities have taken advantage of the special powers provided by the Act for actions aimed at preserving and enhancing the natural beauty of these areas. After informal discussions with the chief bodies concerned the Commission is now considering what advice to give to the Government regarding the Broads in the light of the recommendations of the Bowes Committee of inquiry into inland waterways.

Much of the report consists of notes on progress and activities in the individual Parks, which it is impossible to summarize here, but with the excellent illustrations which continue to characterize the report, the Commission's annual report is itself a first-class piece of publicity, and one encouraging general note struck in the report is that it has at last been able to expand such activities and to appoint a small additional staff for the purpose. A conference of park authorities on the subject was arranged in July 1960, at which one topic discussed was the provision of information centres in all the National Parks. This has been limited hitherto primarily by finance which the 1949 Act failed to provide. The Commission regards such information centres as of the utmost importance and has proposed to the Ministry of Housing and Local Government an increased appropriation for the purpose.

A disappointing feature of the Commission's work stressed in the report is the lack of progress with long-distance routes. Although all but one of seven proposals for such routes submitted to the Minister have been approved, after ten years work not a single route has yet been completed on the ground, and there are still major difficulties in regard to the earliest and longest—the Pennine Way. Apart from this, development questions figure largely in the preoccupations of the Commission, the question of electricity distribution lines underground being again prominent. Strong exception is taken to the attitude of the South Wales Electricity Board to a request by the Pembrokeshire County Council for a small amount of underground cable in the vicinity of Whitesands Bay, St. David's, as quite at variance with the assurances given by Lord Mills when Minister of Power in a debate on the Electricity Bill, 1957. Moreover, in spite of further assurances given on the amenity clause in the Act in a debate in the House of Lords, in February, the Commission, while noting the Government's claim in the debate that all officers of the Electricity Boards are fully alive to the provisions of Section 37 of the Act, suggests that their appreciation of its implications could sometimes be improved.

Like difficulties have arisen in electricity supply to Borrowdale and to Martindale, and while regretting the existence of the Ballistic Missile Early Warning Station at Fylingdales in the North York Moors National Park, the Commission records its thanks to the Air Ministry for collaboration in an attempt to minimize the impact on the scenery. Protests was also made against the proposal, now abandoned, to rebuild Princetown Prison in the Dartmoor National Park and the Peak Park Planning Board was supported in its opposition to the proposal of the Sheffield Corporation to construct a refuse tip at Ringinglow, a proposal finally rejected by the Minister on appeal. Much anxiety is also expressed about the multiplicity of proposals for the erection of aerial masts on prominent sites, and despite the existence of Government arrangements, under which all proposals for new masts must be cleared centrally, and anyone proposing a separate site must show strong reasons for not conforming, the Commission continues to watch the position with some concern, although permission to erect a police mast of 150 ft. on Foel Eryr in Mynydd Preseli has recently been refused by the Minister.

THE WORLD HEALTH ORGANIZATION

THE outstanding activity of the World Health Organization in 1960 was the assistance given to enable the Republic of the Congo (Leopoldville) to meet the emergency health situation in which it found itself immediately after attaining independence. This is described in the annual report of the Director-General for 1960*.

Acting on a request from the Secretary-General of the United Nations for assistance with the rapidly deteriorating health conditions in the Congo, the Organization accepted the responsibility of co-ordinating, through the Ministry of Health, the activities of all international personnel concerned with the health of the civilian population. The report outlines the action taken by the World Health Organization during July, August and September, with the assistance of medical teams provided by national Red Cross societies and certain Governments.

The programme for the eradication of malaria from the world is reported as having made significant progress in various fields, although handicapped by a persistent shortage of funds. Sixty-one countries

* Official Records of the World Health Organization, No. 105: the Work of WHO, 1960—Annual Report of the Director-General to the World Health Assembly and to the United Nations. Pp. x+224. (Geneva: World Health Organization; London: H.M.S.O., 1961.) 6 Swiss francs; 10s.; 2 dollars.

are now fully engaged in this programme; in another nineteen, planning has reached an advanced stage, and, in seventeen other areas—mainly in Africa—the Organization is assisting with preliminary work. Some idea of the complexity and scope of these campaigns is conveyed by the variety of the Organization's work on malaria as reflected in this report—a wide range of research, assistance with training, planning and organizing campaigns and, as the programmes advance, with evaluating and assessing their efficacy and results.

The World Health Organization's assistance to Governments for the control of yaws, smallpox and tuberculosis, leprosy and various diseases increased significantly during the year. Medical research was intensified on practically all communicable diseases, the main co-ordinated effort being centred on virus diseases and on bilharziasis.

The year 1960 was the first year of full implementation of the intensified programme of medical research. Although the programme is concerned mostly with communicable diseases, work has begun on cancer, cardiovascular diseases, radiation medicine and human genetics. It is made clear in the report that the Organization's role is primarily to provide services to research and to co-ordinate the work being done in national centres. "It is, I believe", writes the Director-General in his introduction, "a gratifying fact that much of the medical research supported by WHO has grown out of the Organization's current field programme and is being carried out by national institutes and national staffs".

For the World Health Organization, as for the United Nations, the emergence of new independent States brought a marked increase in membership. In planning for the future, account has been taken of the particular needs of these newer countries, so as to ensure the most effective use of their often limited resources in the progressive development of balanced health programmes.

In most countries essential health work is being handicapped by shortage of trained professional and auxiliary personnel, and much of the Organization's work is concerned with education and training in one form or another. Under the Organization's fellowships programme, more than 1,000 fellowships were provided in the period covered by the report. In addition to details of the fellowships awarded for both group training and individual studies, the report gives information on the other aspects of the World Health Organization's work to further the training of professional and auxiliary health workers: courses, study tours, seminars and a variety of other meetings were organized, and experts were provided to serve as visiting teachers or as members of demonstrations and training teams. For example, in the first nine months of 1960, the Organization sent more than 160 nurses to help with nursing and midwifery training in forty-five countries.

In the field of environmental sanitation, emphasis was laid on the training of sanitary engineers and sanitarians, and on providing safe water-supply and waste disposal. In certain regions—Europe, for example—work was concentrated on river, lake and sea pollution and other problems resulting from the rapid growth of cities, such as air pollution. The growing use of atomic energy in power production, and of ionizing radiation in industry and medicine has given rise to several problems, and many Governments are becoming increasingly aware of their responsibilities in radiation health. The Organization's programme is orientated mainly towards assisting health authorities to strengthen their competence in radiation questions in order to meet these responsibilities.

MEASURING INDIGESTION

INVESTIGATORS in the food research group and analytical chemistry laboratories of the Stanford Research Institute have developed a method to measure the degree of digestibility of any food for a particular individual. Basically, one reason for the discomfort caused by certain foods is related to the bacteria flora that inhabit the intestines of all mammals. When a person eats a food he can digest only partially it is attacked, when it reaches the lower part of the small intestine, by organisms which digest the remaining material. These bacteria form hydrogen gas as a by-product in the process, and resulting discomfort depends on the amount of gas; this, in turn, depends on the constitution of the flora of that individual and the quantity of undigested food.

The project team reasoned that if gas pressure is present, the hydrogen should pass through the semi-permeable intestine wall into the blood stream. Because hydrogen is inert and therefore unchanged by body chemistry, the gas should eventually pass into the lungs and be expelled in the breath. They modified a gas chromatograph so that, if a bag is blown up by the subject, the hydrogen in the breath can be measured. By making the test after feedings of separate foods, they could determine what foods and how much are causing indigestion.

Some aspects of the investigation were sponsored by the U.S. Department of Agriculture and the Idaho Bean Commission. A unique application of the method was utilized by the latter organization and is outlined in a recent issue of *Research* (13, No. 1; January–February 1961). Beans in many individuals produce hydrogen and methane, which also are detectable by chromatography. A chemical and leaching process was developed by the food research group to make beans more generally digestible and greatly reduce gas formation, while not altering their taste. The breath-analysis technique was a useful tool in proving the bean treatment.

The individual digestive idiosyncrasies of animals, which cannot announce the fact that they have 'heartburn', may be detected by the chromatograph method. Various medical applications have also been suggested. For example, because intestinal bacteria populations increase rapidly by feeding on foods undigested in the stomach, the chances for future digestion problems are increased. With individual analysis, it may become possible to control the number of undesirable bacteria through selection of easily digested foods which will 'starve them out'.

A RADIO WAVE MECHANISM TO ACCOUNT FOR THE KNOWN DISTRIBUTION OF VAN ALLEN BELTS ABOUT THE EARTH

By JOSEPH M. BOYER

Northrop Corporation, Beverly Hills, California

A NUMBER of recent theories[1,2] related to the entrapment of charged particles in the Van Allen belts about the Earth appeal solely to the magnetostatic field of the Earth or Sun for the 'bottle' or trap mechanism. It may be of some value, conversely, to ascertain if the Van Allen belt phenomenon can be predicted in some detail by a simple theory which deliberately omits any recourse to the magnetostatic flux of the Sun or Earth as a charge-trapping means.

Due to the work of Mie[3] and Debye[4] it may be shown that upon the closed surface of a spherical body of matter a system of resonant modes of current will be established by illumination of the body by incident electromagnetic waves vibrating at frequencies within a certain portion of the spectrum called the 'critical band'. Excitation of such resonant surface current modes on the spherical body will, in turn, produce maxima in the scattered electromagnetic fields in the spherical directions φ, θ, of the space surrounding the body; such field distributions will differ from those established by the same body when illuminated by waves having vibrational frequencies lying outside the 'critical band' spectrum region. Here, the electrical constant of the matter comprising the spherical body is denoted k_1, and the electrical constant k_2 of the immersion medium about the body is first assumed to be that of a vacuum. We have: $k_1e = e_1/e_0$; $k_1\mu = \mu_1/\mu_0$; $k_2e = e_0 = 8{\cdot}854 \times 10^{-12}$ farads/metre (M.K.S.) ; $k_2\mu = \mu_0 = 1{\cdot}257 \times 10^{-6}$ henries/metre (M.K.S.) ; and k_1/k_2 is other than unity in terms of the critical band frequency spectrum considered.

Now, let the medium k_2 contain a continuous spectrum of electromagnetic energy emitted by a source so distant that wave-fronts are essentially plane in the vicinity of the sphere. By the spherical vector wave-functions, the resultant electromagnetic field will be:

$$\overline{E} = -\sum_n (a_n\overline{M}_n + b_n\overline{N}_n), \quad \overline{H} = -\sum_n \frac{k}{i\omega\mu}(a_n\overline{N}_n\overline{M}_n) \quad (1)$$

The particular solution of equation (1) for the sphere is well known; therefore the reader is referred to the excellent treatment of the series by J. A. Stratton[5] for details. By means of equation (1) we can secure the relationship of wave-length λ to sphere radius a for the first three significant resonance modes. These are:

No. 1. $\alpha = 2\pi/\lambda_a = 1{\cdot}0$
$\lambda = 6{\cdot}28a$
No. 2. $\alpha = 2\pi/\lambda_a = 2{\cdot}30$
$\lambda = 2{\cdot}73a$
No. 3. $\alpha = 2\pi/\lambda_a = 3{\cdot}45$
$\lambda = 1{\cdot}82a$

using the wave-number $2\pi/\lambda$ in standard notation.

Permit the Earth, stripped of its atmosphere, to be considered the spherical matter zone immersed in space. A line x is drawn from the centre of the Earth along the ecliptic plane to terminate at a point o. The length of the line x is $149{\cdot}5 \times 10^6$ km. The source of incident waves is located at point o. For the Earth sphere with a mean radius equal to 6,371·23 km., the first three resonant modes may now be ascertained:

No. 1. $\lambda = 40{\cdot}01 \times 10^6$ m. = 6·28 Earth radii. Frequency = 7·49 cycles/sec.

No. 2. $\lambda = 17{\cdot}39 \times 10^6$ m. = 2·73 Earth radii. Frequency = 17·25 cycles/sec.

No. 3. $\lambda = 11{\cdot}59 \times 10^6$ m. = 1·82 Earth radii. Frequency = 25·88 cycles/sec.

Effects which take place along the line x as the result of electromagnetic resonances of the illuminated Earth are of first interest. For the case of Mie scattering of the Earth at modes 1, 2 and 3, we can determine the magnitude of the secondary field established in the direction of o, compared with a fictitious isotropic scattering body which maintains a constant field $\overline{E^s}$ in all spherical directions φ, θ, when radiating a total power $\overline{P^s}$ isotropic. The scatter field magnitude in the direction o is called backscatter[6] cross-section. Fig. 1 shows the backscatter cross-section σ of a highly conducting sphere (solid line) and that of a water sphere (dotted line) normalized with respect to πa^2.

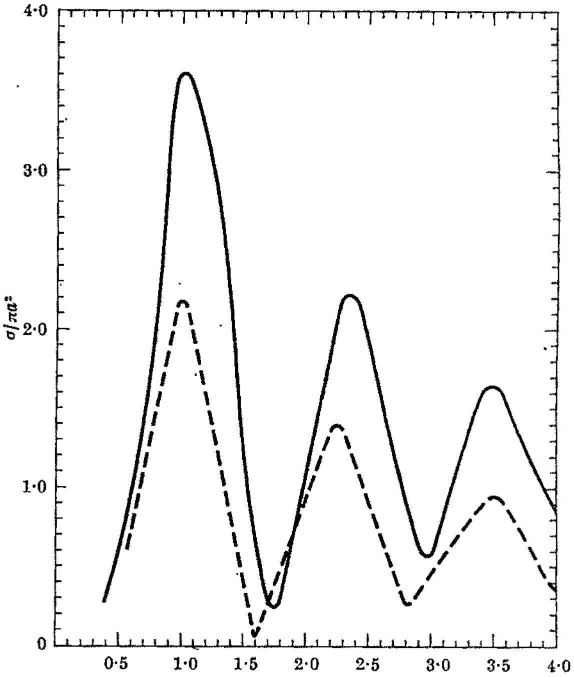

Fig. 1. Backscattering from spheres (from Aden)

a, radius of sphere; $\alpha = Ka = \frac{2\pi}{\lambda} a$

———, Metal sphere; — — —, water sphere

It will be noted that the backscatter cross-section of a sphere illuminated with energy vibrating at frequencies within a critical bandwidth, approximately $\alpha = 0{\cdot}8$ to $\alpha = 6{\cdot}0$, differs markedly from the case of either Rayleigh or specular scatter. Within the critical band, it is seen that peaks and minima are evident in the magnitude of the backscatter cross-section. Again, Fig. 1 discloses that although the electrical constant of the matter making up the spherical body may affect the magnitude of backscatter cross-section it does not sensibly disturb the radius/wave-length relationship of the electromagnetic resonances. The energy scattered back in the direction o will establish electromagnetic standing waves[7] along this axis due to phase interference with the incident field. The intensity of the maxima (loops) of such standing waves will be greater for those wave-lengths within the critical band producing resonance conditions with the Earth sphere, although all finite magnitudes of backscatter field from the Earth will introduce some standing wave phenomenon for frequencies within the illumination spectrum. Emphasis is placed, however, on the very lowest frequency resonances as a decelerating mechanism for high-energy particles.

A. L. Aden[8] has demonstrated the existence of electromagnetic backscatter standing waves produced by water and metal spheres in experiments conducted at a wave-length of 16·23 cm. As the scattered field from the Earth is a spherical wave in the vicinity of the planet, the standing wave which results is damped by radiation. Its configuration, for a single frequency, is therefore a damped sinusoidal wave[9] along the line x, the position of the loops and nodes stationary, with an amplitude variation at a period ω. It must be admitted that employment of an Earth stripped of its atmosphere envelope introduces some grounds for objection to the realism of the model offered so far. In this cursory survey of the theory, only an approximation of the true radius of the Earth scattering shell will be made, for it is clearly evident that rigorous treatment will display a frequency selective term for the extremely low-frequency scatter radius, with complicated entrapped wave effects occurring at the high-frequency end of the spectrum.

The Lyman–Spitzer analysis[10] of the planetary atmosphere shell is selected as a model. The Spitzer atmosphere acts like a gas up to about 600 km., with lighter gases predominating in the atmosphere population above about 300 km. Although free electron densities quoted by authorities differ to some degree, sufficient accuracy here will be attained by use of a density curve with peaks at about 300 km.[11], then decreases at higher altitudes. A mean scattering shell altitude of 300 km. will be selected, producing a total sphere radius of 6,671·23 km. The atmosphere 'corrected' Earth will then introduce resonance modes in the illuminating spectrum at the following wave-lengths:

No. 1. $\lambda = 41{\cdot}89 \times 10^6$ m. = 6·57 Earth radii. Frequency = 7·16 cycles/sec.

No. 2. $\lambda = 18{\cdot}21 \times 10^6$ m. = 2·86 Earth radii. Frequency = 16·47 cycles/sec.

No. 3. $\lambda = 12{\cdot}14 \times 10^6$ m. = 1·9 Earth radii. Frequency = 24·71 cycles/sec.

I am confining attention in this article to the electromagnetic standing waves along line x generated by scatter interference only at wave-lengths Nos. 1, 2 and 3. The position radially from the Earth for each standing wave distribution may be computed or taken directly from the Aden measurements given in the reference. There will be no interaction between such individual frequency fields existing along x if we assume initially that the space k_2 surrounding the planet is free of all charges. This pure field or fictitious state will be labelled the particle-free standing wave case. Under this condition, examination of the polarization characteristics of the incident and scattered wave shows that the conditions for maximum interference between the two fields can exist only within a narrow, solid angle cone pointing toward the point o, with the magnitude of the induced standing wave distribution falling off in other radial directions φ, θ.

Now, let the radiant source at o not only generate electromagnetic waves but also high-energy charged particles, some of which approach the Earth along the incident axis x. J. R. Coleman[12] has examined my matter-induced electromagnetic standing-wave theory in terms of the electron capture mechanism involved in the radio-frequency case. L. M. Kovrizhnykh and V. H. Veksler[13] have studied a similar situation involving capture oscillations of both charged and neutral particles in a radio standing-wave type cyclotron. These analyses emphasize that for a fixed loop field strength of an electromagnetic standing wave the force F exerted on the particle is proportional to wave-length. In terms of decelerator action, Coleman notes that even in the case of a 'solar wind' electron moving at a velocity of 10^6 m./sec. capture will occur when such particle is injected into a radio standing wave the fundamental wave-length of which lies between 10×10^6 and 60×10^6 m. with a loop field-strength of 0·17 V./m. Such extreme particle velocity, of course, is not required in the study of the Van Allen belts found near the Earth, but assumes importance in terms of wave-length/field strength requirements for much larger planets such as Jupiter or Saturn, the first-mode resonance wave-length of which is at least 439×10^6 m. Coleman also makes a preliminary extension of the equivalent black-body temperature of the Sun into the Earth critical spectrum band with encouraging results.

Briefly, then, we have a planetary mass under illumination from a radiant source of large size such as a star, inducing electromagnetic standing waves along the incident direction. Here, individual frequency components of such standing waves do not interact field-wise but do act on the injected charges in such a manner that an integrated force obtains, with the longest wave components of the stationary wave producing first-order effects. Particles injected into such standing-wave envelope region will either be captured if the mass/velocity relationship to wave-length/field strength is critical or be deflected as if by an electromagnetic lens and escape. The requirement for a mechanism to establish the radial Van Allen belts observed about the Earth is still not satisfied, however, by this model, for appreciable magnitude 'capture' fields in the form of large intensity standing waves do not exist at other than the incident axis direction.

However, now let an injected particle, say, an electron, be captured by the incident axis electromagnetic standing wave. Once captured, the electron enters into a steady-state condition which I shall term the particle-wave case. Such particle, as

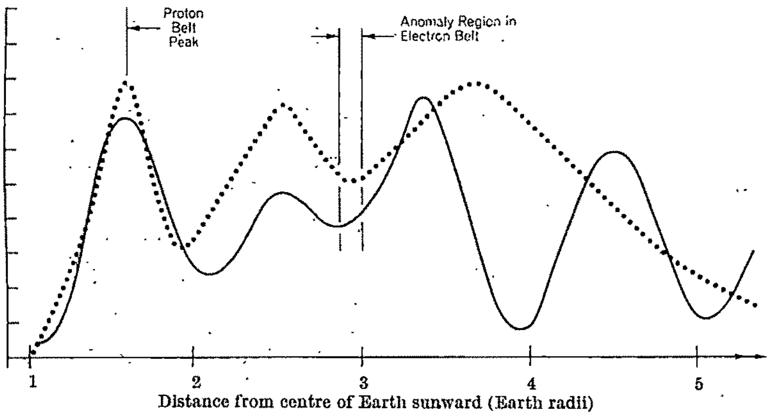

Fig. 2. Distribution of known Van Allen belts compared with calculated wave due to Earth dipole resonance in solar elf electromagnetic illumination
. . . ., Van Allen belt distribution (after Simpson *et al.*); ——, calculated Earth electromagnetic standing wave envelope for modes 1, 2 and 3

Coleman shows, will oscillate along a path concentric with the incident axis x. Studying the Coleman analysis, I realized that by appealing to electromagnetic theory, such an oscillating charged particle becomes a source of current in space. Neglecting the ramifications of the relativistic mass of such oscillating particle in this article, it is clear that the particle becomes a new source of low-frequency radiation in the Earth capture model. Due to the extremely low frequency of the entrapping wave, the particle space current constitutes an extended line source; the Poynting vector of the particle-generated wave must, therefore, lie normal to the incident axis x. Radiation of electromagnetic energy in the direction normal to axis x will introduce increased magnitudes of interference with the sphere scattered wave in a new direction φ, θ displaced off the incident axis. The effect of this interference is to increase the width of the conical standing-wave region pointing to the source. The process is now cumulative in that newly injected particles can be entrapped or else migrate into the widened solid angle zone of standing wave to oscillate along new radial directions. Ultimately, the planet will be surrounded by a set of anular zones of standing waves with loops and nodes distributed radially.

Fig. 2 shows the mathematical average envelope obtained by superimposition of the standing waves resulting solely from resonance modes 1, 2 and 3 of the Earth exosphere scatter model traced as a solid line. The radial distribution of the closest Van Allen belts after Simpson *et al.*[14] is given as a dotted line. It will be seen that a maximum in envelope intensity (loop) exists close to the 1·5 Earth radii position of the known proton belt, and the anomaly in the electron belt at 2·85–3·0 Earth radii is evident without recourse to the Cape Town variation in the Earth magnetostatic field. Beyond 4 Earth radii, the computed field envelope falls off more rapidly than the distribution given by Simpson, with a new maximum produced at about 4·4 Earth radii. It is felt that a model based on the addition of a larger number of critical band frequency components, as well as an extension of the radial distance scale, will fit the known belt distribution more satisfactorily.

Calculations by me of the standing wave distribution in a plane normal to the ecliptic (θ) shows that when the first three resonance modes are superimposed, a deep null or electromagnetic 'pole' occurs at 93 degrees above the radio 'equator' or ecliptic plane of the Earth, permitting deep penetration of particles in the high latitudes.

OBSERVATION OF FAR-INFRA-RED RADIATION FROM SHOCK WAVES

By M. F. KIMMITT, A. C. PRIOR and P. G. SMITH
Royal Radar Establishment, Malvern

INFRA-RED radiation in the wave-length range 0·1–0·6 mm. has been observed in the emission from a plasma generated by a shock wave in argon. This work follows a successful joint experiment with the Atomic Energy Research Establishment, Harwell, in which the emission in the range of wave-lengths 0·1–1·6 mm. was observed from plasmas produced in *Zeta*. The apparatus used was designed for the latter experiment, the details of which are being published elsewhere[1]. The spectra obtained from the observations on the shock tube described here, as from those on *Zeta*, are characteristic of bremsstrahlung, but show regions where the emission is reduced by the black-body limitation.

Under the conditions of these experiments, and in the wave-length region examined, line and band spectra arising from transitions between atomic energy-levels, or between energy-levels of molecules present as impurities, should be absent or insignificant. The observed emission should therefore be due entirely to free-free electron transitions (bremsstrahlung) which, according to the calculations of Gaunt[2]

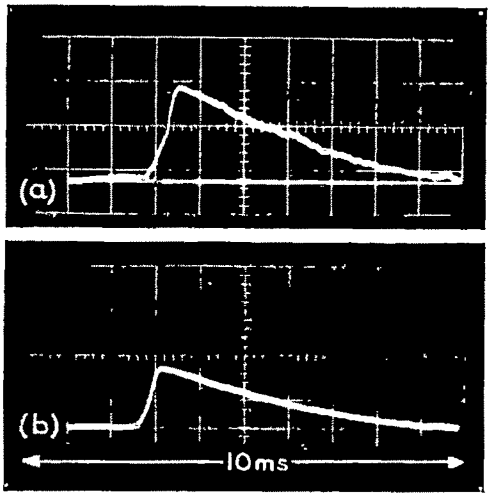

Fig. 1. Oscilloscope traces obtained without spectral resolution. (*a*) Heavily absorbing plasma produced from shock into 1 torr argon. (*b*) Relatively transparent plasma produced from shock into 0·25 torr argon

and Cilliė[3], result in a surface brightness $P_{\text{eff.}}$ given, when $h\nu c \ll kT$, by :

$$P_{\text{eff.}}\ d\nu = 1{\cdot}63 \times 10^{-35}\ Z^2\ g\ T^{-1/2}\ n_e n_i\ d\ d\nu \text{ watts/cm.}^2\text{/steradian/cm.}^{-1} \quad (1)$$

where Z is the ionic charge, T the absolute temperature, n_e and n_i the electron and ion densities, d the plasma thickness, ν the wave number, and g the Gaunt correction factor given by :

$$g = (\sqrt{3}/\pi)\ \ln\ (3kT/2h\nu c)$$

If we take $n_e = n_i = n$, $Z = 1$, and a mean value of 3 for g, these being appropriate to the conditions of the experiment, (1) reduces to :

$$P_{\text{eff.}}\ d\nu = 5 \times 10^{-35}\ n^2\ T^{-1/2}\ d\ d\nu \text{ watts/cm.}^2\text{/steradian/cm.}^{-1} \quad (2)$$

This expression neglects self-absorption, which will prevent the emission from exceeding the black-body value for the appropriate temperature, T; it also neglects plasma resonance effects, and applies only at frequencies sufficiently above that for plasma resonance.

The radiation emerged through a crystal quartz window of diameter 1·5 cm. in the side of the shock tube of 5 cm. diameter, and passed into the spectrometer, which has been briefly described by Roberts[4]; a cone of radiation of half-angle 12° was accepted through the window. The detector was a carbon bolometer similar to that described by Boyle and Rodgers[5], and had a time constant of about 4 msec., the amplified output being displayed on an oscilloscope. The pass band of the spectrometer is normally about 10 per cent of the wave-length to which it is set, but where a greater signal was required in order to examine pulse shapes, the whole spectrum from 0·1 to 1·5 mm. wave-length could be accepted. The energy sensitivity of the system was calibrated by comparison with a black body of known temperature.

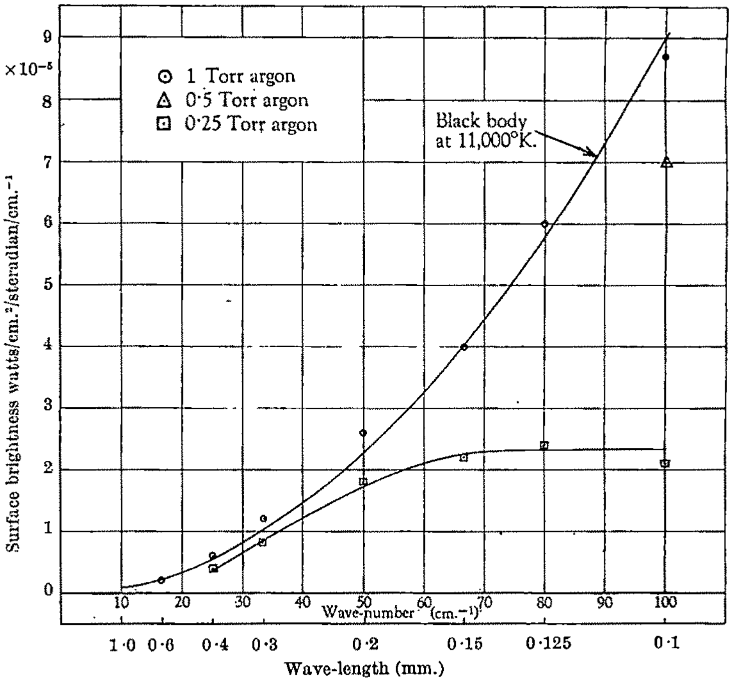

Fig. 2. Observed radiation

The length of heated gas behind the shock front was about 50 cm. as it passed the window, and its velocity about 5×10^6 cm./sec. ; the corresponding transit time of 100 μsec. was much less than the time constant of the detector, which therefore gave an approximately integrated signal. The shock-tube walls are silvered and would be expected to have a reflectivity of 98–99 per cent. For a heavily absorbing plasma, the signal received from the plasma covering the window and filling the spectrometer aperture is preceded and followed by a signal of about half the value, only half the spectrometer aperture being then filled with radiation. This is demonstrated by Fig. 1(*a*), where the steep central portion of the integrated signal is preceded and followed by portions of lower slope. The transit time of the hot gas as deduced from Fig. 1(*a*) agrees with that obtained independently from measurements by resistance thermometer. For a plasma having negligible absorption, and with perfectly reflecting walls, the radiation received should be independent of the position of the shock wave in the tube, since each part of the plasma will fill one or other half of the spectrometer aperture, for all positions of the plasma in the tube. This is demonstrated in Fig. 1(*b*), where no abrupt changes of slope occur but only gradual changes due to imperfect reflectivity.

In principle, the instantaneous radiation intensity can be deduced by measuring the slopes on photographs such as Fig. 1. In practice, the signal was generally too small for this, and instead the peak amplitude was measured and related to the slope by comparison with traces obtained without spectral resolution, where the slopes could be measured ; the results are plotted in Fig. 2. The shock-wave Mach number was measured by means of resistance thermometers spaced either side of the spectrometer aperture at approximately 1 metre apart. At an initial pressure of 1 torr of argon, a Mach number of 15 was measured. From the theoretical calculations of Frood (private communication), these shock-wave conditions should give a temperature of $\sim$ 11,000°K. and an electron density of $\sim 3\times10^{16}$ cm.$^{-3}$, assuming equilibrium to be established in the plasma behind the shock front. For this temperature and density, equation (2) would, for a wave-length of 0·1 mm., give a value of brightness equal to that from a black body if d were put equal to about 1 mm. Thus a black-body spectrum is to be expected, and the experimental points do in fact fit the 11,000°K. black-body curve better than would be anticipated from consideration of likely calibration errors of the spectrometer. Since the available thickness of the plasma, allowing for reflexion from the walls, is $\sim$ 150 cm., any density n greater than $\sim 10^{15}$ cm.$^{-3}$ would be adequate to account for the black-body shape of the spectrum. However, the abrupt changes of gradient in Fig. 1(a) already discussed show that the radiation penetrates only a small portion of the plasma, and this raises the lower density limit to about 2–3×10^{15} cm.$^{-3}$.

For an initial pressure of 0·25 torr of argon, the values of temperature and density calculated from the shock-wave parameters are $T \sim$ 11,000°K. and $n \sim 1\times10^{16}$ cm.$^{-3}$. The approximately flat part of the spectrum indicates that the absorption for the short wave-lengths must be small, as confirmed by the pulse shape (Fig. 1(b)), so that for this region equation (2) should apply; using this with $d = 100$ cm. (shock length $= 35$ cm.) a value of $n \sim 6\times10^{14}$ is obtained. The observations at the longer wave-lengths give good agreement with the calculated temperature. The single observation with an argon pressure of 0·5 torr being slightly below the black-body curve indicates a value of $n \sim 10^{15}$ cm.$^{-3}$ as compared with 2×10^{16} cm.$^{-3}$ deduced from the shock-wave parameters.

All the measurements, both of shock-wave parameters and of radiation, are rather crude time averages for shocks which were probably decaying at a significant rate. Under these conditions, the agreement of the temperature deductions is remarkably good, and the lower densities deduced from the radiation measurements are reasonable, since the calculated densities are for thermal equilibrium, which may well not be reached.

These exploratory measurements have indicated the potential value of far-infra-red spectroscopy for shock-wave plasma diagnostics. Investigations of plasmas with electron densities greater than $\sim 5\times10^{14}$ cm.$^{-3}$, which are beyond the range of standard microwave methods, should be possible, and with a faster detector[6] now being actively developed, much more detailed information should be obtainable than in the present experiments.

PHOTOPRODUCTION OF HYDROGEN, PHOTOFIXATION OF NITROGEN AND A UNIFIED CONCEPT OF PHOTOSYNTHESIS

By Prof. DANIEL I. ARNON, Dr. M. LOSADA, Dr. M. NOZAKI and Dr. K. TAGAWA
Laboratory of Cell Physiology, University of California, Berkeley

BY fractionating isolated chloroplasts, it has been demonstrated experimentally that the overall process of photosynthesis can be separated into a light and a dark phase[1]. The dark phase includes a series of reactions, driven by adenosine triphosphate and reduced triphosphopyridine nucleotide, that convert carbon dioxide into carbohydrate[1-4]. Since the same series of dark reactions is now known to occur also in non-chlorophyllous cells[5,6], it is appropriate to regard carbon dioxide assimilation as another example of cellular activity which is essentially similar in photosynthetic and non-photosynthetic cells. Consequently, carbon dioxide assimilation must be regarded as lying essentially outside the domain of photosynthesis proper[3]. (This conclusion is based on the fact that grana, as contrasted with whole chloroplasts, cannot assimilate carbon dioxide to the level of carbohydrates but retain a capacity for photochemical oxygen evolution and photosynthetic phosphorylation[41]. Our concept would not exclude a *catalytic* participation of carbon dioxide in the mechanism of oxygen evolution as has recently been proposed by Warburg *et al.*[43] and supported by Stern and Vennesland[44].)

What is peculiar to photosynthesis is its light phase. For green plants this comprises the light reactions that produce adenosine triphosphate and reduced pyridine nucleotide[2,7-9]: cyclic photophosphorylation (equation 1) and non-cyclic photophosphorylation (equation 2). The terms 'cyclic' and 'non-cyclic' denote the respective electron-flow mechanisms[10] that we have postulated to explain the experimental findings which are summarized by reactions 1 and 2.

$$n\cdot\text{ADP} + n\cdot\text{H}_3\text{PO}_4 \xrightarrow{\text{light}} n\cdot\text{ATP} \qquad (1)$$

$$2\,\text{TPN} + 2\,\text{ADP} + 2\,\text{H}_3\text{PO}_4 + 2\,\text{H}_2\text{O} \rightarrow 2\,\text{TPNH}_2 + 2\,\text{ATP} + \text{O}_2 \qquad (2)$$

Cyclic photophosphorylation (reaction 1), a reaction that produces only adenosine triphosphate, has been found in every photosynthetic organism tested so far: higher green plants[11-20], algae[21-22] and photosynthetic bacteria[23-28]. This is in agreement with the view presented elsewhere[10,29,30] that cyclic photophosphorylation (reaction 1) is the common denominator of all photosyntheses in plants and in bacteria. By contrast, non-cyclic photophosphorylation, as represented by reaction 2, has thus far been found only in chloroplasts.

The assimilation of carbon dioxide to the level of carbohydrate requires, in addition to adenosine triphosphate, reduced pyridine nucleotide. In isolated chloroplasts, these joint requirements for assimilation of carbon dioxide are satisfied by a combination of cyclic and non-cyclic photophosphorylation[2] (reactions 1 and 2). In photosynthetic bacteria, we have previously investigated only the case in which the electron donor was hydrogen gas. The contribution of light was then limited to the formation of adenosine triphosphate by cyclic photophosphorylation (reaction 1); reduced pyridine nucleotide was formed in a 'dark' reaction, at the expense of hydrogen gas[29]. We had no experimental evidence previously for a non-cyclic photophosphorylation mechanism in photosynthetic bacteria which would be analogous to non-cyclic photophosphorylation in chloroplasts.

The purpose of this article is to present a unified concept of photosynthesis that includes both cyclic and non-cyclic electron-flow mechanisms in photosynthetic bacteria and green plants. Evidence for the operation of a special non-cyclic electron-flow mechanism (without oxygen evolution) in photosynthetic bacteria was obtained by measuring not only photoreduction of pyridine nucleotides[31,32], but also photoproduction of hydrogen and photofixation of nitrogen gas.

Non-cyclic Electron-flow in Bacteria

(*a*) *Photoproduction of hydrogen gas from thiosulphate.* Photoproduction of hydrogen gas by photosynthetic cells was first observed by Gaffron and Rubin in the green alga *Scenedesmus*[33] and by Gest and Kamen in photosynthetic bacteria[34]. In algae, the photoproduction of hydrogen seemed to depend on internal electron donors of metabolic origin[33], whereas photoproduction of hydrogen by photosynthetic bacteria appeared to depend on the presence of exogenous organic acids and carbon dioxide[34-40]. The hydrogen evolved has been thought to arise from a photodecomposition of water[33,40] or from a decomposition of α-ketoglutaric acid[38].

From the point of view of the electron-flow theory of photosynthesis[10,41], which does not involve a photolysis of water, the photoproduction of hydrogen could be viewed as a reduction of H^+ by a hydrogenase with the aid of electrons expelled from excited chlorophyll molecules[41,42]. In accordance with that theory, electrons expelled from chlorophyll would be replaced by electrons donated by cytochromes, which would then become oxidized. The oxidized cytochromes would in turn become reduced by the external electron donors. The cytochrome system in photosynthetic bacteria would thus be a gateway for the entry of electrons and for their transfer to chlorophyll, where they would be raised, at the expense of the energy of absorbed light, to a potential sufficient to reduce H^+ (cf. refs. 41 and 42).

If this interpretation were correct, then photoproduction of hydrogen by photosynthetic bacteria should occur at the expense of simple, physiologically suitable, inorganic electron donors—a possibility for which there was no experimental evidence[37]. We therefore undertook to investigate the photoproduction of hydrogen from thiosulphate by *Chromatium* cells.

Fig. 1 shows that *Chromatium* cytochromes are reduced by thiosulphate, and can serve, therefore, as a point of entry for electrons from that source. Fig. 2 shows that in the light, but not in the dark, gas was evolved by *Chromatium* cells in the presence of thiosulphate. No carbon dioxide was supplied and potassium hydroxide was present in the centre well of the reaction vessel. Evolution of gas ceased when the light was turned off and was resumed when light was turned on again. The gas evolved was identified as hydrogen by adsorption on palladium asbestos[42]. The photoproduction of hydrogen gas was dependent on the concentration of thiosulphate, and was abolished by heating the cells (Fig. 3). The photoproduction of hydrogen gas approached the stoichiometry of reaction 3, that is, for one molecule of thiosulphate used, two electrons and two protons were combined with the aid of hydrogenase and evolved as hydrogen gas.

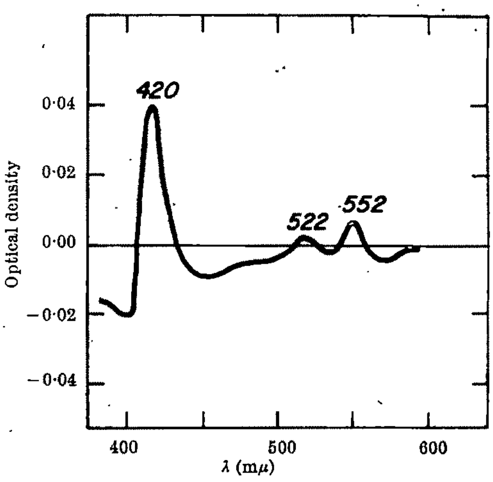

Fig. 1. Reduction of *Chromatium* cytochromes by thiosulphate in a cell-free system. Reaction mixture included, in a final volume of 3·0 ml., 0·1 *M tris* buffer, *p*H 7·8; chromatophores containing 0·1 mgm. bacteriochlorophyll and supernatant fluid corresponding to 0·3 mgm. bacteriochlorophyll. 20 μmoles of thiosulphate were added to one of a pair of Thunberg-type cuvettes and the resulting difference spectrum was measured in a Cary spectrophotometer after 20 min. at room temperature. Gas phase, argon.

The evolution of hydrogen by illuminated *Chromatium* cells showed a marked dependence on *p*H (ref.

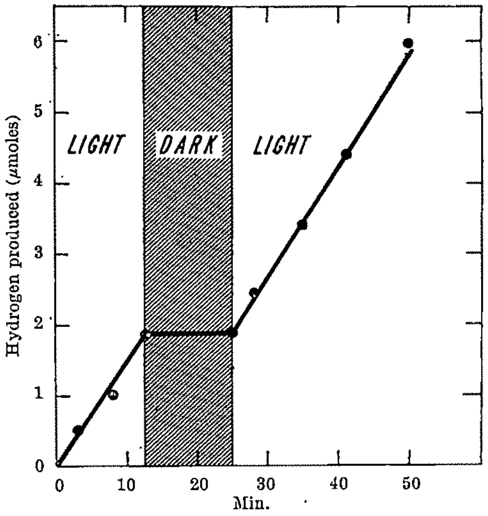

Fig. 2. Light-dependent evolution of hydrogen gas from thiosulphate by *Chromatium* cells. The reaction mixture included 0·1 gm. of washed cells, suspended in 2·6 ml. of a modified nutrient solution from which nitrogen compounds were omitted, 0·3 ml. of 0·5 *M tris* buffer, *p*H 7·2, and 0·1 ml. of 0·2 *M* sodium thiosulphate. 0·1 ml. of 20 per cent potassium hydroxide was put in the centre well of the Warburg manometer flasks. The reaction was run at 30° C. Gas phase, argon. Illumination 50,000 lux

42). The reaction was very vigorous at pH 6·5, but little hydrogen was evolved at pH 8·0.

Photoproduction of hydrogen from thiosulphate was inhibited by nitrogen gas and ammonium ions[42], as is the evolution of hydrogen in the presence of organic electron donors[34,38]. However, neither ammonia nor nitrogen gas inhibited fixation of carbon dioxide by illuminated *Chromatium* cells when thiosulphate was the electron donor. This indicated that, although under the conditions of our experiments ammonia and nitrogen inhibited the flow of electrons to H^+, they did not inhibit the flow of electrons that is required for assimilation of carbon dioxide by way of pyridine nucleotide.

Growing *Chromatium* cells were found, by analysis, to have oxidized in four days 27 millimoles of added thiosulphate to 54 millimoles of sulphate. During this period the appearance of the culture indicated a transitional formation of elemental sulphur. The results are in agreement with the following sequence of reactions, in which thiosulphate is the donor of electrons that are activated by light and used either for the assimilation of carbon and nitrogen into cellular substance or for the photoproduction of hydrogen gas:

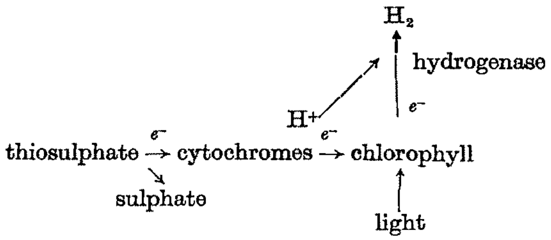
$$S_2O_3^= + 2\,OH^- \xrightarrow{\text{light}} S + SO_4^= + 2\,e^- + H_2O \quad (3)$$

$$S + 8\,OH^- \xrightarrow{\text{light}} SO_4^= + 6\,e^- + 4\,H_2O \quad (4)$$

$$10\,H_2O \xrightarrow{\text{dark}} 10\,H^+ + 10\,OH^- \quad (5)$$

$$\text{Sum: } S_2O_3^= + 5\,H_2O \xrightarrow{\text{light}} 2\,SO_4^= + 8\,e^- + 10\,H^+ \quad (6)$$

The proposed electron-flow mechanism[42] for the photoproduction of hydrogen from thiosulphate envisages the following electron transfer:



The results with thiosulphate provided the first experimental evidence for hydrogen evolution dependent on light, from an 'inorganic' electron donor by a photosynthetic organism. Similar results were obtained when thiosulphate was replaced by succinate as electron donor[41].

It appears, therefore, that *Chromatium* uses light energy to raise electrons, supplied by thiosulphate to chlorophyll, via cytochromes, to a reducing potential at least equal to that of molecular hydrogen. We have also observed evolution of hydrogen gas in the *dark* by cell-free *Chromatium* preparations when the electron donor was dithionite, a substance that provides electrons capable of reducing protons without requiring additional energy (a catalytic amount of benzyl viologen was used as an electron carrier in this dark reaction).

(*b*) *Photofixation of nitrogen gas.* Nitrogen fixation by photosynthetic organisms (refs. 45, 35, 38, 46–49) may also be viewed as resulting from a non-cyclic electron-flow in which electrons pass from an external electron donor, via cytochromes, to chlorophyll excited by light, and thence to molecular nitrogen.

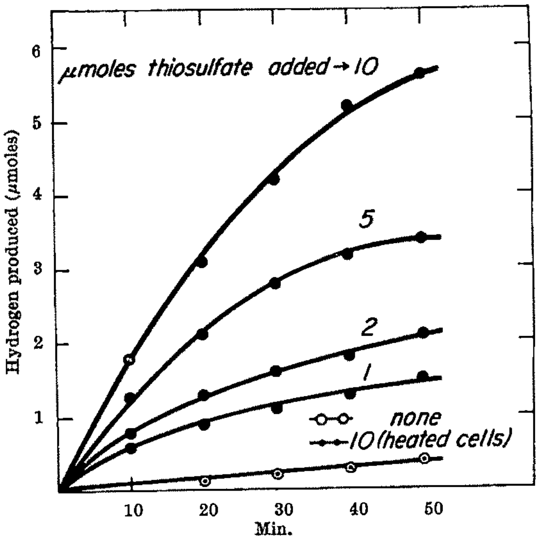


Fig. 3. Photoproduction of hydrogen gas by *Chromatium* cells as a function of added thiosulphate. The control vessel contained cells that had been heated at 100° C. for 10 min. Other experimental conditions are as described for Fig. 2

This interpretation was substantiated by using thiosulphate and succinate as electron donors for fixation of nitrogen gas by illuminated *Chromatium* cells[50]. Fig. 4 shows the result of photofixation of nitrogen gas with thiosulphate as the electron donor. Similar photofixation of nitrogen was obtained with succinate as the electron donor. In both cases, *Chromatium* cells fixed nitrogen only in light. Fixation ceased when the light was turned off and was resumed when the light was turned on again. The dependence of nitrogen fixation on light and an external electron donor was confirmed by the use of nitrogen-15 isotope (Table 1). We are indebted to Dr. C. C. Delwiche for the determinations of nitrogen-15.

In the case of thiosulphate, photofixation of nitrogen was greatly increased by the addition of oxalacetate (Fig. 4), which probably acted as an amino-group acceptor. Succinate served both as electron

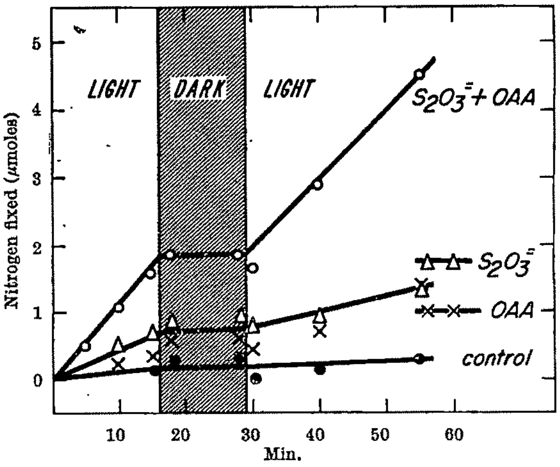

Fig. 4. Effect of thiosulphate and oxalacetate on photofixation of nitrogen gas by *Chromatium* cells. The reaction mixture included in a final volume of 2·9 ml., 0·1 gm. of washed cells, suspended in a modified nutrient solution, pH 7·2 (from which nitrogen compounds were omitted). 20 micromoles each of thiosulphate and oxalacetate were added as indicated. 0·1 ml. of 20 per cent potassium hydroxide was put in the centre well of the Warburg manometer flasks. The reaction was run at 30° C. Gas phase, nitrogen. Illumination 50,000 lux

Table 1. EFFECT OF LIGHT AND ELECTRON DONORS ON FIXATION OF NITROGEN GAS BY *Chromatium* CELLS

Treatment	Nitrogen-15 atom per cent excess
Dark, succinate	0·004
Dark, thiosulphate + oxalacetate	0·003
Light	0·288
Light, succinate	1·049
Light, thiosulphate + oxalacetate	1·467

40 micromoles each of thiosulphate, oxalacetate and succinate were added as indicated. Other experimental conditions as in Fig. 4, except that no potassium hydroxide was included, and the gas atmosphere was 90 per cent argon and 10 per cent nitrogen containing 30 atom per cent excess nitrogen-15. Reaction time was 2 hr.

donor and as a source of the carbon skeleton that is needed for accepting an amino-group.

In preliminary experiments, when cell-free *Chromatium* preparations were supplied in the 'dark' with a mixture of hydrogen and nitrogen gas, they absorbed more gas than in the control treatment in which the gas phase consisted solely of hydrogen. This seems to indicate that cell-free *Chromatium* preparations can fix nitrogen, with the aid of hydrogen gas as the electron donor—an interpretation that was in agreement with experiments using nitrogen-15 (Table 2). Photofixation of nitrogen-15 by cell-free *Chromatium* preparations, although low by comparison with that by whole cells (Table 1) was above the level of significance of isotopic identification with the mass spectrometer used.

Table 2. NITROGEN-15 FIXATION IN THE DARK BY CELL-FREE EXTRACTS OF *Chromatium*

No.	Reductant added	Nitrogen-15 atom per cent excess Experiment *A*	Experiment *B*
1	None	0·0255	0·0274
2	Reduced diphosphopyridine nucleotide	0·0480	
3	Hydrogen gas	0·0362	0·0430

The reaction mixture contained in a final volume of 3 ml.: cell-free extract, containing 0·3 mgm. bacteriochlorophyll, and the following in micromoles: *tris* buffer, *p*H 7·8, 100; magnesium chloride, 5; benzyl viologen, 0·2. Vessels 1 and 3 received 0·5 μmole diphosphopyridine, and vessel 2, 1 μmole reduced diphosphopyridine nucleotide. All vessels received 0·5 atmosphere nitrogen containing 96 atom per cent excess nitrogen-15. Treatment 3 received in addition 0·5 atmosphere hydrogen gas. The experiment was run at 25° C. for 2 hr. in the dark.

These findings appear to support the view that the role of light in photofixation of nitrogen by *Chromatium* is to generate electrons with a reducing potential that is at least equal to that of hydrogen. When exogenous hydrogen was supplied in the gas phase in the dark, light was no longer necessary for the fixation of nitrogen. Pyridine nucleotides seemed to mediate the reduction of nitrogen. However, the experiments on nitrogen fixation by cell-free *Chromatium* preparations are at an early stage and it would be premature to draw final conclusions.

(*c*) *Photoreduction of pyridine nucleotides.* The photoreduction of diphosphopyridine nucleotide was observed by Frenkel[31] and Vernon and Ash[32] in *Rhodospirillum rubrum*, and by Ogata *et al.*[51] in *Chromatium*. In more recent experiments we have found that in the presence of succinate and light, unwashed chromatophores from *R. rubrum*, unaided by enzymes from chloroplasts (cf. ref. 32), reduce both di- and tri-phosphopyridine nucleotide.

We have previously emphasized[10,29] that *Chromatium* is capable of reducing pyridine nucleotide in the dark, when supplied with exogenous electron donors, such as hydrogen gas, which yield electrons at the redox-level of pyridine nucleotide. The reduction of pyridine nucleotide is dependent on light when photosynthetic bacteria are supplied with exogenous electron donors, such as succinate, which yield electrons at a redox-level insufficient for reducing pyridine nucleotide without an additional input of energy. It should be noted, however, that in the case of succinate, the relatively low redox potential characterizes only the first oxidation step, that to fumarate. As fumarate is transformed to malate, *Chromatium* can use it to reduce pyridine nucleotide in the dark[29].

Experiments with cell-free systems of *R. rubrum*, to be reported elsewhere (Nozaki, M., Tagawa, K., and Arnon, D. I.), indicate that the non-cyclic electron transport in photosynthetic bacteria that results in pyridine nucleotide reduction is coupled with formation of adenosine triphosphate, thus providing a parallel to non-cyclic photophosphorylation in chloroplasts[7-9]. Experiments are now under way to determine whether the formation of adenosine triphosphate is also coupled with the non-cyclic electron transport that results in the photoproduction of hydrogen or photofixation of nitrogen gas.

To recapitulate, the reduction of pyridine nucleotides, the fixation of nitrogen and the evolution of hydrogen from such electron donors as thiosulphate or succinate are reactions that in photosynthetic bacteria have been found to require an input of light-energy. These photochemical reactions suggest the existence of a non-cyclic electron-flow mechanism in photosynthetic bacteria as represented diagrammatically in Fig. 5.

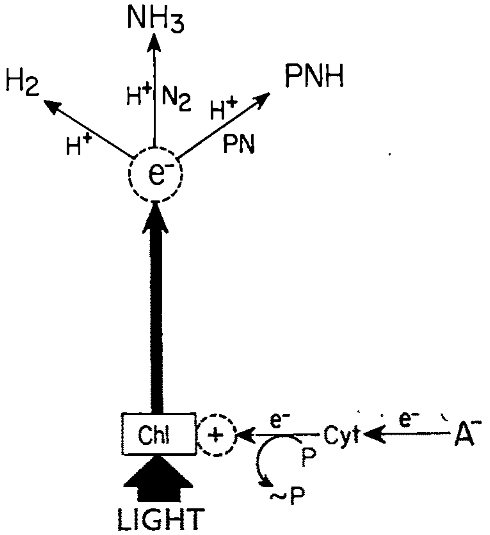

Fig. 5. Scheme for non-cyclic electron flow in *Chromatium*. Details in the text

Non-cyclic Electron Flow and the Evolution of Photosynthesis

Until recently, cyclic photophosphorylation was the only experimentally demonstrable common denominator of the mechanism of photosynthesis in plants and bacteria. Now it has become clear that photosynthetic bacteria may also use part of the absorbed light-energy for a non-cyclic photophosphorylation that is analogous in some respects to that found in chloroplasts.

The most characteristic difference between the non-cyclic electron-flow mechanism of chloroplasts (reaction 2) and bacteria (Fig. 5) is in the electron donor system. In chloroplasts the electron donor is water (that is, OH-), whereas bacteria cannot use water but employ inorganic or organic electron donors such as thiosulphate or succinate[52,53].

This interpretation of the difference between the non-cyclic electron-flow mechanism in chloroplasts and in photosynthetic bacteria is supported by recent evidence, presented in the succeeding article by M. Losada, F. R. Whatley and D. I. Arnon, that it is experimentally possible to replace water as the electron donor in non-cyclic photophosphorylation by chloroplasts and to demonstrate in this manner a bacterial type of non-cyclic electron flow in green plants: a reduction of pyridine nucleotide coupled with the oxidation of an exogenous electron donor and a simultaneous photophosphorylation but without evolution of oxygen.

These findings permit us to interpret with somewhat enhanced confidence, certain aspects of the biochemical evolution of photosynthesis which we have already discussed elsewhere[7,29].

The beginning of photosynthesis may be viewed as an emergence of a porphyrin that gave rise to chlorophyll and permitted the cell to use for metabolic purposes the energy of sunlight. In this primitive photosynthesis, the contribution of light-energy was probably limited to anaerobic cyclic photophosphorylation. No photochemically formed reductant would have been required for the photoassimilation of, say, acetate or for the assimilation of carbon dioxide so long as hydrogen gas was present in the atmosphere[29]. Oparin[54] and Miller and Urey[55] have summarized the evidence that in the early periods of the evolution of life the environment contained simple carbon compounds such as acetate and also hydrogen gas. Photosynthetic bacteria still show this primitive type of photosynthesis. *Chromatium*, for example, when supplied with hydrogen gas, uses it to reduce pyridine nucleotide in the dark, and seems then, as in the case of photoassimilation of acetate, to limit the use of light to the formation of adenosine triphosphate[29] (cf. ref. 30).

As hydrogen gas vanished from the primitive atmosphere, the photosynthetic cell probably became dependent on the photosynthetic apparatus for generating photochemically a strong reductant from such electron donors as succinate or thiosulphate. Light-energy now would have served a dual purpose: it would supply adenosine triphosphate by cyclic photophosphorylation and would also, by photooxidizing the electron donor, provide electrons for reducing pyridine nucleotides by a non-cyclic electron-flow mechanism. In organisms which contain, or can form adaptively, hydrogenase or nitrogenase (photosynthetic bacteria and algae), this phase of photosynthesis can be observed to-day as a photoproduction of molecular hydrogen or a photofixation of nitrogen gas.

The non-cyclic electron-flow mechanism in photosynthetic bacteria operates with such electron donors as reduced sulphur compounds or organic acids. Water (OH^-) became an electron donor only with the emergence of plant photosynthesis. As will be discussed in the following article, it now appears that this event was made possible because plants have evolved an auxiliary reaction dependent on light, in which the electrons from water (OH^-) are first raised to a potential similar to that of the electron donors in bacterial photosynthesis, and are then used in a second photochemical reaction—the non-cyclic electron flow common to plants and bacteria—in which pyridine nucleotide reduction is coupled with the formation of adenosine triphosphate.

Oxygen evolution is peculiar to green plants because it is the product of an auxiliary photochemical reaction, the oxidation of water (OH^-), that is found only in green plants. Water as an electron donor is therefore not involved in the two main events of non-cyclic photophosphorylation in plants and bacteria, the photoreduction of pyridine nucleotide and the coupled formation of adenosine triphosphate.

In both bacterial and plant photosynthesis the photosynthetic events proper are limited to the formation of adenosine triphosphate and reduced pyridine nucleotide by cyclic and non-cyclic photophosphorylation. This transformation of light into the common currency of cellular energy is fundamentally independent of carbon dioxide assimilation. There is no particular reason why adenosine triphosphate or a photochemically generated reductant could not be used for driving endergonic cellular processes other than carbon dioxide assimilation.

In summary, the differences between bacterial and plant photosynthesis seem to centre on the electron donors that are consumed in the reduction of pyridine nucleotide. With some electron donors, as, for example, hydrogen gas, the reduction of pyridine nucleotide by photosynthetic bacteria is a dark reaction. With other electron donors, such as thiosulphate or succinate, an input of light-energy, in a non-cyclic electron-flow mechanism, becomes necessary for the oxidation of the electron donor and the reduction of pyridine nucleotide. Thus, in bacterial photosynthesis, the reduction of pyridine nucleotide may occur with or without an input of light energy depending on the particular electron donor used. By contrast, in photosynthesis of green plants, the reduction of pyridine nucleotide invariably requires an input of light energy because the physiological electron donor is water (OH^-).

This investigation was aided by grants from the National Institutes of Health and the Office of Naval Research.

SEPARATION OF TWO LIGHT REACTIONS IN NONCYCLIC PHOTO-PHOSPHORYLATION OF GREEN PLANTS

By Dr. M. LOSADA, Dr. F. R. WHATLEY and Prof. DANIEL I. ARNON

Laboratory of Cell Physiology, University of California, Berkeley

NONCYCLIC photo-phosphorylation[1-3] is a photochemical reaction in isolated chloroplasts which yields simultaneously three products: reduced pyridine nucleotide, adenosine triphosphate and oxygen, in accordance with reaction 1 (where P means orthophosphate):

$$\mathrm{ADP} + \mathrm{P} + \mathrm{TPN} + \mathrm{H_2O} \rightarrow \mathrm{ATP} + \mathrm{TPNH_2} + \tfrac{1}{2}\,\mathrm{O_2} \qquad (1)$$

Of the three products of reaction 1, only reduced pyridine nucleotide and adenosine triphosphate are required by chloroplasts in the conversion of carbon dioxide to carbohydrate[4-7]. Oxygen is an excreted by-product, incidental to the use of water ($\mathrm{OH^-}$) as the electron donor in noncyclic photo-phosphorylation by chloroplasts[8]. Photosynthetic bacteria cannot use water as an electron donor, and here the key events of noncyclic photo-phosphorylation—the reduction of pyridine nucleotide and the formation of adenosine triphosphate—also occur, but are not accompanied by an evolution of oxygen (ref. 9 and unpublished work by Nozaki, M., Tagawa, K., and Arnon, D. I.).

Vernon and Zaugg[10], extending the earlier work of Vernon and Kamen[11], have shown that chloroplasts which have lost, through ageing or by poisoning, the capacity to evolve oxygen photochemically, are nevertheless able to reduce triphosphopyridine nucleotide photochemically with electrons donated by a reduced dye, 2,6-dichlorophenol indophenol. (In practice, the dye is supplied in catalytic amounts and kept in a reduced form by substrate amounts of added ascorbate.) Krasnovsky has found that chlorophyll solutions in pyridine can bring about a photochemical electron transfer from ascorbate or other electron donors to pyridine nucleotides or other electron acceptors[12].

We now wish to report that noncyclic photo-phosphorylation in chloroplasts has been experimentally separated into two distinct photochemical reactions: (*a*) a photo-oxidation of water ($\mathrm{OH^-}$) that yields oxygen (reaction 2) and (*b*) a noncyclic photo-phosphorylation of the bacterial type, that is, a photo-reduction of triphosphopyridine nucleotide that is coupled with the formation of adenosine triphosphate (reaction 3). The two reactions have been separated by using reduced (A^-) and oxidized (A) indophenol dyes as summarized here:

$$\mathrm{H_2O} + 2A \xrightarrow{\text{light}} \tfrac{1}{2}\,\mathrm{O_2} + 2A^- + 2\mathrm{H^+} \qquad (2)$$

$$2A^- + \mathrm{TPN} + 2\mathrm{H^+} + \mathrm{ADP} + \mathrm{P} \xrightarrow{\text{light}} \mathrm{TPNH_2} + \mathrm{ATP} + 2A \qquad (3)$$

$$\text{Sum: } \mathrm{TPN} + \mathrm{ADP} + \mathrm{P} + \mathrm{H_2O} \xrightarrow{\text{light}} \mathrm{ATP} + \mathrm{TPNH_2} + \tfrac{1}{2}\,\mathrm{O_2} \qquad (1)$$

Bacterial Type of Noncyclic Electron Flow in Chloroplasts

Table 1 shows that when catalytic amounts of 2,6-dichlorophenol indophenol[10] replaced water ($\mathrm{OH^-}$) as the electron donor (treatment 3), illuminated chloroplasts formed adenosine triphosphate and reduced triphosphopyridine nucleotide without evolving oxygen. Similar results were obtained when reduced 2,3′,6-trichlorophenol indophenol[13] was used instead of 2,6-dichlorophenol indophenol. The participation of water as an electron donor in these reactions was blocked by the addition of *p*-chlorophenyl dimethylurea[10] to, and the omission of chloride[14] from, the reaction mixture. When the participation of water as an electron donor was not blocked (Table 1, treatment 1), the reduction of triphosphopyridine nucleotide and the coupled phosphorylation were accompanied by evolution of

Table 1. NONCYCLIC PHOTO-PHOSPHORYLATION OF THE BACTERIAL TYPE BY CHLOROPLASTS

No.	Addenda	Effective electron donor	Oxygen evolved (μatoms)	Triphosphopyridine nucleotide reduced (μmoles)	Adenosine triphosphate formed (μmoles)
1	None	Water	3·0	3·4	2·4
2	Chlorophenyl dimethyl urea	None	0	0·5	0·2
3	Dye, ascorbate, chlorophenyl dimethyl urea	Reduced dye (ascorbate)	0	3·2	3·4

Vessel 1 contained in a total volume of 3 ml.: washed chloroplast fragments (*P*1*S*2), prepared in the absence of chloride, containing 0·5 mgm. chlorophyll; 0·05 ml. purified spinach phosphopyridine nucleotide reductase, and the following, in micromoles: *tris*/acetate buffer, *p*H 8·0, 40; $MgSO_4$, 5; $K_2H^{32}PO_4$, 10; ADP, 10; TPN, 4; and KCl, 10. In vessel 2, KCl was omitted and 2×10^{-5} *M* *p*-chlorophenyl dimethylurea was added. Treatment 3 was the same as treatment 2 except that 20 μmoles ascorbate and 0·2 micromole dye (dichlorophenol indophenol) were added. The experiment was run for 20 min. at 15° (at a light intensity of 2,000 ft. candles). Oxygen was measured manometrically and triphosphopyridine nucleotide spectrophotometrically at 340 mμ.

The omission of chloride and the addition of chlorophenyl dimethyl urea, a powerful inhibitor of oxygen evolution, blocked the use of water as an electron donor in the chloroplast system. Catalytic amounts of dichlorophenol indophenol served as an electron carrier between ascorbate and the chloroplast system.

oxygen. When the participation of water was blocked but no substitute electron donor was supplied (treatment 2), no significant reaction occurred at all.

The 'bacterial' type of noncyclic electron-flow mechanism that is envisaged as operating in chloroplasts, when the participation of water as the electron donor is blocked (Table 1, treatment 3), is illustrated diagrammatically in Fig. 1. The electron donor, A^-, represents the reduced indophenol dye, and the electron acceptor, *B*, represents triphosphopyridine nucleotide (cf. reaction 3). In accordance with previous formulations, we envisage the formation of adenosine triphosphate as occurring during the electron transport between cytochromes and chlorophyll[15].

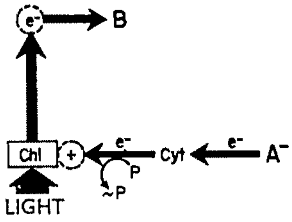

Fig. 1. Scheme for noncyclic photo-phosphorylation of the bacterial type. Details in the text

Photo-oxidation of Water as a Separate Reaction

In the experiments just described, catalytic amounts of phenol indophenol dye mediated the transfer of electrons from ascorbate to triphosphopyridine nucleotide. The dye was *reduced in the dark* by ascorbate and *oxidized in the light* by triphosphopyridine nucleotide. This electron transport was coupled with the formation of adenosine triphosphate (reaction 3).

We will now describe experiments in which catalytic amounts of phenol indophenol dye mediated the transfer of electrons from water (OH^-) to ferricyanide. The dye was *reduced in the light* by water (OH^-) (resulting in an evolution of oxygen) and was *oxidized in the dark* by ferricyanide. This photo-oxidation of water did not result in the formation of adenosine triphosphate (reaction 2).

Indophenol dyes have long been known to be reduced photochemically by chloroplasts[13,16] in a Hill reaction; but unlike such Hill reagents as ferricyanide[1–3], the photo-reduction of 2,3′,6-trichlorophenol indophenol is not linked with photo-phosphorylation[13,17]. Krogmann and Jagendorf[13] drew from this "the inference . . . that reduction of indophenol dye is primarily by means of uncoupled electron transport", possibly by a " 'short circuit' of that part of the electron transport system which is coupled to phosphorylation".

We have examined the effect of catalytic amounts of indophenol dyes on a variant of noncyclic photophosphorylation in chloroplasts where ferricyanide replaces triphosphopyridine nucleotide (reaction 4).

$$2Fe^{3+}Cy + H_2O + ADP + P \xrightarrow{\text{light}} 2Fe^{2+}Cy + \tfrac{1}{2}\,O_2 + ATP + 2H^+ \quad (4)$$

The results are shown in Table 2. The addition of catalytic amounts of indophenol dye to the ferricyanide system has almost completely suppressed the formation of adenosine triphosphate without impairing oxygen evolution (treatments 2 and 4). The addition of catalytic amounts of indophenol dye has thus converted the noncyclic photo-phosphorylation reaction with ferricyanide into a more limited reaction, a photo-oxidation of water that is not accompanied by photo-phosphorylation.

Table 2. SEPARATION OF PHOTO-PRODUCTION OF OXYGEN AND PHOTO-PHOSPHORYLATION BY CHLOROPLASTS

No.	Treatment	Effective electron acceptor	Oxygen produced (μatoms)	Adenosine triphosphate formed (μmoles)
1	Ferricyanide	Ferricyanide	4·5	4·7
2	Ferricyanide Dye A +	Oxidized dye (Ferricyanide)	5·1	1·3
3	Ferricyanide	Ferricyanide	3·3	3·5
4	Ferricyanide Dye B +	Oxidized dye (Ferricyanide)	3·5	0·8

The reaction mixture contained, in a final volume of 3 ml., unwashed chloroplast fragments containing 0·2 mgm. chlorophyll, and the following in micromoles: *tris*/HCl buffer, *p*H 8, 100; $MgSO_4$, 5; $K_2H^{32}PO_4$, 10; adenosine diphosphate, 10; potassium ferricyanide, 10. Dye *A* (0·2 μmole 2,6-dichlorophenol indophenol) or dye *B* (0·05 μmole 2,3′,6-trichlorophenol indophenol) was added where indicated. 10 per cent potassium hydroxide was present in the centre well of the manometer vessels. The reaction was run for 12 min. at 15° C. in the light (2,000 ft. candles). The gas phase was nitrogen.

In the experiments illustrated in Table 2, it was possible to measure the oxygen evolution that accompanies the photo-reduction of indophenol dyes because they were supplied in catalytic amounts and were kept in the oxidized state by the presence of substrate amounts of ferricyanide. A direct measurement of oxygen evolution that accompanies the photo-reduction of 2,6-dichlorophenol—or 2,3′,6-trichlorophenol indophenol—is difficult to make because these dyes, when used in concentrations that are required for manometric measurements of evolved oxygen, absorb too much light. This reduces the effective light intensity to such an extent that chloroplasts cease to evolve oxygen[16]. Indophenol dyes are therefore generally used as Hill reagents in low concentrations, and their photo-reduction is measured not manometrically by oxygen evolution but optically, by their decolorization[16,18].

The observed effect of indophenol dyes could not be attributed to inhibiting, uncoupling, 'shortcircuiting' or by-passing a phosphorylation step in reaction 4. As shown in Table 3, the addition of indophenol dyes to the noncyclic photo-phosphorylation system with triphosphopyridine nucleotide (reaction 1) did not suppress photo-phosphorylation and has, in fact, slightly increased it. As in the ferricyanide system (Table 2), the addition of the dye to the triphosphopyridine nucleotide system did not affect the oxygen evolution.

Table 3. EFFECT OF INDOPHENOL DYES ON NONCYCLIC PHOTO-PHOSPHORYLATION BY CHLOROPLASTS IN THE PRESENCE OF TRIPHOSPHOPYRIDINE NUCLEOTIDE (TPN)

No.	Treatment	Effective electron acceptor	Oxygen produced (μatoms)	Adenosine triphosphate formed (μmoles)
1	TPN	TPN	3·3	3·2
2	TPN Dye *A* +	TPN	3·1	4·2
3	TPN	TPN	3·0	3·3
4	TPN Dye *B* +	TPN	3·1	3·6

Experimental conditions were the same as for Table 2, except that the ferricyanide was omitted. 4 μmoles TPN and 0·1 ml. of a purified preparation of triphosphopyridine nucleotide reductase from spinach were added in each treatment.

The photo-oxidation of water is diagrammatically represented in Fig. 2, where *A* stands for oxidized dye. The reaction requires chloride. We regard the photo-oxidation of water by chloroplasts as an auxiliary reaction to supply electrons at an elevated reducing potential for a second photochemical reaction, the bacterial type of noncyclic photo-phosphorylation, during which a phosphorylation, coupled with the reduction of pyridine nucleotide, actually occurs (Fig. 1).

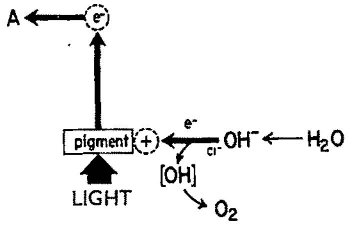

Fig. 2. Scheme for photo-oxidation of water by chloroplasts. Details in the text.

It appears that noncyclic photo-phosphorylation in green plants combines the two component photochemical reactions: (*a*) the auxiliary reaction for photo-oxidation of water (Fig. 2) and (*b*) the bacterial type of noncyclic photo-phosphorylation (Fig. 1) that is used both by photosynthetic bacteria and by green plants for photo-reduction of pyridine nucleotide and a coupled phosphorylation.

Fig. 3 depicts the combined scheme for noncyclic photo-phosphorylation in green plants that we now envisage. *B* is the electron acceptor, triphosphopyridine nucleotide under physiological conditions, but it can be replaced in cell-free systems by ferricyanide. Under special conditions, molecular oxygen can also serve as the electron acceptor *B* in cell-free systems, and this would result in an "oxidative photosynthetic phosphorylation"[17] (compare Fig. 1) or "oxygen-catalysed cyclic photo-phosphorylation"[19] (compare Fig. 3). In the latter case an oxygen exchange reaction would result. The consumption of oxygen at one end (*B* in Fig. 3) would balance the production of oxygen at the other (bottom of Fig. 3).

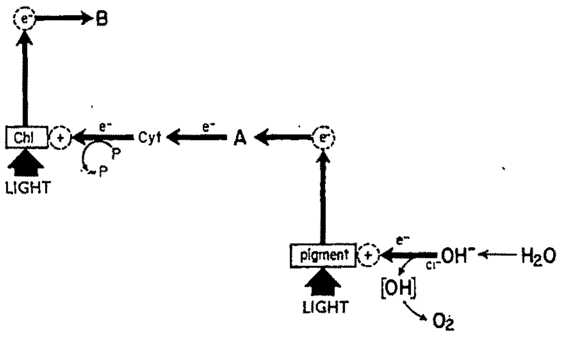

Fig. 3. Scheme for noncyclic photo-phosphorylation in green plants. Details in the text

The intermediate *A* in Fig. 3 is both the electron acceptor for the first, and the electron donor for the second, light reaction (compare Figs. 1 and 2). We have used indophenol dye as an experimental device to separate the two photochemical reactions. The natural intermediates with which the dyes have interacted have not been identified. They may include cytochromes or a quinone[20].

According to the scheme shown in Fig. 3, electron acceptors in chloroplast reactions may be divided into those which react in position *B* and those which react in position *A*. Only the first group, exemplified by triphosphopyridine nucleotide, would give a coupled photo-phosphorylation. 2,3′,6-Trichlorophenol indophenol[13,17] is an example of the second group. However, certain compounds, although reacting preferentially in position *A*, may also be capable of reacting in position *B*.

Since indophenol dyes are reduced by illuminated chloroplasts much more rapidly than ferricyanide[13,21], a catalytic amount of the dye can convert noncyclic photo-phosphorylation with ferricyanide into a photo-oxidation of water reaction (Table 2). In the absence of the dye, ferricyanide acts as a terminal electron acceptor *B* in noncyclic photo-phosphorylation, and oxygen evolution is accompanied by formation of adenosine triphosphate (cf. Fig. 3 and Table 2, treatments 1 and 3). When the dye is present, it is repeatedly reduced during the photo-oxidation of water and re-oxidized by ferricyanide in the dark (cf. Fig. 2 and Table 2, treatments 2 and 4). Here oxygen is produced without the formation of adenosine triphosphate (Fig. 2). However, indophenol dyes do not convert noncyclic photophosphorylation with triphosphopyridine nucleotide into a photo-oxidation of water reaction (Table 3). The dark re-oxidation of the reduced dye by triphosphopyridine nucleotide is precluded by the difference in the respective normal redox potentials (0·217 V. for 2,6-dichlorophenol indophenol and −0·320 V. for triphosphopyridine nucleotide).

Triphosphopyridine Nucleotide Reductase from *Chromatium*

The separation in chloroplasts of the photo-phosphorylation reaction from the photo-oxidation of water underlines the similarities and the differences between noncyclic electron-flow mechanisms in photosynthetic bacteria and in green plants. The difference is most pronounced at the electron donor end, where green plants, but not photosynthetic bacteria, can use water (OH⁻) as the electron donor.

Unlike photosynthetic bacteria, chloroplasts contain neither nitrogen-fixing enzymes nor hydrogenase.

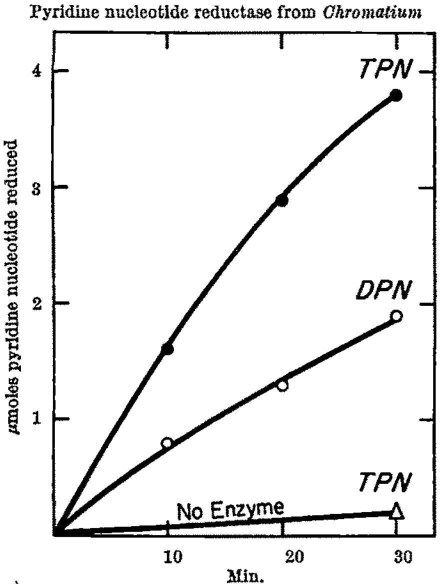

Fig. 4. Pyridine nucleotide reductase from *Chromatium*. Experimental conditions as in Table 4, except that $K_2H^{32}PO_4$ and ADP were omitted. 4 μmoles DPN or TPN were added as indicated

As a consequence, the electron acceptor end of the noncyclic electron-flow mechanism in chloroplasts can be coupled neither to photofixation of nitrogen nor to photoproduction of hydrogen gas, but only to reduction of pyridine nucleotide. However, certain species of green and blue-green algæ constitute exceptions among plants. They can fix nitrogen photosynthetically or they can become adapted to using hydrogen gas as a reductant in photosynthesis (literature cited in ref. 9).

Despite the differences in enzymic composition that govern nitrogen fixation and hydrogen utilization, the noncyclic electron-flow mechanisms in bacteria and chloroplasts are basically similar at the electron acceptor end. This view is strengthened by the recent isolation of a photosynthetic pyridine nucleotide reductase from *Chromatium* and *R. rubrum*. As shown in Fig. 4, the bacterial enzyme catalysed the photochemical reduction of pyridine nucleotides by chloroplasts that have been deprived of their own pyridine nucleotide reductase. When tested by adding to washed chloroplasts, the bacterial pyridine nucleotide reductase was similar to the chloroplast pyridine nucleotide reductase in reducing preferentially triphosphopyridine nucleotide over diphosphopyridine nucleotide[22,23].

The reduction of triphosphopyridine nucleotide was coupled with oxygen evolution when the bacterial enzyme was added to a chloroplast preparation that by itself could not reduce triphosphopyridine nucleotide and thereby evolve oxygen (Table 4). These findings again support the conclusion that reduction of triphosphopyridine nucleotide and oxygen evolution are basically separate phenomena. The bacterial pyridine nucleotide reductase cannot bring about a coupling of pyridine nucleotide reduction with oxygen evolution in a bacterial system.

Table 4. PHOTOCHEMICAL OXYGEN EVOLUTION CATALYSED BY PYRIDINE NUCLEOTIDE REDUCTASE FROM *Chromatium*

Min.	Oxygen evolved (μatoms)	Triphosphopyridine nucleotide reduced (μmoles)
5	0·75	0·76
10	1·60	1·40
20	2·78	2·39
30	3·97	3·18

The reaction mixture contained, in a final volume of 3 ml.: washed chloroplast fragments containing 0·3 mgm. chlorophyll; and the following in micromoles: *tris* buffer, *p*H 7·8, 100; $MgCl_2$, 5; ADP, 10; $K_2H^{32}PO_4$, 10; TPN, 6; and a purified pyridine nucleotide reductase preparation from *Chromatium*. The reaction was run at 15° in the light.

Concluding Remarks

The concept of photosynthesis presented now is a further elaboration, in the light of new experimental findings, of that presented earlier[15,8]. It is now possible to envisage, in more detail, the electron transfer reactions from water (OH^-) that result in oxygen evolution. We had first suggested that this may be a dark reaction between water (OH^-) and a cytochrome component peculiar to green plants[15]. Such a reaction, although it appeared thermodynamically possible[15], could not be described in terms of the properties of known cytochrome constituents of green cells[24]. We next suggested that the interaction between OH^- and cytochromes may require an additional input of energy[19], and now it appears that this energy is supplied by an auxiliary light reaction. This auxiliary light reaction is found in green plants but not in photosynthetic bacteria, and explains why photosynthesis is accompanied by evolution of oxygen only in green plants.

The separation of photo-oxidation of water from the photo-phosphorylation reaction is consistent with the view that photosynthesis in green plants involves the participation of more than one light reaction. Warburg *et al.*[25] found in *Chlorella* an enhancement of photosynthesis under red light by the addition of catalytic amounts of blue light and attributed this effect to a photoactivation of a photosynthetic enzyme ('Luminoferment'). The maximum effectiveness of the catalytic light was at 460 mμ. Another light effect, which seems more directly related to our results, was reported by Emerson *et al.*[26], who observed that enhancement of photosynthesis in *Chlorella* under red light was produced by light of shorter wave-length; in their experiments the supplementary light was not catalytic but of an intensity "sufficient to give measurable photosynthesis". Emerson[27] found the maximum effectiveness of the supplementary light in *Chlorella* at 480 mμ, and a lower peak of effectiveness at about 655 mμ, coinciding approximately with the maximum absorption peaks of chlorophyll *b*.

Emerson[27] suggested from these and similar observations with other algæ that, at the long wavelengths of light absorbed only by chlorophyll *a*, full efficiency of photosynthesis depends on the absorption of light of shorter wave-length by an accessory photosynthetic pigment: chlorophyll *b* in *Chlorella*, or phycobilins in other algæ. The supplementary light in this view is not used as a catalyst but is consumed as a substrate.

The enhancement effect of supplementary light has been confirmed by other investigators[28-30]. Of special relevance to our concept is the conclusion of Myers and French[28] that their results favour "the idea that the interaction [of the light absorbed by chlorophyll *a* and *b*] takes place between chemical products of two separate reactions initiated by light" and the report of Govindjee *et al.*[30] that the enhancement effect is associated with the oxygen-liberating mechanism rather than with reduction of carbon dioxide.

That two light reactions, with the participation of water, are involved in the photosynthetic cytochrome system of both green plants and photosynthetic bacteria has been postulated by Hill and Bendall[24]. However, our findings support the conclusion that green plants possess a special photochemical reaction, photo-oxidation of water, that is absent in photosynthetic bacteria. We have not identified the 'pigment' (Fig. 2) that is involved in the photo-oxidation of water. This pigment is more likely to be chlorophyll *b* or an accessory pigment that is found only in higher plants and algæ, rather than chlorophyll *a* (or the closely related bacteriochlorophyll) found in all photosynthetic cells*.

* *Note added in proof.* Additional evidence that oxygen evolution in chloroplasts is catalysed by a photosynthetic pigment different from that involved in the photoreduction of triphosphopyridine nucleotide and photophosphorylation was recently obtained in this Laboratory in experiments with monochromatic light. In the red region of the spectrum, the photo-oxidation of water was most effective around 644 mμ (a maximum absorption peak for chlorophyll *b*), whereas the effectiveness of red light for photoreduction of triphosphopyridine nucleotide and photophosphorylation showed markedly different spectral characteristics (cf. Arnon, D. I., "Photosynthetic Phosphorylation and a Unified Concept of Photosynthesis", Photosynthesis Symp., Fifth Int. Congr. Biochem., Moscow, 1961).

INTRACELLULAR STRUCTURES IN TUMOURS INDUCED BY POLYOMA

By LEON DMOCHOWSKI, CLIFFORD E. GREY, ELIZABETH BERECZKY*
and JULIAN BLICHARSKI†

Section of Virology and Electron Microscopy, University of Texas M. D. Anderson Hospital and Tumour Institute ;
Department of Microbiology, Baylor University College of Medicine, Texas Medical Center, Houston, Texas

CERTAIN animal viruses have been described as forming crystals in the nucleus or cytoplasm of the infected cells (for literature, see ref. 1). Light microscopy of histochemically stained specimens and electron microscopy of similar specimens have indicated the nature and significance of these structures in virus development. The tumour-inducing virus, polyoma, has also been observed to form crystalline-like arrangements of characteristic particles (270 Å.) in the nuclei of mouse embryo cells and of kidneys of hamsters infected with this agent[2]. These particles, however, could not be found in the cells of tumours induced by polyoma in the kidneys of hamsters[2]. An electron microscope study of kidneys of mice, rats, and hamsters infected by polyoma has revealed characteristic particles (270 Å.) in the nuclei of cells, two or three weeks following infection with the virus[3]. Fewer particles have been found in the cells of proliferative lesions in the kidneys of infected animals of the three species, and even smaller numbers in the cells of tumours induced by polyoma in the kidneys of rats and hamsters[4].

In this article the results of extensive electron microscope studies of tumours induced in the kidneys of mice, rats (obtained through the courtesy of Dr. Bernice E. Eddy) and hamsters by tissue culture preparations of polyoma virus will be presented. Only material from kidneys showing gross nodular tumours confirmed by histological diagnosis has been used in the present work. Tissue specimens were fixed in 1 per cent osmium tetroxide buffered with veronal-acetate containing 1 per cent sucrose, dehydrated in ethyl alcohol of graded dilutions, embedded in *n*-butyl methacrylate, and sectioned with glass knives. To enhance the contrast, the sections mounted on grids were floated on a saturated solution of uranyl acetate with the specimen facing down for 30 min.–24 hr. Alternate

Fig. 2. Part of Fig. 1 at higher magnification, showing the particles in the inclusion body of the nucleus. (× 21,000)

Fig. 3. Inclusion in the cytoplasm of a cell of a hamster kidney tumour. (× 5,000)

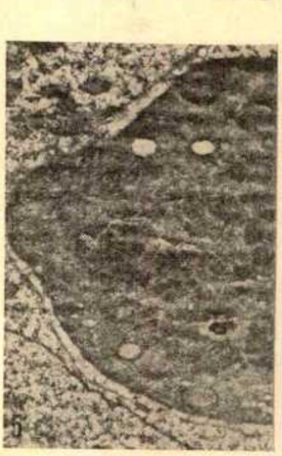
Fig. 4. Cytoplasmic inclusion showing a regular array of particles. (× 22,500)

thin (300 Å.) and thick sections (2μ) were cut. The thick sections were studied by the light microscope, following staining with the Feulgen method. The thin sections were examined in an RCA Type *EMU 3E* electron microscope.

A number of non-specific changes, such as shrinkage of the cells, pyknosis of the nucleus, condensation and vacuolization of the cytoplasm, and alterations in the structure of mitochondria have been observed in the cells of kidney tumours of mice, rats and hamsters. Changes which could be regarded as specific have also been observed in some of the cells in scattered areas of kidney tumours of animals of all three species. Particles, similar to those already described in polyoma-infected cells *in vivo*[5] and *in vitro*[5], have been found scattered throughout the nucleus as shown in Fig. 1, and with more detail in Fig. 2. Vacuolization of the nucleus may also be found (Fig. 1) and the nuclear membrane may be replaced by a tightly packed row of particles. The same nucleus may contain an inclusion body (Fig. 1) filled with characteristic particles in a regular arrangement, as shown at higher magnification in Fig. 2. Occasionally, cells are encountered with enlarged nuclei containing particles scattered at random (Fig. 3) and with cytoplasm showing mitochondria in various stages of degeneration and inclusions, varying from 0·5μ to more than 2μ (Fig. 3). Some of the inclusions are filled with the characteristic particles arranged in regular pattern, as in the largest inclusion shown in the top left-hand corner of Fig. 3, and at higher magnification in Fig. 4. In spite of crystalline-like arrangement of the particles, the structure must not be considered as a crystal until examined by methods such as electron diffraction. In the corresponding thicker (2μ) sections of the same specimen examined by the light microscope, the intranuclear inclusions containing the characteristic particles are positive to Feulgen staining. Cells of tissue cultures of polyoma-infected mouse embryo, examined in the light microscope at various intervals of time after infection, have shown the gradual formation of Feulgen-positive inclusions in the nuclei followed by the appearance of similarly staining inclusions in the cytoplasm[6]. On examination in the electron microscope, the characteristic particles have been found within these inclusions[6]. These inclusions stain as DNA, following acridine orange treatment[7], and the stained inclusions are not removed by digestion with DNA-ase[6]. However, pre-treatment of the cells with pepsin, followed by digestion with DNA-ase, removes the inclusions[6]. This is further indication that the inclusions are of viral nature, as shown in tissues infected by other viruses[7].

Cells have also been observed with most of the cytoplasm filled with strongly osmiophilic material (Fig. 5) in which numerous regular arrays of particles may be seen among mitochondria and vacuoles (Fig. 6). Measurements have been made of 20 particles which appear elliptical in section (Fig. 6). They measure an average of 330 Å. in length and 260 Å. in width. The average distance from centre to centre of the particles is 390 Å. Assuming the particles in the section to be distorted spheres, the diameter of the equivalent circular particles is calculated as 290 Å. In view of the possibility that a peripheral zone of the particles has not been made visible by osmium tetroxide and uranyl acetate, the diameter of the particles, based on the measured centre-to-centre distance and the equivalent circular diameter of the particle, is approximately 390 Å. This measurement of the particle size approximates to that reported for polyoma particles in dried and shadow-cast preparations from infected tissue cultures (440 Å., ref. 8), and in concentrated or partially purified suspensions stained by the negative-contrast method (453 Å.) with potassium phosphotungstate[9].

The particles, which at lower magnifications appear uniformly dense without an apparent membrane or capsid[9], appear to have an internal structure in stained sections examined at higher magnifications (Fig. 7). Similar structure has been seen in the particles present in the sections of cells of infected mouse embryos stained with uranyl nitrate[10]. The structure has been interpreted as reticular and as



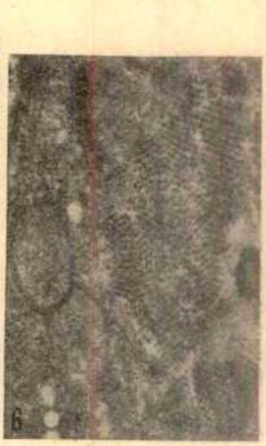


Fig. 5. Cytoplasm of hamster kidney tumour cell showing mitochondria and regular formations of particles. (× 5,000)

Fig. 6. Part of Fig. 5, showing three mitochondria and the characteristic particles. (× 21,000)

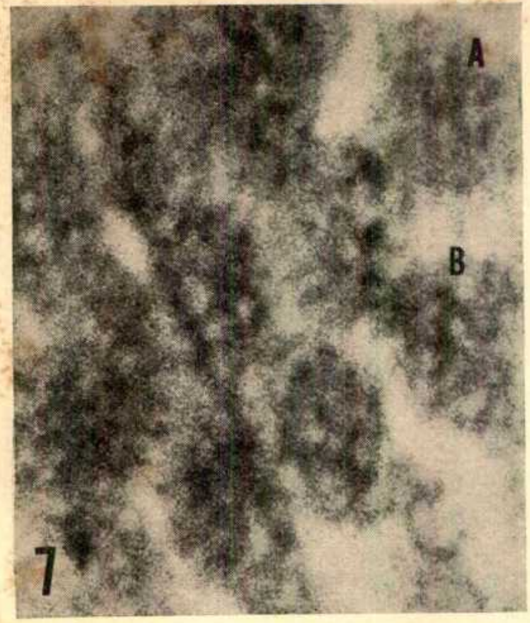

Fig. 7. Some of the particles with outlines of internal structure. (× 540,000)

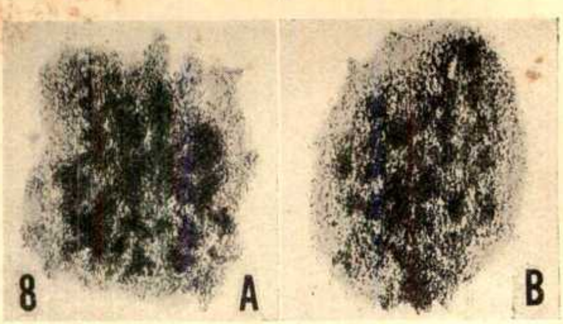

Fig. 8. Schematic drawing of the appearance of two particles shown in Fig. 7

containing an outer coat of lower contrast[10]. A comparison of the appearance of some of the particles (Figs. 7 and 8) with that of the particles stained with potassium phosphotungstate[9] reveals a certain similarity in structure. A detailed description of the structure of the particles present in sections of the kidney tumours will be published.

In conclusion, it may be stated that the characteristic particles in polyoma-infected tissue culture cells and in the kidney cells of infected mice, rats and hamsters are also present in smaller numbers in the cells of kidney tumours of animals of the three species. The observation of particles of similar size and shape in different types of cells infected with polyoma and in tumours induced by this virus in different species gives further support to the identification of these particles as polyoma virus particles.

AN ELECTRON MICROSCOPE STUDY OF THE 'CHLORIDE-SECRETORY CELL' OF *SALMO SALAR* L., WITH REFERENCE TO PLASMA-ELECTROLYTE REGULATION

By DR. LAWRENCE T. THREADGOLD

Department of Zoology, Queen's University, Belfast, Northern Ireland

AND

DR. ARTHUR HILLIER HOUSTON

Department of Zoology, University of Manitoba, Winnipeg, Canada.

THE teleostean kidney is unable to secrete a hypertonic urine. Because of this, the marine teleost must rely on extra-renal electrolyte excretory processes to reduce the salt load incurred in drinking sea-water to replace body-water lost by the process of osmotic dehydration. Smith[1] suggested that the gills might be the site of the extra-renal excretory mechanism, while Keys[2], through the use of a heart–gill preparation, was able to demonstrate the ability of the gill of the eel to transport chloride against a concentration gradient. Afterwards, Keys and Willmer[3] described a type of cell in the gill of this and other species which they suggested might be the site of an active transport system, and tentatively termed it the 'chloride-secretory cell'.

Although similar cells have been described in a variety of marine, euryhaline and anadromous teleosts[4–10,14,15] under varying experimental conditions, their function in electrolyte excretion has not as yet been firmly established. Nevertheless, the adaptive responses observed after transfer between fresh and salt water[5,6], histochemical demonstrations of high cellular chloride content in fish adapted to sea-water[5], correlations between ability to tolerate sea-water and the occurrence of these cells[4,7], and finally the close correlation between their ontogenetical appearance in the migratory salmonids[8-10] and the development of tolerance to sea-water in these species[10-12] provide strong indirect evidence favouring the hypothesis.

On the other hand, several authors have felt that the 'chloride-cell' was not, in fact, associated with electrolyte metabolism. Thus Bevelander[13], on the basis of extensive comparative studies, concluded that the only specialized cells in the branchial epithelium were mucous cells. However, as Copeland[5] has pointed out, at least some of the cell types described by Bevelander as being 'mucous-secretory' had most of the cytological characteristics commonly attributed to 'chloride cells'.

Burden[14] has disclosed a puzzling situation in the course of work on the osmoregulatory ability of hypophysectomized *Fundulus*. Death in fresh-water following the destruction of the pituitary was accompanied by æsthenia, massive decreases in levels of plasma chloride and by atrophy of branchial mucous cells. No obvious variations in 'chloride cell' structure were observed. Copeland[5] has suggested that such cells in *Fundulus* may have dual polarity, excreting electrolytes in sea-water, and functioning in an absorptive role in fresh-water. The situation described by Burden may possibly be accounted for as a failure of the electrolyte absorptive process to cope with increased outward diffusion of electrolytes through surfaces no longer protected by a mucous layer.

Finally, Parry, Holliday and Blaxter[15] have objected to the secretory hypothesis on the grounds that a similar type of cell is found in the pseudobranch in large numbers, where by virtue of blood supply and position, a secretory function was not considered likely; that bilaterally pseudobranchectomized animals were able to survive in sea-water over long periods of time, and that under such conditions no adaptive increases in branchial 'chloride cell' numbers occurred.

In view of the conflicting evidence on this theoretically important aspect of teleostean osmoregulation, we decided to include an electron microscope examination of the branchial epithelium in an investigation of the processes of parr–smolt transformation and adaptation to sea-water in hatchery-reared yearling Atlantic salmon. A part of this work has already been published in *Nature*[16].

Gill structure was examined in parr adapted to fresh-water, and for purposes of comparison in a two-year-old trout (*Salvelinus fontinalis*), in smolt held for 72 hr. in sea-water (400–420 m.moles chloride/litre), and in smolt acclimatized to sea-water for 10 days. Reference to Figs. 1 and 2 of ref. 16 indicates that under these conditions parr displayed some loss of regulatory ability associated with the early stages of parr–smolt transformation, smolt adapted for 72 hr. to sea-water exhibited maximum deviations from the chloride-levels of fresh-water plasma, while fish held in sea-water for 10 days were considered to have completed the process of adaptation.

Gill filaments from the first gill arch were fixed in Dalton's fixative at pH 7·4 and embedded in methacrylate. Sections were cut on a Porter–Blum microtome with a diamond knife and photographed at × 2,000 to × 8,000 on a Phillips *E.M.* 75.

Salvelinus fontinalis (Fig. 1). In this species the 'chloride-secretory cells' were usually columnar, with basally situated ovoid nuclei. There were numerous mitochondria, the majority of which lay between the nucleus and the free pole of the cell. A relatively small number lay basal to the nucleus. Few mitochondria were present in the zone immediately below the apical plasma membrane. Individual mitochondria tended to be elongate with their long axes parallel to that of the cell.

In the mitochondria-free apical zone there were numerous dense micro-vesicles, some of which were either in contact with mitochondria or with the plasma membrane.

Fig. 3. *S. salar*. Smolt. 72 hr. adapted. *S.*, secretory vesicle; *M.V.*, micro-vesicles. (× 3,375)

Fig. 4. *S. salar*. Smolt, 72 hr. adapted. *P.M.*, plasma membrane; *M.V.C.*, micro-vesicles contacting the plasma membrane and discharging. (× 9,000)

Fig. 5. *S. salar*. Smolt. 10-day adapted. (× 3,000)

Fig. 6. *S. salar*. Smolt. 72 hr. adapted. Mitochondria with associated micro-vesicles. (× 45,000)

A variable number of juxta-nuclear Golgi bodies and short lengths of endoplasmic reticulum were also present in the cytoplasm.

The apical plasma membrane was overlain to a variable extent by adjacent electron-dense platelet cells, but in fully developed secretory cells the free membrane was usually the full width of the cell and bulged outward beyond the outer limits of the platelet cells. The membrane of the chloride cell was characterized by the presence of minor undulations, whereas that of the platelet cell usually projected, forming a number of microvilli. External to the cell membrane, there was in most instances a narrow amorphous layer, presumably a secretion product. This suggested a low level of secretory activity in these cells.

Salmo salar (Fig. 2). The 'chloride cells' of the Atlantic salmon parr were in general similar to those described for the trout. Rectangular rather than columnar cells were numerous. Minor differences were found in: (1) a more open cytoplasm with fewer mitochondria, (2) crenated nuclei, and (3) the presence of pale bodies resembling greatly swollen mitochondria. The cells gave the appearance of secretory exhaustion in some instances.

Salmo salar, 72-hr. smolt (Figs. 3, 4 and 6). In the 72-hr. smolt, the 'chloride cells' were either columnar or rectangular. In several features they were clearly distinct from those seen in parr. Mitochondria were often extensively vacuolated and had irregularly arranged cristæ. In some instances the mitochondria had ruptured and tubular cristæ were in the process of being shed into the cytoplasm (Fig. 6).

There was marked evidence of secretory activity with many cells having a mass of amorphous material containing scattered dense granules lying immediately beyond the free apical border. Such cells usually lay in a 'pit' formed by the adjacent platelet cells (Fig. 3).

In cells characterized by a high degree of secretory activity, the apical region was crowded with micro-vesicles of variable size resembling the cristæ shed from the more central mitochondria. With the production of a large secretory mass, the apical region lacked micro-vesicles and the mitochondria-free zone was larger (Fig. 4).

The 'chloride cells' of the 72-hr. smolt were, then, characterized by intense secretory activity of the merocrine type, and apparently related to mitochondrial activity.

Salmo salar, 10-day smolt (Fig. 5). In contrast to the cells just described, those of the 10-day smolt resembled the 'chloride cells' of the parr and trout. They varied from columnar to rectangular in shape, and contained numerous, clearly delineated mitochondria. Few apical vesicles were present and the free surface of the apical cell membrane was reduced. The mass of the secretory product was much less than that seen in the 72-hr. fish, and in many instances no secretory product could be distinguished. In general, a picture of reduced activity characterized the 'chloride cell' of the 10-day smolt.

The 'chloride cell' as described here is comparable to that demonstrated in earlier cytological studies[4–10,14,15] in distribution, overall shape and relative size, in the occurrence of a predominantly basal nucleus, high mitochondrial content, and in the presence of a mitochondria-free apical zone. We have therefore concluded that the type of cell described here represents that investigated in the investigations already cited, and as such is clearly distinct from the typical mucous cell.

The great similarity of these cells in the fresh-water adapted trout, in the parr salmon and in the 10-day smolt is strikingly correlated with chloride-levels in the plasma, which in each instance were apparently regulated within specific limits. It is perhaps notable that among this group some signs of secretory exhaustion were apparent in the cells of the parr, as evidence of an electrolyte imbalance is seen in these fish during the early stages of parr–smolt transformation[16].

In the occurrence of vacuolated mitochondria and an apical zone crowded with micro-vesicles, and in the presence of a large extracellular secretory mass, the cells of the 72-hr. smolt differed markedly from those encountered in animals in dynamic equilibrium with their medium. Such cells gave every indication of heightened secretory activity, which was correlated with sharp increases in electrolyte-levels in the body fluids. The process of secretion appeared to involve formation of large numbers of micro-vesicles by, or in close association with, mitochondria. These vesicles fused with the plasma membrane and were discharged, or released, to form the extracellular secretory mass.

This formation of micro-vesicles in close association with the apical mitochondria and seemingly related to the formation of the extracellular secretory mass is of particular interest in view of Copeland's demonstration by histochemical techniques of a marked concentration of chloride in this area in *Fundulus* adapted to sea-water[5]. It seems reasonable to conclude, then, that the extracellular mass described here is at least in part composed of inorganic electrolytes, possibly excreted in an organic matrix.

The present work corroborates earlier conclusions regarding adaptive changes resulting from transfer of fish from fresh-water into sea-water. Evidence for a secretory function has been presented. In view of Copeland's work already cited[5] and the correlation of enhanced secretory activity and structural changes with maximum increases in electrolyte-levels in plasma, we concluded that this work provides additional support for the hypothesis that the branchial 'chloride-secretory cell' is associated with extra-renal electrolyte excretion in teleosts adapted to the marine environment.

We acknowledge the financial support of the National Research Council of Canada and the Nova Scotia Research Foundation. A full report of this investigation, carried out in the Department of Anatomy and Zoological Laboratory, Dalhousie University, Halifax, Canada, will be published elsewhere.

Satellite Orbit Perturbations in Vector Form

THE first-order perturbation theory of satellite orbits can be formulated simply and elegantly in terms of constants of the unperturbed motion using vector methods. For let the equation of motion be:

$$\ddot{\mathbf{r}} = -\frac{\mu}{r^3}\mathbf{r} + \mathbf{F} \tag{1}$$

where $\mu = GM$ (M = mass of the earth), and $\mathbf{F}$ is a general perturbing force (per unit mass). The energy E and angular momentum $\mathbf{h}$ (both per unit mass) defined as:

$$E = \frac{1}{2}\dot{\mathbf{r}}^2 - \frac{\mu}{r}; \quad \mathbf{h} = \mathbf{r} \times \dot{\mathbf{r}} \tag{2}$$

are constants of the unperturbed motion. Hamilton's integral, which may be written in the form[1]:

$$\mathbf{k} = \frac{\mu}{r}\mathbf{r} + \mathbf{h} \times \dot{\mathbf{r}} \tag{3}$$

provides a further constant of the unperturbed motion under an inverse square law force. Taking scalar products with $\mathbf{h}$ and $\mathbf{r}$, $\mathbf{k}$ is seen to be a vector of length μe lying along the major axis in the direction of apogee. The orbit is over-determined by E, $\mathbf{h}$ and $\mathbf{k}$ which give seven scalar equations.

In the presence of the perturbing force, E, $\mathbf{h}$ and $\mathbf{k}$ are no longer constant, but from (1) satisfy:

$$\begin{aligned} \dot{E} &= \dot{\mathbf{r}} \cdot \mathbf{F} \\ \dot{\mathbf{h}} &= \mathbf{r} \times \mathbf{F} \\ \dot{\mathbf{k}} &= (\mathbf{h} \times \mathbf{F}) + (\mathbf{r} \times \mathbf{F}) \times \dot{\mathbf{r}} \end{aligned} \tag{4}$$

When $\mathbf{r}$, $\dot{\mathbf{r}}$ and $\mathbf{h}$ are taken to refer to the unperturbed orbit, these are the equations of first order in the perturbing force.

It is best to discard two components of $\dot{\mathbf{k}}$ since this has the most complicated equation. Then $\dot{E}$ gives the change in the semi-major axis ($E = -\mu/2a$), $\dot{\mathbf{h}}$ the rotation of the plane of the orbit and the change in eccentricity [$h^2 = \mu a(1-e^2)$], while the rotation of the major axis in the plane is given by the component of $\dot{\mathbf{k}}$ parallel to the minor axis.

The quantities E, $\mathbf{h}$ and $\mathbf{k}$ will give the osculating elements at any time. However, for most purposes the interesting effects are those of period longer than the satellite in its orbit. These are given by the mean rates of change obtained by integrating (4) over a complete orbit, using either the true or the eccentric anomaly, as appropriate, as the independent variable.

The results can often be expressed partly in vector form. For the simple case of a constant force $\mathbf{F}$, corresponding, for example, to radiation pressure on a uniform sphere the orbit of which is entirely in sunlight, the effects are given by:

$$\dot{E} = 0, \; \dot{\mathbf{h}} = \frac{3}{2}\frac{a}{\mu}\mathbf{k} \times \mathbf{F}, \; \dot{\mathbf{k}} = \frac{3}{2}\mathbf{h} \times \mathbf{F} \tag{5}$$

This method has been applied to solar and lunar perturbations and to the effect of radiation pressure when part of the orbit is in darkness. It has also been applied to the second harmonic term in the Earth's gravitational field giving results in agreement with previous work[2].

A treatment essentially in terms of E, $\mathbf{h}$ and $\mathbf{k}$ appears to have been proposed first by Herrick[3], and Musen[4] has applied it to the case of a constant perturbing force giving effectively the results of (5) above.

The Cosmic-Ray Observations of December 4, 1957

A RECENT communication from Legrand and Helary[1] reports an increase in the total component of cosmic radiation at Paris on December 4, 1957. The increase amounted to about 18 per cent and extended over three hours with the maximum occurring at 2245 U.T. A small increase in the nucleonic component at Thule preceded the Paris event by about three hours. Optical and radio data indicate a flare of importance 1 on the western hemisphere of the Sun at 1657 U.T. (ref. 2).

Intensity enhancements at the surface of the Earth are comparatively rare, only eleven cases having been observed. However, these cosmic ray flare events appear to have certain well-defined properties in common. These include correlation in time with a visible or inferred solar flare, a steep integral rigidity spectrum and approximate simultaneity of occurrence at all points on the Earth's surface accessible to the radiation. The steep rigidity spectrum is indicated by the relative rarity of events seen in ground-level neutron monitors as compared to detectors flown in balloons and the small magnitude (or absence) of the increases measured in the meson component compared to the nucleonic enhancements.

Collins and Jelly[3] have reported that ionospheric conditions were normal throughout the period in which the increase in cosmic radiation occurred and have also pointed out that solar activity was low. Since an undisturbed ionosphere at the time of a cosmic-ray flare is an unlikely event, it was thought worth while to examine the intensity of cosmic radiation monitored at the Sulphur Mountain Laboratory at this time. The Laboratory is on a mountain near Banff, Alberta, Canada (lat. 51·2° N., long. 115·6° W.), at 7,500 ft., and houses both neutron and meson monitors. The neutron monitor, consisting of three boron trifluoride counters in a paraffin – lead pile, has a counting-rate of 100,000/hr., and a cubical Geiger counter telescope containing 10 cm. lead

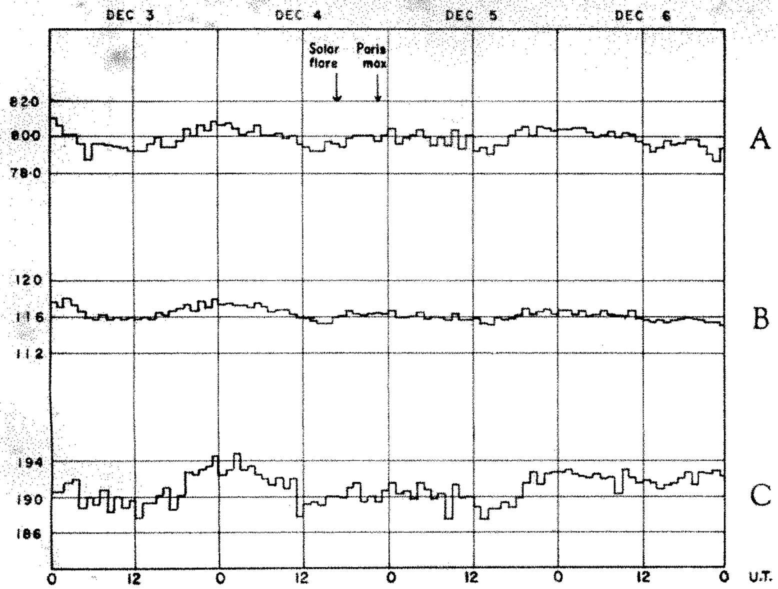

Fig. 1. Rates per hr. of hard, total and nucleonic components : *A*, hard component, *S.F.*, 1,024 ; *B*, total ionizing component, *S.F.*, 2,048 ; *C*, nucleonic component, *S.F.*, 512

measures the intensities of the total ionizing component and the meson component. The counting-rates are respectively 240,000 and 80,000/hr.

The results, corrected for pressure, are plotted in Fig. 1 for the period December 3–6, 1957. It is clear that all three components show no unusual variations during the period of the reported event ; this result is in agreement with other collected data[4] from a large number of stations. Since the data from Paris and Thule are not supported in the records of neighbouring stations, and since the times of the two maxima are well separated from each other and from the time of the optical flare, the events reported are difficult to reconcile with the emerging pattern of the development of cosmic-ray flares. In the absence of corroborative evidence of cosmic ray enhancements or of subsequent Forbush decreases at other stations, and with the negative results of the ionosonde data, it appears reasonable to assume that the reported increase was not associated with an injection of solar protons.

Cosmic Noise Measurements from 1960 η1 at 3·8 Mc./s.

WE wish to report the results of an experiment to measure cosmic noise at 3·8 Mc./s. from an Earth satellite.

Solid-state radiometers, for the measurement of cosmic noise above the ionosphere, have been designed and built at the Defence Research Board Telecommunications Establishment in Ottawa. A single frequency unit, of a type already described[1], was part of the 1960 η1 (*Transit* II*A*) payload and operated satisfactorily for the life of the battery pack.

The satellite telemetry transmitter was turned on and off via a command link, and since command decisions were dependent on the payload battery condition, on some passes there was no telemetry. For the period June 24–27, 1960, the orbital parameters for η1 were as follows: inclination angle $(i) = 66·7°$, apogee altitude, 1,070 km.; perigee altitude, 625 km. The perigee and apogee occurred in the southern and northern hemispheres, respectively. Telemetry stations were located at Washington, D.C.; Fort Myers, Florida; Antigua, British West Indies; Santiago, Chile; Woomera, Australia; and Ottawa, Canada.

The equipment aboard *Transit* II*A* consisted of a superheterodyne receiver with a 40 kc./s. pass-band centred on 3·8 Mc./s., and to reduce errors arising from changes in gain and band-width, the receiver was switched continuously between the antenna and a resistive reference noise source. Temperature tests from $-30°$ C. to $+30°$ C. showed no measurable change in receiver sensitivity. The absolute value of the sensitivity was limited by the efficiency of the antenna since the main payload requirements did not permit the optimum antenna geometry and weight.

For the purposes of calibration, a single-turn terminated loop was permanently attached to each antenna. The loop was calibrated for a known field-strength, and was then used to obtain the input–output characteristics of the radiometer. Antenna pattern measurements indicated negligible departure from that of the ideal magnetic dipole.

For a terminated antenna in thermal equilibrium, the sky temperature is given by :

$$T = \frac{PA}{KB} \qquad (1)$$

where A = effective antenna aperture in m.^{2}; P = power flux in watts m.$^{-2}$ c.s.$^{-1}$; K = Boltzmann's constant; T = temperature in deg. K.; B = band-width c.p.s.; also

$$P = \frac{E^2}{Z} \qquad (2)$$

where Z = the impedance of the medium in ohms ; E = electric field strength of the incident energy in μV./m. for a noise band-width of 40 kc./s.

Table 1 is given in terms of the equivalent linearly polarized free-space field-strength, for a noise band-width of 40 kc./s. in a plane perpendicular to the major axes of the antennæ. To determine P, a correction factor of 1·5 must be made to the value of field strength, E_m, given in Table 1. This correction assumes an omni-directional noise field, whereas the calibrating field was linearly polarized. The expression for P must therefore be rewritten as :

$$P = 1·5\, E_m{}^2/Z \qquad (3)$$

Where the results were not affected by the radiometer sensitivity, the accuracy was dependent on antenna calibration and the stability of the telemetry link. At low signal-levels, the accuracy was limited by the noise signals generated in other apparatus

within the satellite and to a lesser extent by the noise figure of the receiver. From considerations of these factors it is estimated that, for all stations except Woomera, the probable error was +1, −5 db., and for Woomera, the probable error was ±1 db.

Certain features of the results are worthy of further discussion. On the night of June 25, 1960, high-level fluctuating signals were recorded when the satellite was approximately 45° N. latitude in the vicinity of Ottawa, Canada, moving on a north-to-south pass. The fluctuations occurred at the spin-rate of the satellite, which had its spin axis inclined at an angle of approximately 20° to an Earth tangent. At the time of the pass, the f_0F2 at Ottawa, Canada, was 3·5 Mc./s. and it is believed that the fluctuations were due to radiation from the Earth reaching the radiometer. This phenomenon occurred on two successive passes.

Records taken in the northern hemisphere (Ottawa, Canada and Blossom Pt., Maryland) showed no variation in noise power between day and night, whereas those taken at Woomera, Australia, showed considerable variation. Table 1 shows that the local night readings at Woomera were about 2·5 db. higher than the local day readings which were, in turn, 3 db. higher than those for the northern hemisphere.

The one usable record from Santiago, Chile, does not agree with the Woomera recordings even though both stations are at approximately the same latitude. The quality of the Santiago recordings is poor, due to telemetry station difficulties, whereas the Woomera recordings are very good. No ground ionospheric data, which might have resolved this discrepancy, are as yet available from either loc .tion.

The support and co-operation of the Applied Physics Laboratory of the Johns Hopkins University are gratefully acknowledged. Thanks are also due to the National Aeronautics and Space Administration of the United States for recording telemetry data and to the Naval Ordnance Test Station of the U.S. Navy for supplying payload battery power. The contributions of Dr. D. F. Page, of the Defence Research Telecommunications Establishment, in the receiver design and of E. D. R. Shearman, of the Department of Scientific and Industrial Research, Slough, England, in the interpretation of the data are also acknowledged.

GEOPHYSICS

Odd Harmonics of the Earth's Gravitational Field

VARIATIONS in the perigee radius have been observed for three satellites so far. The first of these is *Vanguard I* (1958 beta), which was used by O'Keefe *et al.*[1] in calculating the third and fifth axial harmonics of the Earth's field. The other two are *Transit IB* (1960 gamma) and *Transit IIA* (1960 eta). Nominal values of the pertinent orbit parameters of these three satellites are listed in Table 1. The data

Table 1. ORBITAL PARAMETERS

Satellite	a, Earth radii	e	i, radians	C_p
Vanguard I	1·3615	0·1903	0·5977	−0·00102
Transit IB	1·0871	0·0278	0·8949	−0·00115
Transit II*A*	1·1312	0·0309	1·1639	−0·00026

on *Vanguard* are from O'Keefe *et al.*[1], those on *Transit* I*B* are given by Guier[2], and those on *Transit* II*A* have not been published before.

For our purposes, it is most convenient to express the perigee radius as a function of θ_p, the latitude of perigee, according to:

$$r_p = r_{po} + C_p \sin\theta_p \qquad (1)$$

Values of C_p are listed in Table 1. The probable errors in the values of C_p are believed to be about 7×10^{-5} for *Vanguard* and about 6×10^{-5} for the two *Transits*.

The dependence of C_p upon the orbit parameters is given by:

$$C_p = (J_3/2J_2) - (5J_5/4J_2P^2)\left(1 + \frac{3}{4}e^2\right)\left[\left(1 - \frac{7}{2}f + \frac{21}{8}f^2\right)/\left(1 - \frac{5}{4}f\right)\right] + (35J_7 16J_2P^4)\left(1 + \frac{5}{2}e^2 + \frac{5}{8}e^4\right)\left[\left(1 - \frac{27}{4}f + \frac{99}{8}f^2 - \frac{429}{64}f^3\right) \div \left(1 - \frac{5}{4}f\right)\right] \qquad (2)$$

In this, $f = \sin^2 i$ and $P = a(1 - e^2)$. The terms involving J_3 and J_5 were apparently first derived by O'Keefe *et al.*[1]. The convention that we are using in defining the coefficients J_2, J_3, etc., is specified by writing the gravitational potential as:

$$U = (1/r) - \sum_{n=2}^{\infty} (J_n P_n(\sin\theta)/r^n + 1) \qquad (3)$$

where $P_n(x)$ is the nth Legendre polynomial, normalized to equal unity when $x = 1$. The value of J_2 is approximately $1{\cdot}083 \times 10^{-3}$.

Substituting the data from Table 1, and the estimated errors, into equation 2 yields:

$$J_3 = (-2{\cdot}36 \pm 0{\cdot}14) \times 10^{-6}$$
$$J_5 = (-0{\cdot}19 \pm 0{\cdot}10) \times 10^{-6}$$
$$J_7 = (-0{\cdot}28 \pm 0{\cdot}11) \times 10^{-6}$$

These should be compared with the values:

$$J_3 = (-2{\cdot}4 \pm 0{\cdot}3) \times 10^{-6}$$
$$J_5 = (-0{\cdot}1 \pm 0{\cdot}1) \times 10^{-6}$$

that O'Keefe *et al.* obtained from *Vanguard* I data alone, neglecting J_7.

It is interesting that the value of J_7 obtained here is larger than the value of J_5, although the difference is less than the probable error. It may be that the values of the harmonics beginning with the fifth will be determined principally by the topography, and will thus tend to decrease slowly but erratically with increasing order.

This work was supported by the Department of the Navy, Bureau of Naval Weapons, under Contract *NOrd* 7386.

Measurements of Air Radioactivity in Italy and their Relation to the First Sahara Atomic Explosion

ON the occasion of the French atomic explosion of February 13, 1960, in the Sahara, a control system of radioactivity in the air was set up covering the whole of Italy. The controlling stations of the system were equipped to collect samples of atmospheric dust by means of suction through a filter. The β-activity of the samples was measured 120 hr. after they had been collected.

The stations were established throughout Italy (from north to south) as follows, the heights being in metres:

	Place	Height above sea-level (m.)		Place	Height above sea-level (m.)
1	Pian Rosà	3,488	15	Bari	4
2	Pallanza	212	16	Napoli	2
3	Ispra	251	17	Resina	610
4	Trieste	8	18	Brindisi	8
5	Milano	123	19	Alghero	21
6	Bologna	64	20	Monte Scuro	1,716
7	Genova	364	21	Elmas (Cagliari)	18
8	Monte Cimone	2,173	22	Messina	54
9	Pisa	3	23	Palermo	30
10	Livorno	3	24	Chinisia (Trapani)	74
11	M. Terminillo	1,875	25	Pantelleria	185
12	Casaccia (Rome)	154	26	Cozzo Spadaro (Syracuse)	40
13	Vigna di Valle	270			
14	M. S. Angelo	844			

Two intervals showing increased activity were observed which, although very weak, may be considered as a consequence of the passage of the tropospheric atomic dust cloud originated by the explosion of February 13, 1960, after it had rounded the Earth following an eastward course along the parallels of latitude. The first interval occurred between February 27 and March 2; the second interval between March 7 and March 15.

The two intervals were probably due to the passage of the radioactive dust cloud after it had completed the first passage around the Earth, divided in two parts driven along different itineraries by winds at different altitudes.

In the first interval, higher values were registered, all corresponding to the stations located at greater heights:

Place	Height above sea-level (m.)	Counts
Pian Rosà	3,488	15·00 pc./m.³
Monte Cimone	2,173	8·00 ,,
M. Terminillo	1,875	0·75 ,,
M. Scuro	1,716	1·8 ,,
M. S. Angelo	844	0·6 ,,
Resina	610	0·22 ,,
Vigna di Valle	270	0·8 ,,
Livorno	3	0·15 ,,

During the second interval, stations located on mountains were particularly involved by the passage of the radioactive cloud. In fact, measurements of radioactivity gave the following values:

Place	Height above sea-level (m.)	Counts
Pian Rosà	3,488	2·20 pc./m.³
Monte Cimone	2,173	1·0 ,,
M. Terminillo	1,875	0·5 ,,
M. Scuro	1,716	3·4 ,,
M. S. Angelo	844	0·6 ,,
Vigna di Valle	270	0·24 ,,
Livorno	3	0·12 ,,

The highest activity observed at these stations during the second half of March 1960 was:

Place	Counts
Pian Rosà	0·4 pc./m.^{3}
Monte Cimone	0·2 ,,
M. Terminillo	0·2 ,,
M. Scuro	0·2 ,,
M. S. Angelo	0·2 ,,
Vigna di Valle	0·2 ,,
Livorno	0·09 ,,

The activities registered were always markedly lower than the highest recorded in previous years. In 1958 Naples and Pisa registered the following highest values, namely, 67 pc./m.^{3} and 43 pc./m.^{3} respectively; in 1959 the highest value at Pian Rosà was 22·5 pc./m.^{3}.

PHYSICS

Spin-Lattice Relaxation of Pairs of Chromium Ions in Ruby

The electron paramagnetic resonance spectrum of ruby contains many weak lines as well as those of single chromium ions. It has been established from the dependence of their intensity on the chromium concentration that most of these arise from pairs of ions. An example of the 'pair' spectrum is given in Fig. 1. A complete analysis is not available, but Rimai *et al.* have identified the lines due to nearest-neighbour pairs, and find an antiferromagnetic exchange interaction $JS_1.S_2$, with $J=250$ cm.$^{-1}$, to be present[1]. These pairs are not observed at low temperatures, being then almost all in their singlet ground-state. Most of the lines, however, come from more widely separated ions, and many persist even at 1·3° K. The variation of their intensities with temperature indicates that levels separated from the ground-state by 0–15 cm.$^{-1}$ are present.

The spin-lattice relaxation of the ion-pairs in a crystal containing 0·12 per cent chromium has been measured from the recovery after saturation of some of the more prominent lines in the X-band 'pair' spectrum. The recovery was usually adequately described by a single time-constant. The measured times are shown in Figs. 2(*A*–*E*). In part of the range the times vary more or less inversely as the temperature T, suggesting relaxation through single phonons with energies less than kT. At higher temperatures the relaxation times vary more rapidly, presumably as multiple-phonon processes assume importance. At the lowest temperatures the relaxation of some of the lines becomes independent of temperature. This may be evidence that phonons with energies equivalent to several deg. K. are concerned in the relaxation: a variation with $\{1-\exp(-E/kT)\}$ is to be expected in the relaxation between two excited levels if this takes place through single phonon processes to and from a third level the energy of which is lower by an amount E. Relaxation via an upper level, with times varying as $\{\exp(E/kT)-1\}$, has been observed in cerium[2]. Further experiments are necessary to decide between this explanation and the alternative that at the lowest temperatures the measurements were merely of the rate of transfer of spin energy from the pairs to the single ions by temperature-independent spin-spin relaxation.

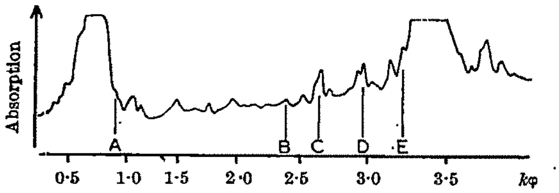

Fig. 1. Paramagnetic resonance of chromium pairs in ruby (room temperature spectrum, radio-frequency 9,400 Mc./s., magnetic field parallel to crystal axis). Single-ion lines occur at fields of 750 and 3,350 φ

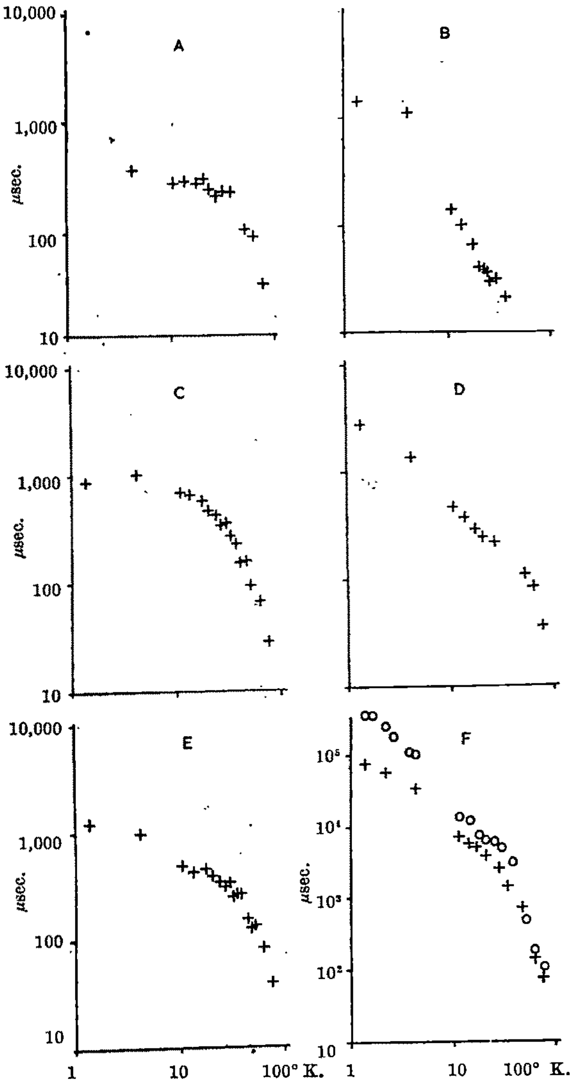

Fig. 2. Relaxation in a ruby containing 0·12 per cent chromium. *A*–*E*, Relaxation times measured from 'pair' lines *A*–*E* in Fig. 1; *F*, relaxation times of 750-φ line (circles) and of 3350-φ line (crosses) in single-ion spectrum

The relaxation of two of the single-ion lines has also been examined. The relaxation times were measured from the last part of the recovery, to reduce the effects of spin-spin relaxation[3]. The measured times are shown in Fig. 2*F*.

The relaxation of the pairs is 10–300 times faster than that of the single ions in the same crystal. Fast relaxation is to be expected in pairs of ions with spins greater than ½ if strong exchange interactions are present, as transitions involving energies of the order of the exchange energy are possible[3]. Since this energy may be much greater than that of the single-ion transitions, far more lattice modes may be available to bring about the relaxation of a pair than of a single ion. Possible means whereby the lattice vibrations might induce the transitions include the 'Van Vleck' modulation of the electric fields of diamagnetic neighbours, and also modulation of anisotropic exchange interactions, or of isotropic interactions in the presence of some other anisotropy.

The relaxation of the pairs seems sufficiently rapid to account for much of the relaxation of the single ions. For example, let us assume that the pairs relax on the average 100 times more rapidly than the single ions, and that each single-ion line is effectively coupled by spin-spin processes to ten 'pair' lines. Then if the populations of the 'pair' levels are 0·1 per cent of those of the single-ion levels, we find that the energy reaching the lattice from the pairs accounts for the entire loss from the single ions. This may possibly provide an explanation of the concentration-dependent relaxation times commonly observed in ruby[4].

A more detailed account of this work will be published on its completion. I should like to thank Dr. R. J. Elliott and Prof. J. H. Van Vleck for helpful discussions, and Drs. C. B. P. Finn, R. Orbach and W. P. Wolf for letting me have details of their work in advance of publication.

Note added in proof. Since this was written, an analysis of the 'pair' spectrum has been reported (Weber, M. J., Rimai, L., Statz, H., and de Mars, G., *Bull. Amer. Phys. Soc.*, 6, 141; 1961). The authors present indirect evidence for fast 'pair' relaxation, and point out the possible connexion with concentration-dependent single-ion times.

'Memory' of Initial Remanent Magnetization and Number of Repeating of Heat Treatments in Low-temperature Behaviour of Hæmatite

It has recently been reported that the remanent magnetization of hæmatite (αFe_2O_3) indicates a marked thermal hysteresis phenomenon during a cooling–heating cycle to interpose the transition temperature of about 250° K., where the rotation of spin axis occurs: on cooling below 250° K. and then re-heating to room temperature, the direction of the remanent magnetization is still memorized in the specimen, although its intensity does not recover its original value before the cooling–heating cycle[1]. A satisfactory explanation of such behaviour has not so far been given, though much work has been carried out on this problem[2,3]. In this communication, new information on the 'memory' phenomenon will be reported.

The thermo-remanent magnetization and the isothermal remanent magnetization of the synthetic hæmatite powders were subjected to the repeated cooling–heating cycles between liquid nitrogen temperature and room temperature. In both cases, change in the intensity of remanent magnetization after the temperature cycling was measured by an astatic magnetometer at the room temperature. Recoveries relative to the initial remanent magnetizations, which were acquired in various magnetic fields, after the repeated cooling–heating cycles, are shown in Fig. 1 in reference to the numbers of cycle, where the thermo-remanent magnetization is indicated by circles and the isothermal remanent magnetization by dots.

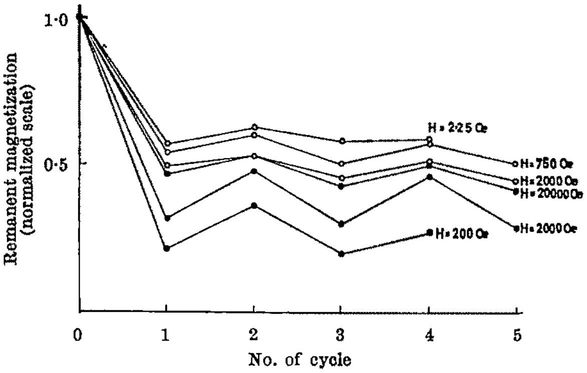

Fig. 1. Remanent magnetization of synthetic hæmatite powders at room temperature after the repeated cooling–heating cycles. ○, Thermo-remanent magnetization; ●, isothermal remanent magnetization

It is found in the figure that the recovery of the intensity of remanent magnetizations after the first cycle is closely dependent on the process leading to the remanent magnetization. The rate of recovery is generally large in the case of thermo-remanent magnetization compared with isothermal remanent magnetization. It is also found that in the case of thermo-remanent magnetization the larger the applied magnetic field, the smaller the rate of recovery, while in the case of isothermal remanent magnetization the relation between the rate of recovery and the applied field is reversed. In the very strong field, the rate of recovery in both cases is confused.

Another interesting fact obtained in this work is that the intensity of remanent magnetization changes systematically in response to the number of cycles for the repeated temperature cycling. As seen in Fig. 1, the marked decrease in the first cycle is followed by a 'zig-zag' change for the repeated cycling, in a series of experiments the intensity of remanent magnetization corresponding to any even number of cycles ($2n$th cycle) being generally larger than that corresponding to the consecutive odd number of cycles ($2n \pm 1$ th cycle). This 'zig-zag' phenomenon is also dependent on the process leading to the remanent magnetization. A relative amplitude of the 'zig-zag' to the initial remanent magnetization is largest in the isothermal remanent magnetization produced by a weak magnetic field and smallest in the thermo-remanent magnetization produced by a weak magnetic field. The amplitude amounts to about 15 per cent of the initial remanent magnetization in the former case, and only a few per cent in the latter case. It is also confirmed from a similar experiment shown in Fig. 2 that this 'zig-zag' phenomenon is conserved for a large number of cooling–heating cycles, though the amplitude decreases almost exponentially.

Considering that a similar phenomenon is observed in the hæmatite powder synthesized from iron (Johnson Matthey and Co., Ltd.), which is believed to be pure, this 'zig-zag' phenomenon may not be attribut-

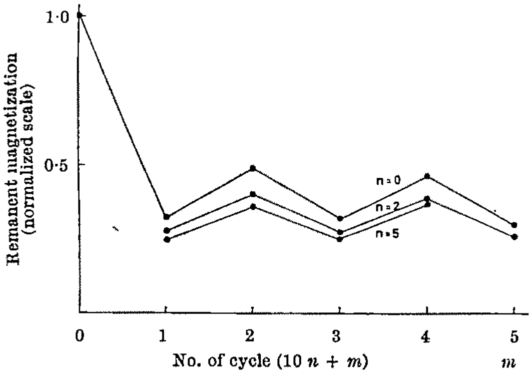

Fig. 2. Systematic change in the isothermal remanent magnetization of synthetic hæmatite powders at room temperature with large numbers of cooling–heating cycles (H = 2,000 oersteds)

able to any special characteristic of the hæmatite specimen. It has been confirmed, too, that the spatial orientation of the hæmatite specimen, relative to the geomagnetic field during the cooling–heating cycles, has no appreciable effect on the 'zig-zag' phenomenon. In view of these results, it may be concluded that this 'zig-zag' phenomenon is essentially related to a parasitic ferromagnetism of hæmatite.

A unified mechanism, through which the combined phenomena, namely, the memory and the 'zig-zag'. of the remanent magnetization of hæmatite at low transition temperature can be interpreted simultaneously, may be required in future work.

The Use of the Term 'Flux'

Recent suggestions[1] for the adoption of a unit of neutron intensity in reactor physics and technology provide an opportunity to raise the issue of non-ambiguity. In the physical sciences, the term 'flux density' has been used since the earliest days to denote units of the relevant quantity per unit area traversed normally per unit time. The term 'flux', then, describes the product 'flux density × area'. Apparently owing to the isolation of nuclear physics during the period 1939–45, the practice seems to have become established in certain branches of this subject and its associated technologies of using the term 'flux' as a short hand for 'flux density'. This ambiguous use tends to deprive both terms of their original significance, and has led to considerable confusion.

The ambiguity is quite unnecessary and its continuance is surely most undesirable. We should like to propose, therefore, that any unit such as the chad, whatever its magnitude, should be defined as a unit of flux density, its dimensions being $NL^{-2}T^{-1}$.

CRYSTALLOGRAPHY

Structure of Vapour-deposited Carbon

Although considerable information is available in the published literature on the effect of temperature and pressure of deposition on the microstructure and density of vapour-deposited carbon, only little has been reported on the pyrolytic graphite formed under these conditions from the crystallographic point of view. The purpose of this communication is to present X-ray results obtained in these laboratories from analysis of a series of experimental deposits produced over a range of high temperatures at a pressure of 50 mm. mercury. The perfection of three-dimensional crystallinity exhibited in some specimens produced at moderate deposition temperatures at this pressure is, to our knowledge, a new observation.

Pyrolytic graphite is deposited on a substrate by passing a vapour source of carbonaceous material at reduced pressure and raised temperature over a heated surface. The pyrolytic graphite produced in this way exhibits stacking such that the atomic basal planes are parallel, as in natural graphite, but the atomic layers are randomly oriented to each other. This arrangement destroys the periodic repetition of atom positions in the c axial direction, and produces greatly different electrical and thermal conductivities in the directions normal and parallel to the substrate surface.

X-ray patterns of pyrolytic graphite specimens produced in these laboratories, as well as a commercial graphite and a commercial pyrolytic graphite sample, were obtained with a 114·59-mm. Debye–Scherrer powder camera using copper K_{α} radiation. The details of the X-ray analyses of these samples are shown in Table 1 and Fig. 1. These results indicate that the

NORMAL GRAPHITE
VAPOR DEPOSITED AT 1900° C
VAPOR DEPOSITED AT 2200° C
VAPOR DEPOSITED AT 2300° C
VAPOR DEPOSITED AT 1700° C

Fig. 1. X-ray photographs of graphite

Table 1. PREPARATION DATA AND X-RAY EXAMINATION OF GRAPHITE

Temperature of deposition (deg. C.)	X-ray data	Method of deposition
2,300	Some disorder in the *c* direction	Resistance furnace 50 mm. mercury
2,200	Some disorder in the *c* direction	Resistance furnace pressure unknown commercial source
1,900	All (*hkl*) reflexions present	Induction furnace 50 mm. mercury
1,700	No (*hkl*) reflexions, lack of three dimensional structure	Resistance furnace 50 mm. mercury
—	Well-defined (*hkl*) reflexions	Commercial graphite substrate material

X-ray diffraction powder patterns obtained differ significantly from results of previously reported investigations. The published literature indicates that as the temperature of deposition decreases, there is a loss of the three-dimensional structure as evidenced by the increasing absence of (*hkl*) reflexions. From Fig. 1, it can be seen that at a deposition temperature of 1,700° C. and pressure of 50 mm. mercury, all the (*hkl*) reflexions are absent. At 1,900° C. there seems to be good atomic alignment in the *c* direction. At higher temperatures of 2,200° C. and 2,300° C., the ordering of the structure again becomes less perfect.

These preliminary observations indicate that high temperature *per se* is not the controlling factor for producing an ordered three-dimensional structure of pyrolytic graphite. The variables of pressure, rate of gas-flow, and method of heating the carbon-bearing gas phase, all have a marked influence on the resultant density and structure. Further investigations are now in progress to determine the effect of these variables on the structure and properties of vapour-deposited material.

CHEMISTRY

Flash Photolysis of Ferrous Sulphate Solutions

KEEN has recently[1] described the kinetics of oxidation of Fe(II) by the transient species produced when a 2-μsec. pulse of 4-MeV. electrons is absorbed by an aqueous solution. We have observed that a similar oxidation occurs in the flash photolysis of ferrous sulphate solutions.

Using a quartz reaction vessel about 1 cm. in diameter and 20 cm. long and a parallel quartz discharge lamp (4 μf., 15 kV.), we find that about 5 μ*M* Fe(III) is produced for each flash irradiation of aerated ferrous sulphate solutions (10^{-4} *M*–5×10^{-3} *M* in 0·01 *N* sulphuric acid) as measured by its absorption at 3130 Å. The effective wave-length in the flash must be less than 2000 Å. since the solutions do not absorb appreciably above this wave-length, and furthermore we find that the oxidation is prevented when an atmosphere of nitrous oxide surrounds the flash tube and reaction vessel.

The oxidation does not result from the direct absorption by Fe(II), since the extent of oxidation is almost independent of concentrations from 10^{-4}–10^{-3} *M*, although it increases at higher, and falls off at lower, concentrations. Moreover, the oxidation occurs in a time-period well outside that of the flash. We have followed the reaction using the usual photomultiplier-oscilloscope technique and find that at low concentrations there are three distinct stages. Fig. 1, using a time-scale of 40 msec. per division, shows a rapid initial absorption followed by a slower one. With a time-scale of 1 msec. per division the rapid rise is resolved into the curve of Fig. 2. The third stage follows these and extends over seconds at 10^{-4} *M* Fe(II).

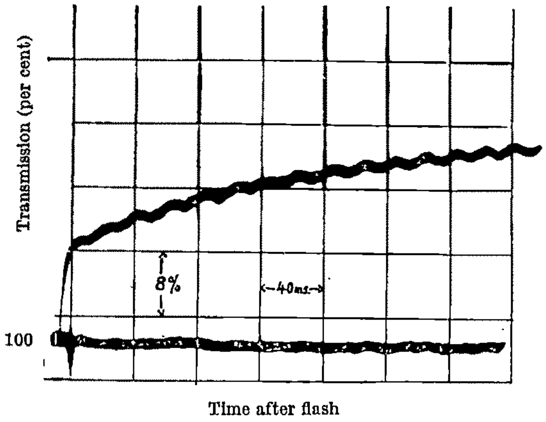

Fig. 1. Optical absorption of 10^{-4} *M* ferrous sulphate in 0·01 *N* sulphuric acid at 313 mμ after illumination with a 40-μsec. flash. Time-scale, 40 msec. per division

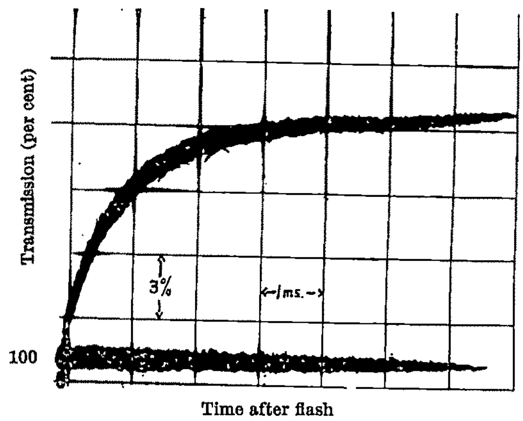

Fig. 2. As Fig. 1. Time-scale, 1 msec. per division

A precise kinetic analysis of each of these processes is difficult since they overlap to some extent, but each appears to be first order in the species which oxidizes Fe(II). The slowest step is also first order in Fe(II) concentration (Table 1) and has a second-order rate constant which is exactly that for the $Fe^{2+} + H_2O_2$ reaction[2] (60 ± 2 m.$^{-1}$ l.sec.$^{-1}$). The second stage is kinetically similar to a second-order constant 6×10^4 m.$^{-1}$ l.sec.$^{-1}$, but the first stage is apparently zero order in Fe(II) concentration (Table 1).

The similarity of rate constants suggests that the species oxidizing Fe(II) in the final step is hydrogen peroxide. The other two are more difficult to identify

Table 1. FIRST-ORDER RATE CONSTANTS FOR THE THREE STAGES OF OXIDATION OF FE(II) IN AERATED 0·01 *N* SULPHURIC ACID

Fe(II) m*M*	k_1 sec.$^{-1}$	k_2 sec.$^{-1}$	k_3 sec.$^{-1}$
0·10	370	6·0	—
0·20	380	12·3	—
2·0	—	—	0·120
5·0	—	—	0·310

but presumably one of them, possibly HO_2, is a precursor to the hydrogen peroxide, for example, by the reaction:

$$Fe^{2+} + HO_2 \rightarrow Fe^{3+} + HO_2^-$$

If, as we suggest, absorption by Fe(II) is not the primary reaction, the species oxidizing Fe(II) must arise from absorption by one or more of water, sulphuric acid and oxygen. The effective wavelength cannot be much below 1850 Å. because of absorption by the quartz, and if we ignore oxygen for the moment, the absorption coefficients for water[3] and ions from sulphuric acid[4] indicate that about 60 per cent of 1850 Å. light will be absorbed by water in 0·01 *N* sulphuric acid solution. Water is known to be photolysed[5]:

$$H_2O \xrightarrow{h\nu} H + OH$$

and the sulphate ion may ultimately give the same products:

$$SO_4^{=} + H_2O \rightarrow SO_4^{-} + H + OH^- \xrightarrow{H_2O} HSO_4^- + OH + H + OH^-$$

The hydrogen atom with oxygen will rapidly give water, so that we might expect HO and HO_2 to be the oxidizing entities.

However, on this basis the extent of the final slow step would be equal to the sum of the two preceding fast ones, whereas we find it is somewhat less than this. This may indicate that other species, possibly resulting from absorption by oxygen, are responsible for at least some of the oxidation. We would also expect both fast steps to be first order in Fe(II) concentration. The zero order found for the first stage could arise from the relatively slow formation[6] of the absorbing species $Fe^{3+}SO_4^{=}$ but we found the presence of 0·01 *N* sodium sulphate to have no effect on this rate.

Subsequent work with perchlorates (to be published, J. H. B.) shows that in the absence of oxygen the final slow step is absent and that the rate constant of the second step is unaffected. This suggests that the second step with a rate constant 6×10^4 m.$^{-1}$ l.sec.$^{-1}$ is:

$$Fe^{2+} + HO \rightarrow Fe^{3+} + OH^-$$

If this is the case it would imply that the reaction:

$$HO + HO \rightarrow H_2O_2$$

must have a rate constant $\ngtr 10^7$ in order for it not to compete with the Fe^{2+} reaction.

Use of Flash Photolysis to initiate Detonation in Gaseous Mixtures

Thrush[1] has reported on the apparent heterogeneity of initiation of reaction in gaseous mixtures of acetylene and oxygen sensitized by nitrogen dioxide, when flash photolysis was used to produce a region of homogeneous chemical reaction. The techniques of using flash photolysis to initiate explosions of hydrocarbon–oxygen–nitrogen dioxide systems are well known[2,3]. This apparent heterogeneity has been explained by the appearance of detonation waves over very small distances. It occurred to me that flash photolysis might be used to initiate detonation waves of certain geometries in a current detonation and shock-wave shaping programme in this laboratory.

The results of one-dimensional experimentation are reported here.

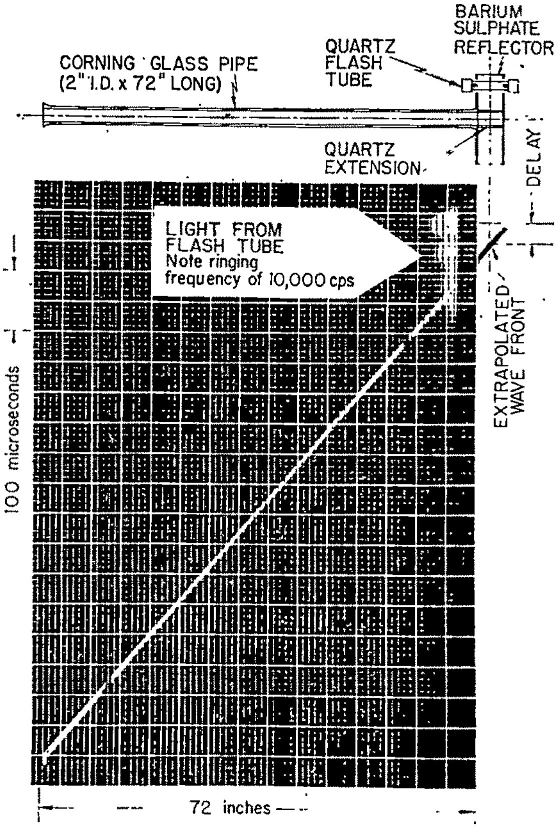

Fig. 1

Fig. 1 gives details of the apparatus employed together with a typical smear photographic record of the detonation wave. A 4-in. length quartz extension was fitted to a 6-ft. length of 2-in. internal diameter Corning glass pipe. The extension was provided with an ultra-violet reflector of barium sulphate and a simple linear quartz discharge tube produced the photolytic flash. The pipe was then oriented with respect to a longitudinal slit so that the detonation wave could be recorded on a simple revolving drum camera. The discharge through the flash lamp in an argon atmosphere was approximately 2,700 joules at 9 kV. The lamp was fired by reducing the pressure of the argon. It will be seen in the smear photograph that the light from the discharge tube was recorded as well as the luminous detonation wave. This gave

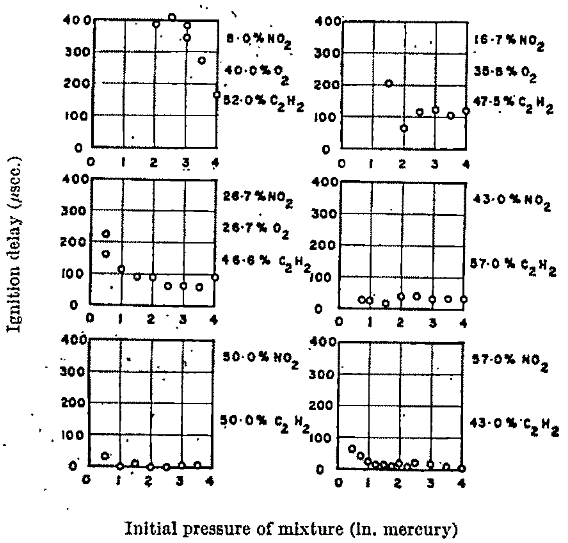

Fig. 2

a measure of the time of the flash with respect to the occurrence of detonation. The time between the first peak in the flash and the occurrence of the extrapolated detonation wave, at the centre of the quartz extension, was arbitrarily taken as the ignition delay.

This ignition delay has been the subject of the early experimentation, and Fig. 2 presents the range of the examination. The variables were the mixture composition and the initial pressure of the mixture. The effect of increasing concentration of nitrogen dioxide was to reduce the ignition delay, while increasing initial pressure had less effect.

In conclusion, stable detonation has been initiated in acetylene, oxygen, nitrogen dioxide mixtures immediately in space, but with a time-delay dependent on mixture composition and initial pressure of the mixture.

Radiolysis of Carbon Tetrachloride in the Presence of Oxygen

Carbon tetrachloride containing oxygen from the air is very often used as a solvent for the isolation of radioisotopes, as a radiation–polymerization inhibitor, and as a basic material in chemical dosimetry and in sulphur-35 production as well. Its radiolysis is very significant in all these cases.

When carbon tetrachloride in the presence of oxygen is irradiated, free chlorine, phosgene and hexachlorethane are liberated. This system was investigated by Kailan *et al.*[1–3] many years ago, but their results cannot be interpreted quantitatively. Several authors recently investigated this system in the absence of oxygen and the results obtained by them differ greatly from each other[4–8]. It is impossible to deduce from them the mechanism of radiolysis of carbon tetrachloride in the presence of oxygen. Only Durup[9] occupied himself with the influence of oxygen on radiolysis of carbon tetrachloride, but hitherto nobody has measured the production of phosgene.

We have measured the production of chlorine in carbon tetrachloride irradiated in the presence of oxygen with soft X-rays[10]. Now we present further details about the origin of chlorine and phosgene produced by γ-radiation.

Irradiation was carried out at 22° C. using a cobalt-60 source with a dose-rate of $2·5 \times 10^{16}$ eV./min./ml. carbon tetrachloride. Carbon tetrachloride used was a product of Lachema, grade p.a., dry, without further purification. For the measurement of chlorine the spectrophotometer at wave-length 335 mµ was applied. Phosgene was estimated partly by the colorimetric phenylhydrazine modified method, partly by the acidimetric titration. Doses from a cobalt-60 source were measured by the Fricke ferrous sulphate dosimeter ($G_{Fe^{3+}} = 15·6$) and a correction on different electron densities was applied.

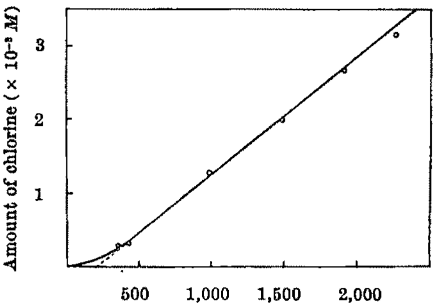

Fig. 1

From Fig. 1 we see that the initial production of chlorine is exponential (induction period up to 140 min. with our conditions) and then linear up to very high doses with $G_{Cl_2} = 3·6 \pm 0·3$. These results can be explained by the following reactions:

$$CCl_4 \xrightarrow{k_1 I\ CCl_4} CCl_3 + Cl$$

$$Cl + CCl_4 \xrightarrow{k_2} Cl_2 + CCl_3$$

since the calculated concentration of chlorine has the same graphical shape as the experimental curve, then:

$$[Cl_2] = k_1 I t - \frac{k_1 I}{k_2\,[CCl_4]} + \frac{k_1 I\, e^{-k_2 [CCl_4] t}}{k_2\,[CCl_4]} \qquad (1)$$

Through the analysis of the experimental curve from Fig. 1 by the help of equation (1) we then obtain the rate-constants $k_1 I$ and k_2:

$$k_1 I = 2·5 \times 10^{-8}\ \text{mole-litre}^{-1}\ \text{sec.}^{-1}$$
$$k_2 = 1·1 \times 10^{-5}\ \text{mole-litre}^{-1}\ \text{sec.}^{-1}$$

The G-value of chlorine is higher than in our earlier work[10], because there we used 30-kV. X-rays and the doses were applied in the induction period range.

In Fig. 2 the amount of phosgene is plotted against the radiation dose. We see that the production of phosgene is linear up to the dose 5×10^{19} eV./ml. with the G-value of phosgene $= 12·1 \pm 1·0$. The situation is rather complicated at high doses and the shape is non-linear. The production of phosgene can be explained by the reactions:

$$CCl_3 + O_2 \xrightarrow{k_3} COCl + Cl_2O$$

$$COCl + CCl_4 \xrightarrow{k_4} COCl_2 + CCl_3$$

$$2\,CCl_3 \xrightarrow{k_5} C_2Cl_6$$

according to which the concentration of phosgene is proportional to the dose:

$$[COCl_2] = \frac{2\,k_1 k_3}{k_5}[O_2]\,I^{1/2}t \qquad (2)$$

We are working now on confirming equation (2).

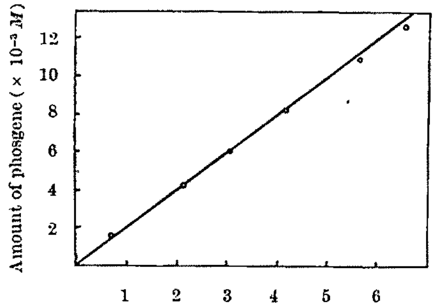

Fig. 2

Both G_{Cl_2} and G_{COCl_2} obtained here are comparable with the results of Durup[9] and other authors[5,7] where $G_{Cl^\cdot} = 3\cdot9$ and $G_{-O_2} = 8\cdot3 \pm 1\cdot0$. According to our reactions the value of $G_{Cl^\cdot}$ must be the same as G_{Cl_2} and approximately $G_{-O_2} \doteq G_{COCl_2}$. For the time being, we have no explanation for the difference existing between G_{Cl_2} in the absence of oxygen[5-8] and in the presence of oxygen.

We are indebted to Prof. Běhounek for his interest and to our co-workers from the Dosimetric Department of the Nuclear Research Institute for their help.

Liquid Chromatographic Separations using Rubber as the Stationary Phase

In a previous communication[1] it was reported that certain polymers could be separated from mineral oil by a liquid chromatographic method. n-Heptane was used as the mobile phase and small pieces of thin vulcanized natural latex as the stationary phase. It has now been found that compounds of lower molecular weight can also be separated by this method.

The use of rubber for the separation of compounds of low molecular weight was first described by Boldingh[2]; he found it advantageous first to swell the rubber with a different solvent from that used as the mobile phase. The use of a cross-linked dextran ('Sephadex') for separating compounds in aqueous solution has been described by Gelotte[3]. Vaughan[4] has mentioned the possibility of using cross-linked polystyrene beads for this purpose.

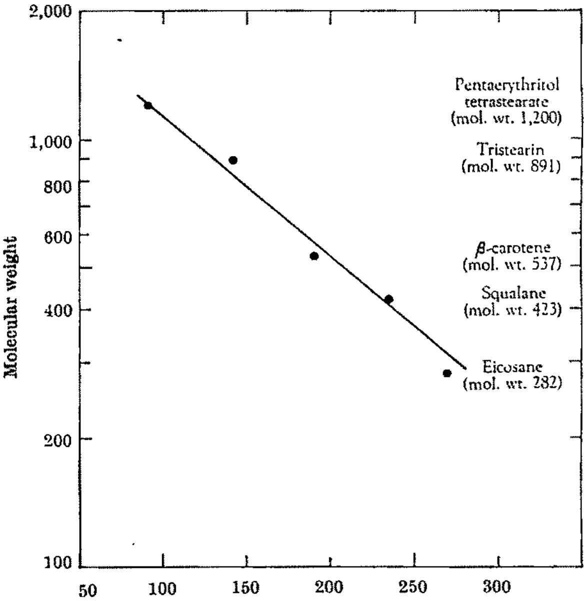

Fig. 1. Effect of molecular weight on corrected retention volume

Boldingh used a fraction of a commercially available rubber powder; but it has been found in these laboratories that columns packed with a similar rubber powder were less efficient than those packed with pieces of surgeons' finger-cots. A column 25 mm.

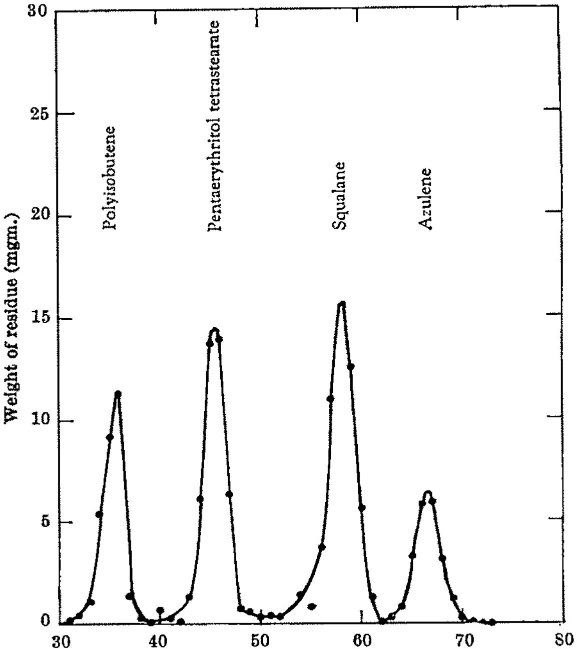

Fig. 2. Separation of a mixture of polyisobutene (mol. wt., 18,000), pentaerythritol tetrastearate (mol. wt., 1,200), squalene (mol. wt., 423) and azulene (mol. wt., 128)

in diameter surrounded by a water jacket at 30° C. was used, packed tightly to a length of 107 cm. with pieces of surgeons' finger-cots passing an 8 mesh B.S. sieve when dry, and retained on a 325 mesh B.S. sieve when swollen with toluene.

The substance (50–100 mgm.) under study was dissolved in 5 ml. of toluene and placed on top of the packing. After the solution had passed into the packing, further toluene was added and the flow-rate adjusted to about 15 ml. an hour. Fractions of 10 ml. were collected in which the solute was determined either by evaporating the toluene and weighing the residue, or colorimetrically in the case of β-carotene and azulene. A graph of corrected retention volume (the retention volume of the elution curve maximum less the void volume of the column) against logarithm molecular weight is shown in Fig. 1. It will be seen that the relationship is approximately linear. An attempt to determine the retention volume of 'Carbowax' polyethylene glycol 1540 was unsuccessful, a very flat elution curve being obtained.

The column used for the above work gave peaks with irregular trailing edges due to the uneven flow of the mobile phase through the column. A second column, 15 mm. in diameter and 207 cm. long, was prepared. Also, the rubber packing was reduced in size so that it passed through a 60 mesh B.S. sieve; and it was packed loosely by allowing it to settle under its own weight. This column gave symmetric elution curves, and the linear relationship between corrected retention volume and logarithm of the molecular weight was again obtained.

The elution curve obtained in the latter column for a mixture of 23·1 mgm. of poly*iso*butene (average molecular weight 18,000), 46·4 mgm. of pentaerythritol tetrastearate, 50·6 mgm. of squalane and 20·8 mgm. of azulene is shown in Fig. 2. Fractions of 5 ml. were collected; recoveries of the compounds ranged from 91 to 103 per cent.

BIOPHYSICS

Influence of Atmospheric Oxidation on Supercontraction of Wool Fibres reduced with Thioglycollic Acid

The rate of supercontraction of a keratin fibre is progressively enhanced by chemical treatment which results in the breakdown of the disulphide cross-linkages in the fibre. The maximum supercontraction value is, however, not greatly affected by such treatment[1]. Fibres, in which the disulphide cross-linkages have been reduced with thioglycollic acid, contain a high percentage of sulphydryl groups[2]. These sulphydryl groups tend to undergo atmospheric oxidation, which causes the formation of new —S—S— cross-linkages[3], a reaction which can be prevented by blocking the reactive —SH groups. The question arises as to what the effect of such oxidative changes will be on the supercontraction of reduced fibres.

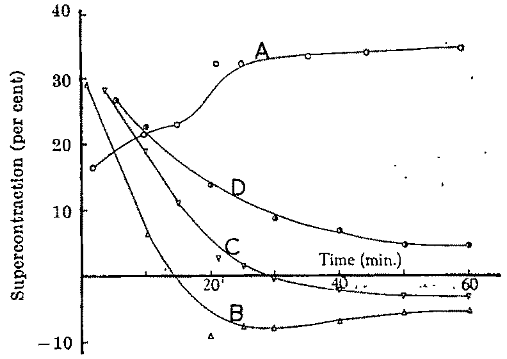

Fig. 1. Fibre reduced for 3 hr. in 1 *M* thioglycollic acid. *A*, normal untreated fibre; *B*, immediately after reduction; *C*, 8 days after reduction; *D*, 20 days after reduction

The microscopic technique, described by Haly and Griffith[4], was employed for obtaining the kinetic supercontraction curves of the fibres.

A sample from a fleece of 64's Merino wool was washed successively in petroleum ether, 0·1 per cent aqueous solution of 'Lissapol *N*' (Imperial Chemical Industries, Ltd.), water, ethanol and finally ether, all at room temperature, and then dried in a stream of cold air.

Sections of about 1·5 cm. were cut from the root end of a fibre. Snippets, 0·5–1 cm. in length, from both ends of this section, were supercontracted in 7·82 *M* lithium bromide solution at 90° C. If both snippets showed the same supercontraction behaviour, it was assumed that the fibre section was homogeneous along its length. The fibre section was then treated for 3 or 7 hr. at 35° C. with a 1 *M* solution of thioglycollic acid in *p*H 5·2 acetate buffer[5]. After the required reaction-time had expired, the fibre was washed well in oxygen-free distilled water on a sintered glass filter. It was then dried rapidly in a stream of air at 40° C. When dry, a snippet was cut off and supercontracted. The rest of the reduced fibre was stored in the absence of direct light. At various

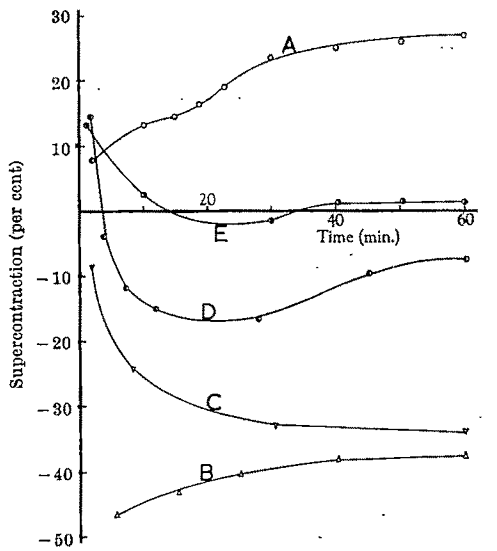

Fig. 2. Fibre reduced for 7 hr. in 1 *M* thioglycollic acid. *A*, normal untreated fibre; *B*, immediately after reduction; *C*, 4 days after reduction; *D*, 10 days after reduction; *E*, 26 days after reduction

time-intervals, snippets were cut off and supercontracted.

The results are shown in Figs. 1 and 2. It is obvious that reduction of 3 hr. is sufficient in the case of Merino wool to break the fibre down to such an extent that partial solution takes place in the contractant. This partial solution could, in fact, be observed under the microscope, particularly at the snippet ends. Due to this partial solution, progressive elongation takes place after the initial rapid contraction. This contraction, which gave values in good agreement with normal equilibrium contraction, was in certain cases so rapid that it could not be photographed effectively at the one-second exposure-time used, and, consequently, no contraction values are shown in the figures. However, as the fibre is progressively exposed to atmospheric oxidation, the extent of partial solution decreases until final contraction values are eventually obtained corresponding to positive contraction. This is probably indicative of the restoration, through atmospheric oxidation, of the disulphide network which is mainly responsible for keratin stability. It would, therefore, be inadvisable to perform supercontraction studies on reduced wool unless precautions are taken to prevent reformation of cross-linkages.

Ultrasonic Detection of Choledocholithiasis

Present-day methods of detecting gall-stones in the common bile duct at operation are not wholly satisfactory. Stones may be missed in spite of careful palpation, cholangiography and direct exploration of the common bile duct. An attempt has been made to use pulsed ultrasound at the time of operation as an adjunct to their detection.

The apparatus used was a Kelvin and Hughes Mark V *F* flaw detector which is used industrially for the detection of flaws in homogeneous structures such as steel. The detecting probe contains both transmitting and receiving transducers and operates at 2·5 Mc./sec. The transducer emits pulsed ultrasound which is transmitted through a liquid or solid medium with attenuation and is reflected wholly or in part from the surface of any obstruction, the acoustic impedance of which differs sufficiently from that of the medium. The reflexion or echo is picked up by the receiving transducer and the electrical signal generated is amplified and displayed on a cathode ray oscilloscope with a linear time base to give a rough depth calibration (referred to as *A*-scope presentation).

Gall-stones of differing composition (cholesterol, pigment and mixed) and varying in size from 3 to 30 mm. were examined in a tank of saline and definite echoes were obtained from them. They were located by adjusting the position of the transducer head. The optimum range was 3–10 cm. Very slight movement of the transducer produced a marked difference in the size of the echo.

Similar findings were obtained from gall-stones in fresh post-mortem bile ducts and in gall-bladders removed at operation. There were, however, two main differences; the minimum size of gall-stone detectable in bile ducts was 6 mm., and detection proved difficult when the walls of the biliary ducts were grossly thickened by disease. Similar results were obtained when gall-stones in the common bile duct were detected at operation. To provide a liquid medium between the probe and the common bile duct, about 0·5 l. of sterile water was poured into the upper abdomen. The probe was enclosed in a sterile latex sleeve.

Although it is possible with *A*-scope presentation to use ultrasound to detect gall-stones in the common bile duct at operation, the technical difficulties are considerable[1]. It would seem that further research using *B*-scope with plan position indicator[2], which gives a two-dimensional picture, may have something more reliable to offer the surgeon.

We wish to express our gratitude to Prof. W. R. Spurrell, Prof. C. B. Allsopp, Prof. R. Warwick and Prof. G. W. Taylor in whose departments at Guy's and St. Bartholomew's Hospitals the work was carried out. We would also like to acknowledge a grant for this work from the Clinical Research Committee, Guy's Hospital, and to thank Messrs. Kelvin and Hughes for the generous loan of the ultrasonic flaw detector, and the London Rubber Co. for providing the latex sleeves.

BIOCHEMISTRY

Introduction of the 16α-Hydroxyl Group into Œstrogens by Streptomycetes

Papers concerned with the microbiological transformation of steroids have appeared frequently in the past seven years; however, no examples of the hydroxylation of steroids with a benzenoid *A* ring have been observed. We have been able to introduce a hydroxyl group into the 16α-position of œstrone and œstradiol with two strains of *Streptomyces halstedii* (*ATCC* 13,499 and *NRRL B*-2138) and *Streptomyces mediocidicus ATCC* 13,278.

The cultures were grown for two days in shake flasks at 28° on a medium which contained yeast extract, cerelose, 'NZ amine' type *B* (an enzymatic digest of casein purchased from Sheffield Chemical, Norwich, N.Y.) and calcium carbonate at an initial *p*H of 6·7. This growth in 100 ml. was used to inoculate 2 l. of the same medium contained in a 4 l. fermenter. This mixture was incubated at 28° with stirring at 1,750 r.p.m. and aeration at one volume per volume per minute for 22 hr. After this period, 500 mgm. of œstrone were added in powdered form. The *p*H of the broth was approximately 6·5. The fermentation was continued under the same conditions, for 24 hr. At this time, the whole broth was extracted twice with an equal volume of chloroform. The concentrated extract was qualitatively examined by means of paper chromatography[1] to determine the transformation products. A ferric chloride colour test was used. Two major transformation products plus œstrone were observed. These products were isolated from the extract by silica-gel partition chromatography in which ethanol was the stationary phase and methylene chloride the mobile phase. The effluent fractions which contained the first more polar compound, were combined. Crystals were obtained, m.p. 214–216°, $[\alpha]_D^{24} + 174{\cdot}8$ (methanol) λ(KBr, max.) 2·97μ (OH) 5·80 (17-ketone). The melting point and optical rotation are in good agreement with those published for 16α-hydroxyœstrone[2]. The second more polar compound which migrated on papergrams in the œstriol region was also obtained crystalline, m.p. 281–283°, $[\alpha]_D^{24} + 56$ (dioxane). These properties are the same as those reported for œstriol[3]. The infra-red spectrum is identical with that of authentic œstriol.

Œstradiol was also converted to 16α-hydroxyœstrone and œstriol. These results indicate the presence of both a hydrogenase and dehydrogenase as well as a 16α-hydroxylase in the above-mentioned micro-organisms.

Effects of *Tris*(*p*-Aminophenyl)-Carbonium Salts and Related Compounds on Experimental Schistosomiasis and Paragonimiasis

IN 1952, we initiated a programme directed toward the synthesis and biological evaluation of a variety of triphenylmethane derivatives as potential schistosomicides in the hope that a useful curative drug could be developed. To date, more than two hundred have been tested in albino mice and several in rhesus monkeys experimentally infected with a Puerto Rican strain of *Schistosoma mansoni*. Several compounds have also been tested against the lung fluke *Paragonimus kellicotti* in dogs. In the summary presented below, all amounts of drug are expressed as carbonium ion.

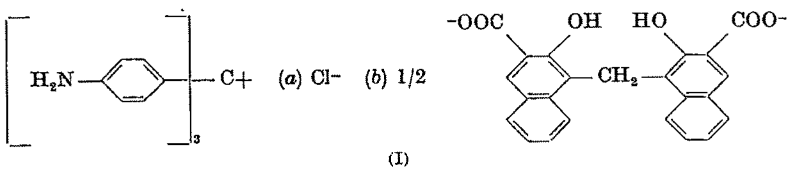
In the early stages, we found that a commercial sample of *para*rosaniline hydrochloride (also known as *para* magenta, basic magenta, magenta, parafuchsin (*e*), *para*-roseine, *CI*-676 (old) and *CI*-42500 (new)) exhibited a lethal effect on both mature and immature worms in mice when fed in the diet and against mature worms in monkeys when administered by gavage. These results demonstrated that a moiety present in the commercial dye might have not only therapeutic but also protective properties.

Chemical and physical analyses on various commercial samples of the dye indicated that *tris*(*p*-aminophenyl)carbonium chloride (TAC chloride) (I*a*) was usually the major component, although varying amounts of metal salts, *bis*(*p*-aminophenyl)-(4-amino-*m*-tolyl) carbonium chloride, 4,4′,4″-methylidynetrianiline, and N-aryl-*tris*(*p*-aminophenyl)carbonium salts were also present. Since the major moiety was the most likely active principle and such complex mixtures are not suitable for systemic use as drugs, we isolated a highly purified form of TAC chloride. The structure of this compound was substantiated by reduction to 4,4′,4″-methylidynetrianiline which was identical with authentic samples of this material prepared by the condensation of *p*-acetamidobenzaldehyde or 4,4′-diaminobenzhydrol with aniline. Subsequent testing of TAC chloride demonstrated that it had the antischistosome activity previously observed with the commercial dye and, in addition, protective activity in both mice and monkeys.

Although TAC chloride and its base [*tris*(*p*-aminophenyl)methanol](TAC hydroxide) were well tolerated in mice and monkeys at levels necessary for antischistosomal activity, such amounts of both compounds caused emesis and gastritis in dogs. We then searched for other TAC salts[1] which might retain good activity but cause less gastrointestinal reaction and this led to *tris*(*p*-aminophenyl)carbonium salt with 1/2 f.wt. 4,4′-methylene*bis*(3-hydroxy-2-naphthoic acid) (TAC pamoate) (I*b*). It was prepared[1] by allowing purified TAC chloride to react with the disodium salt of 4,4′-methylene*bis*(3-hydroxy-2-naphthoic acid) in aqueous methanol and was isolated as a hydrated green amorphous solid with an indefinite melting point, beginning at 220° C. A representative sample containing 2·5 per cent water of hydration has the following absorption spectrum: ($\lambda_{\max.}$ in 50 per cent MeOH–50 per cent *p*H 4·4 phosphate buffer (ε) 237 (133,000), 289 (50,300), 545 (188,000) mμ; $\lambda_{\max.}$ in 50 per cent MeOH–50 per cent 0·1 normal sodium hydroxide (ε) 288 (19,400), 365 (6,560) mμ).

Curative studies in mice established that TAC pamoate was active against mature worms over a wide range of well-tolerated doses (200–1,600 mgm./kgm./day) when given orally either in the food for 2–4 weeks or by gavage for 10 days. The dose-response curve was relatively flat. When administered intraperitoneally, the compound was only feebly active. The acute oral LD_{50} in normal mice is greater than 7 gm./kgm. In the monkey, TAC pamoate was well tolerated and suppressed ova production at gavage doses of 100–400 mgm./kgm./day for 10–20 days. TAC pamoate was much less emetic in dogs than TAC chloride.

Inasmuch as 4,4′,4″-methylidynetrianiline is a likely metabolite of the TAC salts[2], it was of interest to compare the schistosomicidal activity of this compound with TAC chloride *in vitro*. TAC chloride proved to be rapidly schistosomicidal *in vitro* at 50 γ/ml. and slowly lethal at 12·5 γ/ml., while 4,4′,4″-methylidynetrianiline was inactive within 72 hr. at these concentrations. These results suggest that TAC salts are schistosomicidal *per se*, but do not, of course, rule out the possibility that there may be active metabolites. Further investigations revealed that the antischistosomal effects of TAC hy-



(I)

droxide in mice were not reversed by massive doses of *p*-aminobenzoic acid, whereas the antitrypanosomal activity of commercial pararosaniline in mice is antagonized by the acid[3]. Worms in mice treated with TAC pamoate began to shift to the liver after seven days of medication; death of the worms lagged about six days behind the shift to the liver. Live schistosomes from mice treated for nine to eleven days were stained and examined microscopically for evidence of drug-induced damage. The principal changes were a reduction in the amount of pigment in the cæca of the females and atrophy of the vitellaria. In addition, there was a suggestion of atrophy of the oocytes in the posterior end of the ovaries. The general impression gained from these investigations is that TAC pamoate acts slowly by interfering with nutrition but has little obvious specific organ or tissue toxicity for the schistosomes.

When administered orally to dogs infected with *P. kellicotti*, both TAC chloride and TAC pamoate induced a sustained dimunition in egg production and egg abnormalities, which included shape variations, opaqueness, the appearance of a diffuse germinal mass, and indistinct vitelline cells. When normal adult lung flukes from an untreated dog were incubated for 4 days with 12·5 or 50 γ/ml. of TAC chloride in horse serum, the worms survived but produced similar abnormal eggs; the number was proportional to drug concentration. However, when normal eggs were incubated with 125–500 γ/ml. of TAC pamoate *in vitro*, the only change was a slight staining of the outer covering of the egg. Therefore, it seems likely that these TAC salts act on the reproductive system of these worms rather than on the intact eggs after oviposition.

Among the various triphenylmethanes we have synthesized and tested against *S. mansoni* in mice, the structural requirement for schistosomicidal activity is highly specific. Thus, *tris*(*p*-aminophenyl)-carbonium salts, or derivatives that afford such salts in normal use, such as *tris*(*p*-aminophenyl)methanol and 4,4′,4″-(methoxymethylidyne)trianiline, kill a high proportion of *S. mansoni* in mice. However, curative activity is abolished or drastically reduced when these structures are modified by: (1) reduction to the leuco base (4,4′,4″-methylidynetrianiline); (2) removal of one or two amino-groups; (3) alkylation, halogenation or sulphonation of the benzene rings; (4) alkylation of the amino-groups; (5) removal of one *p*-aminophenyl group; (6) replacement of one or more of the amino groups with a hydroxyl group or a hydrogen or chlorine atom; (7) replacement of the central carbon atom with a sulphur, nitrogen or arsenic atom. These results are in agreement with early reports by Wright *et al.*[4] and Schubert[5] that rosaniline, gentian violet and alphazurine lack appreciable action against mature *S. mansoni*.

During the last stages of this work, Yea-lin and Kuang-sheng[6] reported that rosaniline hydrochloride exhibits certain therapeutic effects on *S. japonicum* infections in mice and rabbits. Recently, Yea-lin[7] revised downward the claims of activity of rosaniline hydrochloride and reported *para*rosaniline hydrochloride to be effective against *S. japonicum* in mice. In several respects our results do not appear to parallel those reported by Yea-lin[7] on the activity of fourteen compounds related to rosaniline against *S. japonicum* in mice. However, uncertainty regarding the composition of the compounds he tested and differences in species and test methods employed preclude a satisfactory assessment of these differences.

Starch-gel Electrophoresis of Anterior Pituitary Hormones

SEPARATION of pituitary hormones by zone electrophoresis on paper has not proved very successful, possibly due to complex formation between proteins[1]. Starch-gel zone electrophoresis introduced by Smithies[2,3] separates proteins not only by their net charge but also by their molecular size. This procedure has superior resolving power to paper or agar-gel zone electrophoresis and has been successfully applied to the analysis of thyrotrophic hormone[4–6]. Starch-gel electrophoretic analyses of various standard preparations of anterior pituitary hormones are presented here together with some evidence of the distribution of hormonal activities.

A modification of the discontinuous buffer system of Poulik[7] was used. This system was found to separate pituitary proteins better than the original method of Smithies. The electrode vessels contained 0·1 *M* lithium hydroxide and 0·38 *M* boric acid. The gel was prepared with partially hydrolysed potato starch (Connaught Medical Research Laboratories, Toronto) and a buffer containing 90 per cent v/v 0·003 *M* citric acid, 0·016 *M* *tris*(hydroxymethyl)-aminomethane and 10 per cent 0·02 *M* lithium hydroxide, 0·076 *M* boric acid. Electrophoresis was carried out for 4–5 hr. at average voltages of 15–20 V. per cm. During this time sheep albumin moved about 16 cm. and the fastest components in sheep pituitary preparations about 30 cm. from the origin.

The gels were fixed and stained overnight in 0·01 per cent nigrosin (Gurr), in methanol/acetic acid/water 50 : 10 : 40 by volume.

Fig. 1 shows the patterns obtained on the bottom surface of the gels after electrophoresis of various anterior pituitary hormone preparations.

Ox growth hormone (*NIH B2*) has two main components (labelled *A* and *B*) migrating towards the cathode in addition to several minor components migrating to the anode. Several other purified ox and sheep growth hormone preparations have all shown components *A* and *B* but variable minor anodal components.

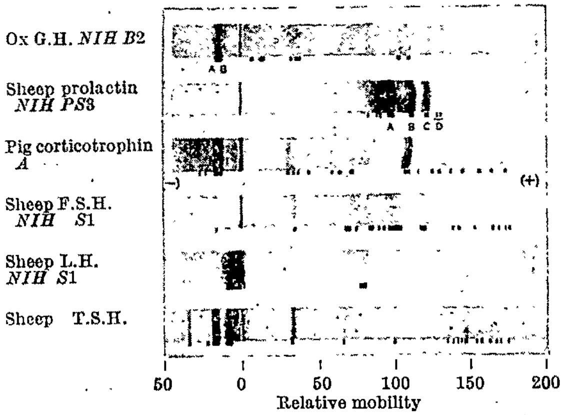

Fig. 1. Photographs of starch gels stained with nigrosin showing the patterns obtained with anterior pituitary hormone preparations. The samples were inserted at the position marked zero on the relative mobility scale and this scale was adjusted so that the prolactin component *A* had a relative mobility of 100

Components *A* and *B* were located in the unstained gel by serrating the edges of the gel with a template as described by Moretti *et al.*[8] and staining a slice from the top of the gel. The pieces of gel containing these components were homogenized with saline and assayed for growth hormone activity in hypophysectomized rats. Both components had approximately equal activity using the width of the tibial epiphysial plate and body-weight as responses. When the components were re-run by inserting the gel sections in a fresh gel they retained their characteristic mobility with no detectable overlapping.

Sheep prolactin (*NIH PS*3), 15 International Units per mgm., shows more than 20 components on the original gel, not all of which can be seen with the amount applied in the experiment illustrated. Purified sheep prolactin preparations from other sources showed similar distribution of the main components. Biological assay in pigeons showed at least 4 regions of the gel, labelled *A–D*, having prolactin activity. The main components in regions *A* and *B* in crude sheep pituitary extract have been separated on diethylaminoethyl-cellulose and have been differentially sedimented in intracellular particle preparations from sheep pituitary homogenate (unpublished experiments). However, separation of the components was less readily achieved when purified prolactin preparations were subject to chromatography on diethylaminoethyl-cellulose under the same conditions used for crude extract. Fractions from adjacent peaks after chromatography showed common starch-gel components. This suggests that purification procedures may have increased the tendency of the components to form complexes. A preparation of ox prolactin showed two active components, electrophoretically different from the sheep preparations.

Pig corticotrophin *A*, 108 International Units per mgm., obtained from a pharmaceutical firm, shows a main cathodal component and at least 21 minor components. The cathodal component is common to two other adrenocorticotrophic hormone preparations examined and has a mobility intermediate between the two growth hormone components.

Sheep follicle stimulating hormone (*NIH S*1) shows several minor components, some poorly resolved, but does not have any strongly staining component, suggesting that most of the material in the preparation does not stain heavily with nigrosin. Sheep luteinizing hormone (*NIH S*1) shows a main cathodal component with very little other material. No biological assay of components in corticotrophin *A*, follicle-stimulating or luteinizing hormone preparations has been carried out.

An impure preparation of sheep thyrotrophic hormone, 1·5 U.S. Pharmacopeia units per mgm., prepared in this laboratory shows at least 15 components. Wynston *et al.*[5] have described four components with thyrotrophic hormone activity in preparations from sheep pituitaries.

The existence of several proteins with one hormonal activity suggests that degradation of the hormone has occurred during fractionation. However, the same components have been found in fresh pituitary extracts subjected to no procedures other than homogenization and centrifugation. Polymorphism does not appear to account for the two active components of growth hormone, since extracts of individual sheep pituitaries all show both components. This hypothesis has not, however, been disproved for prolactin and thyrotrophic hormone. The various preparations examined were obtained from pituitary tissue and it remains to be shown whether multiple forms of anterior pituitary hormones are secreted.

We are grateful to the Endocrinology Study Section, National Institutes of Health, Bethesda, United States, for the supply of growth hormone, prolactin, follicle stimulating hormone and luteinizing hormone. An account of these experiments will be published in more detail elsewhere.

Polymorphism of α_1-Acid Glycoprotein

α_1-ACID glycoprotein[1,2], a human plasma protein of low molecular weight, has been prepared in a state of extremely high purity as evidenced by electrophoresis and ultracentrifugation over a *p*H range of 1–12 and by terminal amino-acid and immunochemical analyses. Starch-gel electrophoresis of this blood constituent at *p*H 8·5 according to Smithies[3,4] also demonstrated homogeneity. α_1-Acid glycoprotein is further distinguished by the unusually low isoelectric point reported to be at *p*H 2·7 and the high carbohydrate content accounting for 40 per cent and consisting of sialic acid, galactose, mannose, fucose and N-acetyl-glucosamine.

In view of the recently established genetically determined variations of certain plasma proteins[5–8], it appeared of interest to investigate whether or not a comparable polymorphism could be found for α_1-acid glycoprotein. Starch-gel electrophoresis was carried out at the following *p*H values: 7·2, 5·0, 3·8, 2·7 and 2·0. At its isoelectric point this glyco-

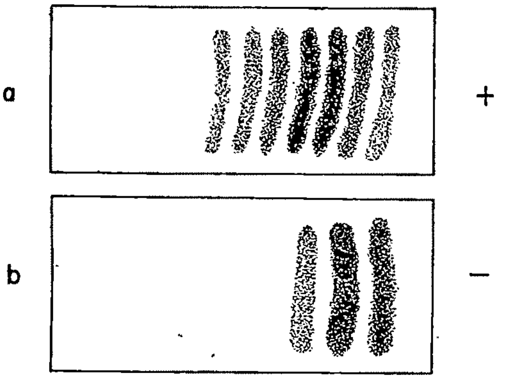

Fig. 1. Starch-gel electrophoresis of α_1-acid glycoprotein at pH 2·7 in $\Gamma/2$ 0·02 phosphate buffer (*a*) and of the sialic acid free form of this protein at pH 5·0 in $\Gamma/2$ 0·02 acetate buffer (*b*). Position of application of the proteins at the right end of the starch gel. Direction of movement from right to left

protein resolved into several bands, whereas on the acid and alkaline side of pH 2·7 homogeneity was observed. A typical preparation[1], derived from 248 litres of pooled outdated normal human plasma (from 1,100 donors of the Commonwealth of Massachusetts), exhibited seven zones (Fig. 1*a*). However, α_1-acid glycoprotein preparations from individual blood specimens separated into different numbers of zones.

To corroborate the validity of these findings, α_1-acid glycoprotein prepared from pooled plasma was treated with neuraminidase, effecting cleavage of essentially the total content of sialic acid, and again subjected to starch-gel electrophoresis. At pH 2·7 the resulting protein revealed a single band, but at the isoelectric point of the enzymatically modified glycoprotein, that is, at pH 5·0, three zones were noted (Fig. 1*b*). At higher pH values apparent homogeneity was restored.

Further work is in progress to determine the genetic implications of these observations.

We are obliged to Dr. J. A. McComb and his associates, Division of Biologic Laboratories, Massachusetts Department of Health, for providing the supernatant solution of Cohn's fraction V derived from pooled normal human plasma, and to Dr. E. H. Eylar, Harvard Medical School, and Dr. E. H. Schultze, Behring-Werke, Marburg-Lahn, Germany, for the gift of neuraminidase.

This work was supported in large part by grants from the National Institute of Arthritis and Metabolic Diseases, United States Public Health Service, Grant *A*-3564.

Role of Glutathione and of a Self-stabilizing Chain of SH-Enzymes and Substrates in the Metabolic Regulation of Erythrocytes

WE have already described the influence of intracellular glutathione on the activity of inorganic pyrophosphatase and triosephosphatedehydrogenase[1,2].

As shown in column 2 of Table 1, other SH-enzymes such as hexokinase, glutathione reductase, glucose-6-phosphatedehydrogenase are inactivated under conditions of oxidation of glutathione by phenylhydrazine according to Beutler[3]. Glucose affords partial protection as may be seen in column 3. The mechanism of the effect of phenylhydrazine is hæmin-catalysed oxidation of glutathione in the presence of oxygen[4,5]. Glutathionedisulphide, which is formed as an intermediate, causes oxidation, perhaps by formation of mixed disulphides, and inactivation of the essential SH-groups of the enzymes[6]. The oxidized enzymes, if not reduced, undergo within hours irreversible changes[1,6].

Table 1. INFLUENCE OF PHENYLHYDRAZINE ON THE ACTIVITY OF SH-ENZYMES

	Control	1	2	3
Incubation (hr.)	0	12	12	12
Phenylhydrazine (5 mgm./ml. suspension)	—	—	+	+
Glucose (2 × 10^{-2} M)	—	—	—	+
Glutathione reduced (GSH) (mgm./100 ml. cells	73·3	64·8	14·6	31·4
Hexokinase (M × 10^{-3}/l. cells/hr.)	18·1	21·9	2·7	23·4
Glutathione reductase (M × 10^{-2}/l. cells/hr.)	26·3	31·0	10·2	15·8
Glucose-6-phosphate dehydrogenase ΔE × 10^3/0·02 ml. hæmolysate/min.	30·2	24·6	7·0	17·8

The determinations of GSH (ref. 16), hexokinase (ref. 17), glutathione-reductase (ref. 18), glucose-6-phosphate dehydrogenase (ref. 19) were performed according to published methods.

Protection of the SH-enzymes is ensured by the reduced triphosphopyridine-nucleotide-forming reactions of the oxidative breakdown of glucose and the glutathione reductase[7]. The interrelation between the glutathione system (GSH/GSSG) and the SH-enzymes are depicted in Fig. 1.

The enzymes, which are concerned with the reduction of glutathione, carry essential SH-groups[8-10]. They are also inactivated when glutathione is oxidized.

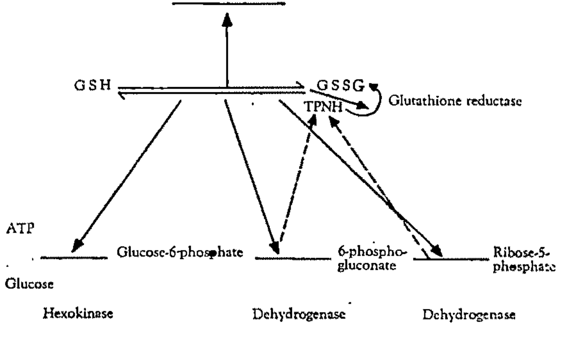

Fig. 1. Scheme of interrelations of enzymes and substrates of SH-metabolism

Thus the extent of enzymatic glutathione reduction is diminished. In case of prevalence of oxidative conditions, more oxidized glutathione would be formed, which in turn would inactivate the SH-enzymes, which participate in the reduction of glutathione. Thus a vicious cycle with destruction of SH-enzymes and glutathione would arise. The same chain of events would occur when one member of the enzymatic self-stabilizing chain of glutathione reduction is missing. Since the chain of SH-enzymes comprises hexokinase, the pacemaker of glycolysis[11], as well as the key enzymes of the oxidative breakdown of the glucose, the oxidation of glutathione might also lead to a decline of the metabolism of glucose and a diminution of formation of adenosine triphosphate with consequent breakdown of cell structure and hæmolysis.

It would appear that the system of SH-enzymes and their substrates plays a significant part in the regulation of metabolism and maintenance of structure of the cell, perhaps particularly for the processes of maturation and senescence[12–15].

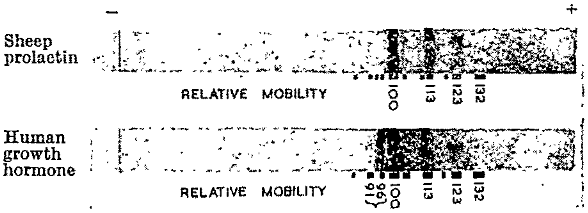
Prolactin Activity of Human Growth Hormone

Zone electrophoresis on starch-gel revealed that purified sheep prolactin contained at least four components with crop-sac stimulating activity in the pigeon[1]. Recently three preparations of purified human growth hormone made by different procedures in different laboratories have been examined by the same method. They all show a striking similarity to sheep prolactin in the mobility and relative amounts of the principal components. This similarity has also been observed by Barrett, Friesen and Astwood[2]. By contrast the patterns are quite unlike the patterns we have observed with ox, sheep, pig and whale growth hormone.



Growth activity percentage recovered 29, 39, 23, 10
Prolactin activity percentage recovered 41, 12, 9, 8

Fig. 1. Starch-gels stained with nigrosin showing patterns obtained with sheep prolactin and human growth hormone

A comparison of one human growth hormone preparation, prepared by Dr. Raben, with the standard sheep prolactin *NIH PS*3 is shown in Fig. 1. Amounts of the two preparations applied to the gel were 2 mgm. for the human growth hormone and 0·5 mgm. for sheep prolactin. Based on staining intensity, these amounts supply approximately the same amount of the principal components in each preparation. Biological assay of the two preparations for crop-sac stimulating activity gave relative potencies of the same order, the human growth hormone being 2·8 International Units per mgm. compared with the prolactin, which is rated at 15 International Units per mgm. The human growth hormone assayed against the ox growth hormone standard *NIH B*2, using the width of the tibial epiphyseal plate in the hypophysectomized rat, was found to be equal to it in potency. If, as may be inferred from the intensity of the components in relation to amount of human growth hormone applied, more purified preparations are possible, then a growth-promoting potency several times that of pure ox or sheep growth hormone may be attainable.

The major components are labelled by their mobility relative to the principal component of sheep prolactin, taken as 100. The amount of prolactin applied to the gel is insufficient to show up the minor components in the photograph. Components 100, 113, 123 and 132 appear in both preparations and correspond to those labelled *A–D* which had prolactin activity in the earlier investigation[1]. Components 123 and 132 in sheep prolactin can each be resolved into two components, but this did not occur in the analysis of the human growth hormone preparation.

In another experiment, components 91 and 96 combined, 100, 113 and 123 of the human growth hormone were cut out of the gel, having been located in the unstained gel as described earlier[1]. The amount of gel with each component was equalized by adding blank gel to the narrower components. The separate fractions were assayed for prolactin and growth hormone activity. For both assays single dose levels and six pigeons or rats per fraction were used. The same proportion of the total amount of each component present in the gel was injected. In the same assays were included two dose-levels of standard prolactin, *NIH PS*3 and standard growth hormone, *NIH B*2, respectively, homogenized with the same amounts of starch gel as the separate components. Also included was a single dose-level of the human growth hormone similarly treated.

All the components of human growth hormone tested were found to have both prolactin and growth hormone activity. The only estimate of the relative amounts of each component at present available is based on staining intensity and may be biased by different affinities of the components for the dye. Accordingly, rather than give doubtful relative potency figures, only the proportion of the activity applied to the gel (corrected for the amount removed in the top section and edges) appearing in each of the components is shown in Fig. 1.

Components 91 and 96 contain a considerable proportion of activity and must have a high potency. The minor components which occur in this region of sheep prolactin have not been tested for prolactin activity. The recovery of activity in the components accounts for somewhat less than the estimated activity applied to the gel for prolactin. However, the discrepancy is within the error of the assay. The ratio of growth hormone to prolactin activity is not constant for the different components, but further bioassays are required to confirm this.

Although the significance of the multiple active components remains to be discovered, it seems likely that the prolactin activity of human growth hormone is not due to contamination, but is a function of the same molecules that possess growth hormone activity.

The similarity of the starch-gel electrophoretic patterns of human growth hormone and sheep prolactin suggests that human growth hormone as now prepared may be chemically and phylogenetically more closely related to the prolactins than to the growth hormones of the ox and sheep, the species most studied in this respect. Further similarity is seen in the chemical and physical properties of the two hormones[3,4]. In molecular weight and amino-acid composition, the growth hormones of different species investigated appear to fall into two groups quite distinct from one another, except that both possess carboxyl and amino-terminal residues of phenylalanine. The group comprising man, monkey and pig is similar to sheep and ox prolactin except in terminal amino-acids, and it is tempting to suggest that monkey and pig growth hormone may also have prolactin activity. However, the starch-gel electrophoretic pattern of pig growth hormone does not resemble that of sheep prolactin.

It is well established that primates do not respond to ox growth hormone[5]. However, it is not certain that a growth hormone related to the hormone of the ox, sheep and whale is absent in primate pituitaries or indeed in the pig. For example, Wilhelmi's method[6,7] for the extraction of ox growth hormone applied to human pituitaries[13] leaves behind much of the growth activity which can then be extracted with solvents which normally extract sheep prolactin. It is possible that some of the growth hormone initially extracted is not identical to that which is brought out by the later extraction.

Sheep prolactin has been shown to have growth hormone-like effects on glucose-tolerance and insulin-sensitivity in dogs[8] and monkeys[9], while stimulation of nitrogen retention in humans[10] and body growth in pigeons[11] and rats[12] has been reported. Such evidence makes it less surprising that human growth hormone preparations should possess both growth hormone and prolactin activity, and suggests that the metabolic effects of prolactin may be a more important part of its function than has been generally recognized.

We are indebted to Dr. M. S. Raben for the gift of human growth hormone and to the Endocrinology Study Section, U.S. National Institutes of Health, for the gift of sheep prolactin.

Nitrogen and Sulphur at the Active Centre of Carboxypeptidase *A*

A series of metallocarboxypeptidases has been prepared by the substitution of manganese, cobalt, nickel, copper, cadmium, or mercury for zinc, the element present in and essential to the enzymatic activity of native carboxypeptidase *A* [1]. The stability constants, peptidase and esterase activities of these derivatives have been studied and compared[1-3]. Zinc is bound to the single sulphydryl group of the apoenzyme[4-6], as is cobalt as evidenced by its exchange with zinc and by the spectral changes which accompany its binding[2,6]. It has been suggested that a sulphur and a nitrogen atom of carboxypeptidase, together with a metal atom, constitute the active centre of the enzyme, their interaction being required for activity[5].

We now wish to present further evidence in support of the hypothesis that a nitrogenous group is involved in the binding of metals to the active site of carboxypeptidase *A*. The stabilities of the complexes of these metals with a series of nitrogen–sulphur bidentate ligands correlate closely with the affinity of these metals for the binding site on apocarboxypeptidase. The apparent stability constants of the metallocarboxypeptidases in Table 1 (col. 1) have recently

Table 1

Metallocarboxypeptidase	1	2

[(CPD)Mn]	5·6	5·6
[(CPD)Co]	5·8	7·0
[(CPD)Ni]	5·7	8·2
[(CPD)Cu]	5·1	10·6
[(CPD)Zn]	8·3	10·5
[(CPD)Cd]	7·5	10·8
[(CPD)Hg]	6·7	21·0

* 1 gm. atom of methyl per mole of protein.
† Determined in 1 *M* sodium chloride, 0·05 *M tris*, *p*H 8·0, 4° C.
‡ Corrected for the reduction of (Me_{free}) by the competing *tris* and Cl^- complexes.

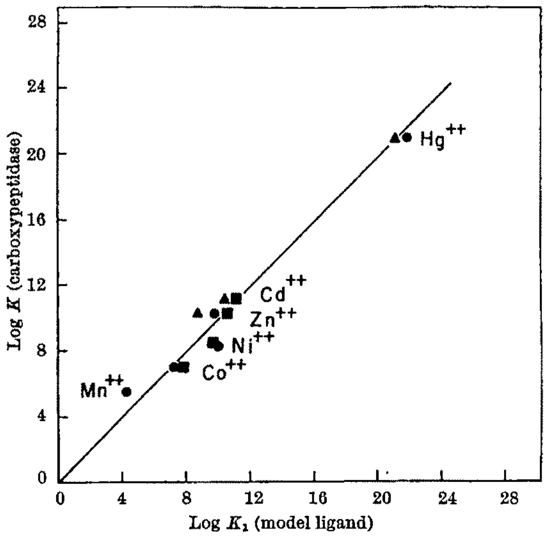

Fig. 1. Correlation of log $K_{corr.}$ for carboxypeptidase with log K_1 for sulphur–nitrogen ligands. ●, cysteine; ■, mercaptoethylamine, corrected for the presence of 0·1 M KCl; ▼, glutathione. All log K_1 values are taken from ref. 7

been measured at pH 8, 4° in 0·05 M *tris*(hydroxymethyl)aminomethane and 1 M sodium chloride, the latter required to dissolve the enzyme, which is otherwise quite insoluble. In these circumstances, zinc is bound more firmly than any of the other metals studied. Allowing for the complexation of the different ions by *tris* and chloride, an appropriate correction must be made for each to ascertain the true stability constants. As is evident from Table 1 (col. 2), this correction is particularly large for mercury. We have compared the stability of these metallocarboxypeptidases with similar data from the literature[7] for cysteine, glutathione, and 2-mercaptoethylamine, which form complex metal ions with nitrogen and sulphur as the donor atoms (Fig. 1).

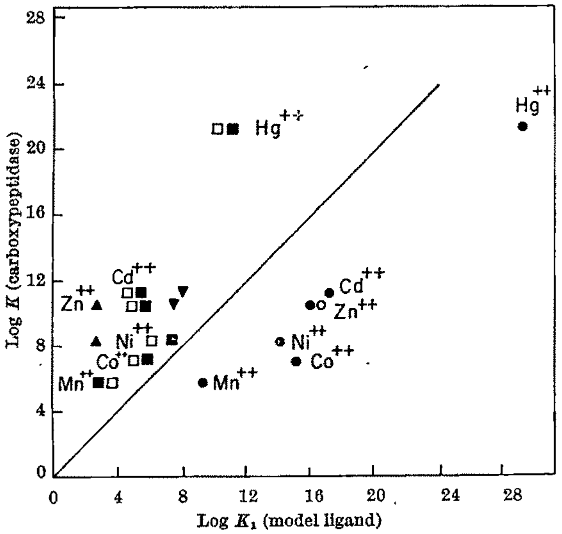

Fig. 2. Lack of correlation of log $K_{corr.}$ for carboxypeptidase with log K_1 for nitrogen–oxygen, nitrogen–nitrogen, sulphur–sulphur, and sulphur–nitrogen–oxygen–oxygen ligands. □, glycine; ■, ethylenediamine; ▲, α-mercaptobutyric acid; ▼, mercaptoacetic acid; ●, 2-mercaptoethyliminodiacetic acid; O, dimercaptosuccinic acid. All symbols refer to the ion appearing on the same horizontal level as the symbol, except for Cd^{++}, which is slightly displaced from the symbols in both instances. All log K_1 values are taken from ref. 7

The high correlation of the stability constants of the metallocarboxypeptidases with those of the complexes of the corresponding metals with these nitrogen–sulphur ligands is striking, and implies a common denominator. We believe that these results strongly support the hypothesis that, together with the single —SH group of the enzyme, a nitrogen atom is involved in binding zinc and other metals to the apocarboxypeptidase.

In Fig. 2 these enzyme stability constants are plotted against those of nitrogen–oxygen, nitrogen–nitrogen, and sulphur-oxygen bidentate ligands as well as a sulphur–nitrogen–oxygen tetradentate ligand. In contrast with Fig. 1 there is marked scatter of the data ruling out any of the modes of binding shown by these ligands as being consistent with that of carboxypeptidase A. The constants for disulphide ligands are orders of magnitude higher than those of carboxypeptidase, as exemplified by the chelate of zinc with dimercaptosuccinic acid, also shown in Fig. 2.

It is therefore suggested that the active centre of native carboxypeptidase A includes one sulphur, one nitrogen, and one zinc atom. Present evidence indicates that the nitrogen atom is either part of an α-amino or, perhaps, an imidazole group[3]. Studies to differentiate between these are in progress.

Similarity of Peptides in Two Antigen-combining Fragments released from a Rabbit Antibody by Papain

DURING an examination of the enzymatic hydrolysis of rabbit γ-globulin, it was noted that only one-half to two-thirds as many peptides could be differentiated in the hydrolysates as was expected from the amount of base needed to maintain pH during hydrolysis: approximately 50 peptides were distinguished following hydrolysis of rabbit antibodies with trypsin, 70 following chymotrypsin and 100 following subtilisin, whereas approximately 100, 150 and 210 μmoles of sodium hydroxide per μmole of antibody respectively were required to maintain pH at 8·0. The results suggested the possibility that similar or identical peptides were released from different parts of the same molecule resulting in a smaller number of

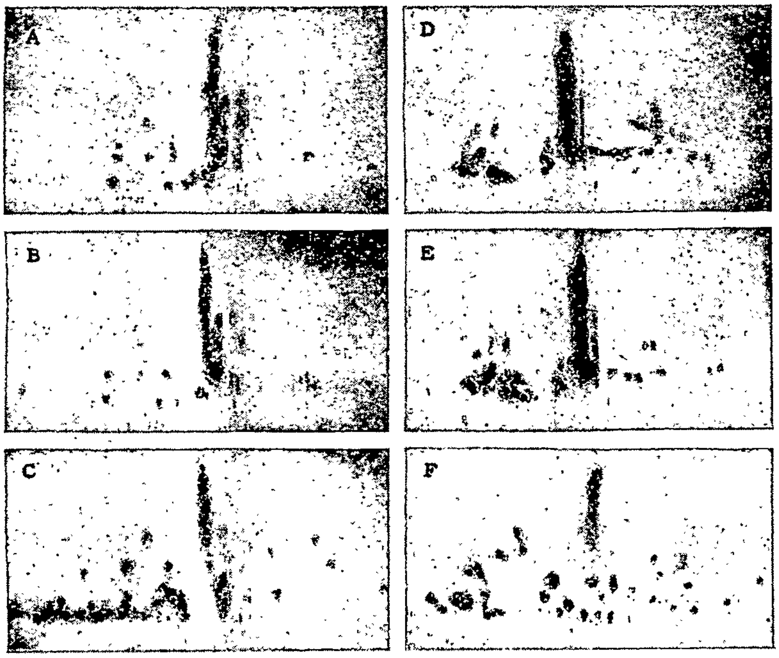

Fig. 1. Peptide patterns of chymotrypsin hydrolysates of I (*A*), II (*B*) and III (*C*) and of the subtilisin hydrolysates of I (*D*), II (*E*) and III (*F*). In each figure, the length of the vertical stroke demarcating the origin at the bottom centre was 7 mm., the anode was to the right and solvent chromatography was in vertical direction

detectably different peptides than the number of peptide bonds broken. An opportunity to test this hypothesis was afforded by Porter's isolation of three large peptide fragments from papain hydrolysates of rabbit γ-globulin[1]. Two of these, I and II, had antibody characteristics and together comprised 50–60 per cent of the antibody molecule; the third fraction, III, was easily crystallized but had no antibody activity. In the work reported here, the peptides of these three fragments were compared.

Rabbit antibodies against type VII *Pneumococcus* polysaccharide were isolated from pooled type-specific rabbit γ-globulin by precipitation with homologous antigen. The specific precipitate was washed four times with 0·15 *M* sodium chloride, suspended in 0·1 *M* potassium chloride containing 0·01 *M* cysteine and 0·002 *M* sodium ethylenediaminetetraacetate and hydrolysed in the *p*H-stat[2] at *p*H 7·0 [1] with twice-crystallized papain in an enzyme to antibody ratio of 1 : 1,000 by weight. The hydrolysate was kept at 2° C. for 2 days and the crystals which formed, fraction III, were collected and recrystallized twice. The remainder of the hydrolysate was dialysed against distilled water and fractionated on a carboxymethyl cellulose column using a *p*H 5·5 acetate gradient, 0·005–0·9 *M*[1]; all column fractions other than I and II were discarded. Type VII polysaccharide was readily detected immunochemically in I and II but not in III. In accord with this, S_{w20} for III in the ultracentrifuge was 3·5 while I and II sedimented much more rapidly, the sedimentation constant depending on the ratio of antibody to antigen in the specific precipitate; the rate of sedimentation of I and II could be decreased by the addition of type VII polysaccharide, in keeping with a decrease in the size of an antigen-antibody complex.

The three fractions were oxidized with performic acid[3] and hydrolysed in the *p*H-stat at *p*H 8·0 with chymotrypsin or subtilisin. 0·1–0·4 mgm. of peptides were applied to a 23 × 57 cm. sheet of Whatman No. 1 filter paper and electrophoresis performed at 52 V./cm. for 45–50 min. at 21–28° C. under 'Varsol' (Esso Standard Oil Co.) at *p*H 4·2 (0·5 per cent pyridine in 0·2 *M* acetic acid). The papers were dried and subjected to ascending chromatography with 2,4,6-collidine, 2,6-lutidine and water in a volume ratio of 1 : 1 : 1. The peptide patterns were developed with ninhydrin.

Approximately 35 peptides could be differentiated in the chymotrypsin hydrolysates of I and II (Fig. 1, *A* and *B*) and about 50–55 in those of III (Fig. 1 *C*). The peptide patterns obtained for the subtilisin hydrolysates of I and II revealed 55 to 60 peptides (Fig. 1, *D* and *E*) and 70 to 75 peptides in the subtilisin hydrolysates of III (Fig. 1 *F*). Per μmole of I, II and III[4], 35, 35 and 60 μmoles of sodium hydroxide were used respectively during chymotrypsin hydrolysis and 60, 60 and 90 μmoles during subtilisin hydrolysis.

As can be seen from Fig. 1, the peptide patterns for I and II hydrolysed under the same conditions were almost identical; a few reproducible differences were apparent. The patterns for III differed quite markedly from those of I and II, but overlapping of some peptide positions in hydrolysates of III with those of I and II was noted.

It would appear, therefore, that approximately half the spots in the patterns obtained for total antibody hydrolysed with chymotrypsin or subtilisin contained peptides derived from at least two different parts of the same molecule. Since rabbit γ-globulin appears to have a single peptide chain[5], it is interesting that two large portions, each equivalent to almost one-third of the chain and each containing an antigen-combining site of the antibody, should have very similar peptide structures.

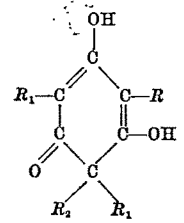
'Sunlight' Flavour of Beer

The fact that an unpleasant flavour occurs on exposing beer to sunlight was first reported by Lintner in 1875 [1]. Since that time much work has been carried out on this phenomenon. No explanation, however, has yet been given.

We have observed by quantitative determination that volatile mercaptan was formed in beer exposed to sunlight[2]. It has been found that humulones (*a*, *b*, *c*) and lupulones (*d*, *e*, *f*) present in hops are related to the formation of 'sunlight' flavour[3]. Furthermore, it has been observed that 'sunlight' flavour was formed even when humulone or lupulone was added, without being heated, to a fermented solution of sucrose or Japanese *sake*[4]. Among the synthetic lupulone analogues (*g*, *h*, *i*, *j*) only acetolupuphenone (*g*) caused sunlight flavour as does humulone and lupulone (ref. 4 and unpublished results).



a, *d*, $R=(CH_3)_2\cdot CH\cdot CH_2CO—$
b, *e*, $R=(CH_3)_2\cdot CH\cdot CO—$
c, *f*, $R=CH_3\cdot CH_2\cdot (CH_3)\cdot CH\cdot CO—$
a, *b*, *c*, $R_1=(CH_3)_2\cdot C=CH\cdot CH_2—$ $R_2=OH$
d, *e*, *f*, $R_1=R_2=(CH_3)_2\cdot C=OH\cdot CH_2—$
g, *h*, *i*, *j*, $R=CH_3CO—$
g, $R_1=R_2=(CH_3)_2\cdot C=CH\cdot CH_2—$
h, $R_1=R_2=CH_3\cdot CH_2\cdot CH_2\cdot CH_2—$
i, $R_1=R_2=CH_3CH_2CH_2—$
j, $R_1=R_2=CH_2=CH\cdot CH_2—$

We have now shown that humulone and acetolupuphenone are degraded by photochemical action and that the 3-methyl-2-butenyl group may be split off. 'Sunlight' flavour is recognized when a mixture of humulone or acetolupuphenone and cysteine is exposed to sunlight under conditions in which oxygen in the solution is replaced by carbon dioxide.

3-Methyl-2-butenyl mercaptan (b.p. 125–127° C.) was synthesized by the method of Braun and Plate[5]. This mercaptan produced the typical sunlight flavour of beer when it was added in trace amounts to a fermented solution of sucrose.

On the basis of this experimental evidence, it may be concluded that sunlight flavour of beer is 3-methyl-2-butenyl mercaptan and that it is formed by a photochemical reaction between the 3-methyl-2-butenyl group in the molecules of humulones or lupulones and certain sulphur-containing compounds present in beer.

PHYSIOLOGY

Metabolic Origin of Urinary Methylamine in the Rat

It has been shown[1] that certain monoamine oxidase inhibitors containing the hydrazine moiety (pheniprazine and iproniazid) besides increasing the level of urinary tryptamine[2] and β-phenylethylamine[3] produce a rise of as much as 300 per cent in the amount of urinary methylamine excreted by rats. To demonstrate the origin of this additional methylamine, rats were injected with compounds which, on the basis of their structure, appeared to be possible precursors of this substance. The compounds studied were glycine, sarcosine, dimethylglycine, betaine, creatine and DL-methionine. 100 mgm. of the compound to be tested was made up in isotonic solution to neutral *p*H and injected into the rat intraperitoneally.

To determine the effect of a monoamine oxidase inhibitor on the metabolism of these substances 1 mgm. of pheniprazine was injected intraperitoneally into each of three rats three hours before they received the possible methylamine precursors ; a second group injected with saline functioned as controls. The rats (Wistar, male, 250 gm.) were placed after injection in metabolism cages in groups of three, fed on Wayne Lab. 'Blox' and water *ad libitum.* Urine was collected for 24 hr. and the level of both methyl- and dimethylamine in the sample determined as previously described[1]. The levels of methylamine, expressed as percentages of the controls, are shown in Table 1. Levels of dimethylamine are not shown because they were not significantly altered by any of the treatments.

Table 1. LEVELS OF METHYLAMINE IN URINE FROM RATS INJECTED WITH POSSIBLE PRECURSORS OF METHYLAMINE IN THE PRESENCE AND ABSENCE OF PHENIPRAZINE
(Expressed as per cent of controls (upper and lower values in parentheses))

Treatment	Untreated: methylamine-level	No. of exp.	Pheniprazine treated: methylamine-level	No. of exp.
Saline	100	–	305 (257–375)	4
Glycine	176 (130–250)	6	468 (360–555)	3
Sarcosine	230 (178–280)	4	612 (540–690)	3
Dimethylglycine	108 (100–120)	4	300 (260–356)	4
Betaine	102 (88–124)	3	460 (405–515)	2
Creatine	159 (146–173)	2	1,240 (1,160–1,320)	2
DL-Methionine	101 (88–114)	4	337 (255–405)	5

In the absence of pheniprazine, three compounds, sarcosine, glycine and creatine, produced significant increases in levels of methylamine, sarcosine being considerably more active in this respect than the other two. Betaine, dimethylglycine and methionine had no effect. Injection of pheniprazine raised the level of methylamine about 300 per cent as was shown previously. This increase was not significantly affected by subsequent injections of either dimethylglycine or methionine. It was raised to more than 400 per cent by glycine and betaine, to 612 per cent by sarcosine and to 1,240 per cent by creatine. Urine collected on the second day showed even greater increases with sarcosine (1,800 per cent) and betaine (730 per cent).

According to the present results, sarcosine and creatine (of the compounds studied), appear to be the most likely precursors of methylamine. Sarcosine may give rise to methylamine through the enzyme glycine oxidase first reported by Ratner *et al.*[4]. Deamidination of creatine would produce sarcosine, which may in turn be demethaminated to yield methylamine and glyoxylate. Should an alternative route of metabolism of sarcosine (namely, sarcosine oxidase) be blocked by pheniprazine the level of sarcosine available for metabolism by way of glycine oxidase would be increased.

Horner and MacKenzie reported that both methionine and betaine may serve as methyl donors for the methylation of glycine to sarcosine[5]. However, in the present work only betaine facilitates production of methylamine in the presence of pheniprazine. This may well indicate that betaine or its biologically active derivative is the major methylating agent for glycine.

Ubiquinone and Tocopherol in Birds

UNLIKE the rat and the rabbit, it seems from nutritional studies made by several groups of workers that the chicken needs little vitamin E, providing its diet contains an adequate supply of selenium and only limited amounts of unsaturated fat[1-3]. Since tissue-levels of ubiquinone in the rat[4] and rabbit[5] are high compared with those given for some other animal species[6] and since these levels have been found to be dependent on vitamin E [4,5], it was of some interest to investigate tocopherol- and ubiquinone-levels in the chicken and some other avian species, with particular reference to those which show considerable differences in their basal metabolic rates. Chickens were reared to 7 weeks on an ordinary commercial ration, and a group of 4 pigeons and 12 canaries were purchased as adult birds from a commercial supplier. Selected tissues from each species were examined for ubiquinone, ubichromenol and α-tocopherol by analytical methods described previously[7].

As shown in Table 1, extremely low levels of tocopherol were confirmed in the young chicken, and the ubiquinone-levels in this species were among the lowest yet observed by us in animal tissues. The tissues of the pigeon and canary contained considerably higher concentrations of both ubiquinone and tocopherol. The level of ubiquinone in the powerful pectoral muscle of the pigeon is particularly interesting in view of the very high metabolic activity of this tissue (which is known to contain high levels of other enzymes and co-factors concerned with oxidation): it is quite an exceptional concentration compared with those found in muscles of other species we have examined. The uniformly high levels of ubiquinone in all the tissues of the canary can also be related to the high basal metabolism in this species[8]. On chromatographic examination, all the tissues of these birds, which were fed ordinary mixed diets, were found to contain only ubiquinone-50. However, other ubiquinones could easily be introduced into the tissues of the birds by feeding them diets containing yeasts, which contain lower isoprenologues of ubiquinone-50: in the latter case there was a marked difference in the isoprenologue pattern of the various avian tissues.

Table 1. UBIQUINONE (UQ), UBICHROMENOL (UC) AND TOCOPHEROL (T) IN THE TISSUES OF SOME BIRDS

Species	Tissue	UQ (μgm./gm.)	UC (μgm./gm.)	T (μgm./gm.)
Fowl	Heart	18	3	1·4
	Liver	13	1	0·9
	Breast muscle	1·4	0·2	1·5
Pigeon	Heart	192	12	6·8
	Liver	47	not detected	15·4
	Breast muscle	136	8	0·6
	Gizzard	3	0·2	1·4
Canary	Heart	242	17	17·9
	Liver	52	3	8·0
	Breast muscle	38	3	5·0
	Gizzard	43	4	3·9

Although these results are preliminary in some respects, they are not without significance, and tend to support the concept that there is a relationship between tocopherol, ubiquinone and oxidation processes in animals. Although the three species examined were not on identical diets and the latter may have differed somewhat in vitamin E content, this is a factor that, as Edwin *et al.*[4] have shown, has only a minor bearing on the concentration of tocopherol accumulated by the tissues. The differences described in Table 1 undoubtedly reflect real species variations. The role of vitamin E and selenium in the control of ubiquinone in avian species will be discussed in a more detailed report elsewhere.

Metabolism of *Gerbillus pyramidum*

THE genus *Gerbillus* comprises about thirty species which are distributed throughout Africa. *G. pyramidum* or the greater Egyptian gerbil, as it is also called, is found in Arabia, across North Africa to Morocco on the west and down eastern Africa through the Anglo-Egyptian Sudan to Kenya and Tanganyika[1].

The species discussed in this communication, *G. pyramidum*, differs somewhat from the Mongolian gerbil, *Meriones unguiculatus*, in that it is a larger and heavier animal with a less-docile temperament.

Because there are geographical and climatological differences in the habitats of the two species, inherent differences in their energy metabolism and body temperature regulation might also occur.

Oxygen consumption was measured by means of a closed circuit apparatus which incorporated a commercial recording servo-spirometer (Mouse Spirometer, model 160, Custom Engineering and Development Co., St. Louis, Missouri).

Twenty-one animals were used in the metabolic phase of this investigation, ten males and eleven females, ranging in weight from 72 to 145 gm. The conditions under which the oxygen consumption was measured are those described in a previous paper dealing with the Mongolian gerbil, *Meriones unguiculatus*[2]. The animal was housed, during the test period, in a small glass chamber, which contained soda lime for absorption of carbon dioxide. The chamber was immersed in a thermostatically controlled water-bath which could be set at any desired ambient temperature. After the animal was put in the chamber, an equilibration period of at least 1 hr. was allowed to elapse before the experimental period was begun. The experimental period lasted about 50 min. At least two consecutive runs had to agree closely before the resultant value was accepted. Metabolic measurements were made at ambient temperatures of 15–40° C. and expressed as oxygen consumption in ml./gm. body-weight/hr. This measurement should be regarded as being that of the resting metabolism, since the animals were not in a fasting state.

Least squares fitting of curves to the data, for temperatures below 30° C., yielded the equation $X = 3{\cdot}88 - 0{\cdot}102\ Y$, where Y represents ambient temperature, and X oxygen consumption in ml./gm. body-weight/hr. The correlation coefficient of this curve is 0·904. The critical temperature for *G. pyramidum* seems to be 30° C. Below this temperature, metabolism increases in a linear fashion, with decreasing ambient temperature, at the rate of 0·102 ml. oxygen/gm./hr./deg. C.

Oxygen consumption rises sharply at temperatures above 30° C. The regression line between 30 and 40° C. is $X = -3{\cdot}92 + 0{\cdot}146\ Y$. Between 30 and 40° C. there is a somewhat greater scatter of the results for each of the temperatures at which metabolic measurements were made. As a result the correlation coefficient for the regression line is 0·611.

It was not feasible to measure simultaneously the body temperature and oxygen consumption. Therefore, in order to ascertain thermo-regulatory capacity, it was necessary to expose another group of animals to ambient temperatures similar to those encountered in the metabolic chamber. Five animals were used in this phase of the investigation.

The gerbils were individually housed in large open-top plastic boxes in the hot room. Water was provided, although very little, if any, was consumed. Rectal temperatures were taken with a small thermocouple just before entering the room, and thereafter at hourly intervals. The probe was inserted to a point approximately level with the lower lobe of the liver. This point in our experience approximates the true reading of core temperature. The ambient temperatures chosen were 35 and 40° C. Table 1 summarizes the results of these exposures. The 2-hr. value is included both to enable comparison with the other species, *M. unguiculatus*, and to indicate the thermal state of the animal at the end of a metabolic measurement which usually took 2 hr.

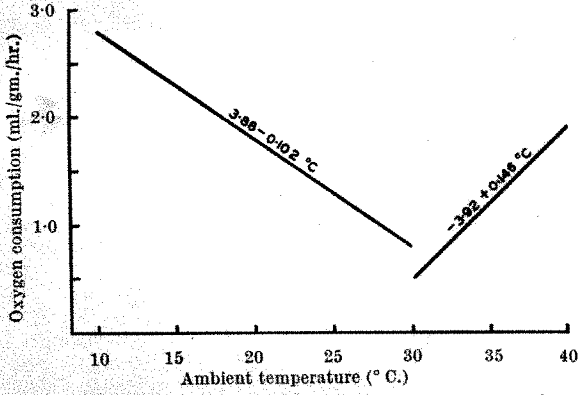

Fig. 1. Effect of ambient temperature on oxygen consumption in *Gerbillus pyramidum*

Table 1. Summary of the Results of Exposure of Gerbils to Heat

Ambient temperature (° C.)	Body temperature (° C.)						
	Mean control at 23° C.	After exposure to heat			Change		
		2 hr.	4 hr.	6 hr.	2 hr.	4 hr.	6 hr.
35	38·7	39·4	38·7	39·1	0·7	0·0	0·4
40	38·1	40·9	42·6	—	2·8	4·5	—

It is clear that while the African gerbil is not greatly inconvenienced at 35° C., even after 6 hr. exposure, it is incapacitated at 40° C. within a very short time. Visual observation alone confirms this. The animals salivate and wet their chests and lie down in a sprawled position, frequently shifting their position as if to seek a cooler location. This behaviour is much like that described by Schmidt-Nielsen[3], Herrington[4] and others[5,6] for the common laboratory animals. It is in sharp contrast to the behaviour of the Mongolian gerbils, which at a similar temperature did not appear to be uncomfortable even though they were exposed for a longer period. Two of the African gerbils exposed to 40° C. died in less than 3½ hr.; two others which seemed severely affected were removed to a cool environment at 4 hr., but died later. Their body temperature at the time they were removed had reached 43·5°.

It is evident from the foregoing results that the metabolic pattern of the African gerbil, *G. pyramidum*, is similar to that of the albino rat. In both animals the resting metabolism is increased between two- and three-fold as the temperature is decreased from 25–10° C. The critical temperature for both species is about 30° C. with a very narrow zone of thermoneutrality. This result is in accord with the pattern for tropical mammals as discussed and illustrated by Scholander[7]. The present results are unlike the metabolic pattern displayed by the Mongolian gerbil, *M. unguiculatus*. The Mongolian species shows an increase in metabolism between 25 and 10° C. (similar to that of the African species) but quite unlike the African species *M. unguiculatus* has a zone of thermal neutrality extending from 30–40° C. This difference between the two species may be due, in great part, to the superior capacity of *M. unguiculatus* to regulate its body temperature in a hot environment. It is likely that *G. pyramidum* spends the daylight hours in burrows where the conditions of temperature and humidity do not tax the animal's heat-regulatory mechanism.

Spectral Sensitivity of Single Visual Cells

SINCE the work of Young and Helmholtz, the highly developed colour vision in man and many animals has been thought to depend on several, usually three, retinal receptors with different spectral sensitivity[1,2]. Such a theory is best suited for the explanation of human sensations, of animal reactions, and of electrical responses of the whole eye. It is, however, very difficult to determine the spectral sensitivity of the postulated single receptors using these methods. The existence of different photosensitive pigments has been demonstrated by chemical methods in vertebrates[3], and *in vivo* photometric measurements have shown them for the mammalian retina[4]. But this again does not give us an entirely satisfactory explanation of the principal unit-level functions, and the very successful chemical analyses of the visual pigments do not help us understand colour vision[5].

Hitherto, electrical recordings from single elements in the vertebrate retina have been carried out only on the level of ganglion cells and not on the level of single receptors[5,6]. It is clear from these experiments that in the layer of bipolar cells and in the inner plexiform layer we are dealing with the integrated activity and not with the primary reactions of visual cells. Electrical recording from single visual cells of the blowfly (*Calliphora erythrocephala*) was made successfully, using microelectrodes with a tip diameter of approximately 0·1μ (ref. 7).

On the basis of results of electrophysiological and behavioural experiments, colour vision appears to exist in *Calliphora*, and the spectral sensitivity of the whole eye is well known[8]. The study of the spectral sensitivity of single visual cells in this animal may provide information necessary for the understanding of colour vision in arthropods and might probably provide a model for colour vision in general. Basic properties of the receptor potentials, the mechanism of analysing the plane of polarized light in the ommatidia, and details of the methods are described elsewhere[7,9].

In the present experiments, stimulating lights were monochromatic flashes of equal quanta and of 0·1 or 0·02 sec. duration with an interval of 10 sec. The spectral range 315–681 mμ was covered by a series of narrow-band interference filters with a mean wave-length interval of 19 mμ between filter peaks.

The spectral sensitivity of 39 single visual cells was determined for the wild form of *Calliphora*; additional experiments were performed with the white-apricot mutant, in which the red screening pigment is absent.

All cells in the dorsal part of the eye have a uniform sensitivity curve with one maximum at 489 mμ, $\sigma = \pm 7$ mμ, and a second maximum in the ultra-violet at 345 mμ, $\sigma = \pm 3$ mμ. Three different receptor types were found in the ventral part of the eye: (1) a green receptor similar to that in the dorsal part with one maximum at 491 mμ, $\sigma = \pm 6$ mμ, and a second maximum in the ultra-violet, again at 345 mμ, $\sigma = \pm 1$ mμ; (2) a blue receptor with one maximum in the visible part of the spectrum at 468 mμ, $\sigma = \pm 6$ mμ, and a second maximum again at 345 mμ, $\sigma = \pm 2$ mμ in the ultra-violet; (3) a yellow-green receptor with one maximum at 524 mμ, $\sigma = \pm 7$ mμ, and another maximum also at 345 mμ.

Statistical treatment for the 491-mμ and 468-mμ peaks gave $P_{20} < 0\cdot0002$; for the 491-mμ and for the 524-mμ peaks, $P_{19} < 0\cdot0002$; for the 468-mμ and 524-mμ peaks, $P_{5} = 0\cdot0002$. Comparison of the maximum for the dorsal part at 489 mμ with the maximum for the ventral part at 491 mμ gives $P = 0\cdot8$. All maxima in the ultra-violet are very close to each other, with P between 0·48 and 0·66.

If one compares sensitivity curves of receptors belonging to the most common type with the 491-mμ maximum by setting the maximum at 491 mμ as 100 per cent amplitude, the curves follow one another with one exception; some of them have a hump or even a third peak at 616 mμ. If the elements are compared according to the absolute value of potential amplitudes, the following rule becomes clear: the lower the response of an element, the more significant becomes the hump at 616 mμ, and only elements with very feeble action potentials show a peak at 616 mμ. This observation shows that the red screening pigment does not absorb light of this wave-length, and in weakly illuminated elements the portion of scattered red light becomes much greater than the portion of light coming through the dioptric apparatus of the ommatidium. On the other hand, except in the case of weakly illuminated elements and in the far red, the screening pigments are not relevant to the shape of the sensitivity curves. It appears from these experiments that *Calliphora erythrocephala* has at least three visual receptors with different spectral sensitivities. All sensitivity curves have a uniform peak at 345 mμ. This corresponds very well to the rather stable position of the β-absorption in all derivatives of vertebrate visual pigments. The correct value of this wave-length may be the same in *Calliphora* and in vertebrates, because our measurements may have been affected by the quality of filters available. It may be assumed that the visual pigment of the most common type of visual cell in *Calliphora* is a retinene with the maximum absorption near 490 mμ. This pigment is already known to occur in insects[10].

All the cells in the upper part of the eye yielded only one uniform curve. This situation is similar to that in other insects, which have been found to have one part of the eye sensitive to colours and another part colour-blind; for example, *Periplaneta*[11], *Notonecta*[12], and *Libellula*[13]. The most common receptor in the ventral part functions like the dorsal one. The numerical relationship among green, blue and yellow-green receptors is 18 : 4 : 3. If the assumption is made that five of the seven visual cells within each ommatidium are green receptors, and, of the remaining two, one is a blue and the other a yellow-green receptor, the numerical relationship would come very close to that actually found.

A Potential Source of Error in the Hexobarbitone Sleeping-Time Test in Mice

RECENTLY, Bhide[1] directed attention to the effect of hydration on the hexobarbitone sleeping time of mice. We have been able to confirm this work and that of earlier workers with respect to the effects of hydration in mice[2], but it is not generally appreciated that dehydration, whether achieved by means of diuretic agents or deprivation of water for relatively short periods, has a significant effect on hexobarbitone sleeping time; these effects may lead to error in the screening of potential central nervous system depressants where these agents also have some diuretic or antidiuretic activity and where water supplies are accidentally removed from the animals for short periods.

We have found that a series of diuretic substances, mainly unrelated either chemically or in their mode of action, reduced hexobarbitone sleeping time in mice as did deprivation of water for relatively short periods.

Unfasted female albino mice weighing 17–20 gm. received hexobarbitone sodium 100 mgm./kgm. at different intervals after receiving a dose of diuretic. The interval at which maximum effect was obtained is the only one reported. Sleeping time was taken as the interval between the loss and the regaining of the righting reflex. All drugs were given by intraperitoneal route in a volume of 0·2 ml. distilled water per 20 gm. body-weight. The diuretics examined were acetazolamide ('Diamox sodium' 25 mgm./kgm. and 500 mgm./kgm.), sodium sulphate (100 mgm./kgm.), sodium chloride (200 mgm./kgm.), sodium bicarbonate (200 mgm./kgm.), ammonium chloride (10 mgm./kgm.) and injection of 'Mersalyl' B.P. (0·1 ml./kgm.). Control groups received 0·2 ml. of distilled water at an appropriate time-interval before the anæsthetic. Ten mice per group were used throughout.

The results in Table 1 show that all the diuretics used in these experiments significantly reduced the hexobarbitone sleeping time.

Before the administration of hexobarbitone in the water-deprivation experiments, the animals were deprived of water for varying intervals of time but they were not deprived of food. Table 2 shows the results of these experiments. Deprivation of water for 2½ hr. before the administration of the hexobarbitone has a highly significant effect on the sleeping time. Mice have a high turn-over rate of water, about five times that of man[3], and it is reasonable to conclude that they are very susceptible to dehydration whether occasioned by withdrawal of water supplies or by diuretics. A water load of 1·5 ml./kgm., when given intraperitoneally ½ hr. before the anæsthetic, significantly increased the sleeping time.

Table 1

Diuretic	Hours between administration of diuretic and hexobarbitone	Control sleeping time	Sleeping time after diuretic ± *S.E.*	Values of *P* (*t* test)
Acetazolamide, 25 mgm./kgm.	2·0	31·2 ± 3·2	13·4 ± 2·4	0·001
Acetazolamide, 500 mgm./kgm.	2·0	31·2 ± 3·2	10·3 ± 1·7	0·001
Ammonium chloride	3·0	30·1 ± 3·1	20·2 ± 1·8	0·05
Sodium chloride	2·0	26·7 ± 1·6	20·1 ± 1·1	0·01
Injection of 'Mersalyl'	5·0	26·7 ± 1·6	13·5 ± 1·1	0·001
Sodium bicarbonate	0·5	26·7 ± 1·6	18·3 ± 1·2	0·001
Sodium sulphate	2·0	26·7 ± 1·6	15·1 ± 1·7	0·001

Table 2

Hours between deprivation of water and administration of hexobarbitone	Control sleeping time	Sleeping time after water deprivation ± *S.E.*	Value of *P* (*t* test)
0·5	31·5 ± 2·1	27·9 ± 1·2	Not significant
2·5	31·5 ± 2·1	16·9 ± 1·8	0·001

HÆMATOLOGY

Stathmokinetic (Mitosis-inhibiting) Method for estimating Plasma Erythropoietic Hormone

ASSAY methods for estimating the erythropoietic activity of plasma samples usually involve the evaluation of altered hæmatological values in test animals, or the change in incorporation of radioiron into the red cells of test animals—usually rats with polycythæmia induced by transfusion. *In vitro* bone marrow techniques do not seem to be widely used.

This communication describes a method for assaying plasma extracts, the stimulating properties of which appear to be confined to erythroid cellular division as observed in the bone marrow of the intact rat.

Activated plasma was obtained by bleeding rabbits (2·5–3·5 kgm.), 10 ml./kgm. body-weight, for 3 consecutive days, to a hæmoglobin-level between 5 and 6 gm./100 ml. On the fourth day the animals were exsanguinated under nembutal anæsthesia and blood taken by aortic catheter was received into bottles containing heparin as anticoagulant. The cells were then centrifuged off at −3° C., and the plasma stored at 3° C. Samples were pooled and then extracted, using Lowy and Keighly's modification[1] of the method described by Borsook[2].

Adult Wistar rats, weighing 150–180 gm., from a closed colony were the recipient animals. No animal was used unless it had been in the laboratory for at least 4 days and more usually the period was more than a week.

Injections of plasma extract were made subcutaneously for 3 consecutive days. At 10 a.m. on the fourth day, 18 hr. after the last injection, a subcutaneous injection of colchicine, 0·05 mgm./100 gm. weight, was given. 5 hr. later the animals were killed, a femur removed, and marrow smears prepared. Duplicate smears prepared from each animal were air-dried, fixed in methyl alcohol and stained with May-Grunwald Giemsa stain.

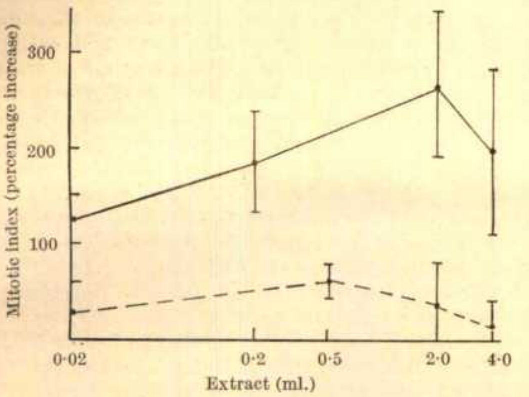

Fig. 1. Response of five groups of rats (4 or 5 rats in each group) injected with extract prepared from the plasma taken from bled rabbits. The interrupted line shows the response to extract from normal rabbit plasma

The films were examined under a high-power lens using oil immersion. Five hundred nucleated red cell precursors were counted, the number of mitotic divisions noted and the result expressed as a percentage (mitotic index). Red-cell precursors at all stages of development were counted, no attempt being made to differentiate between various stages of maturation. Cell differentiation was improved by the florid metaphase patterns resulting from colchicine blocking. A number of cells defied identification. The mitotic index of normal unstimulated animals receiving colchicine was estimated in 8 rats and the mean found to be $3 \cdot 8 \pm 1 \cdot 4$ *S.E.* All results were expressed as a percentage increase above this figure.

Fig. 1 shows a dose response curve using the method in groups of 4 or 5 rats. The interrupted line shows the response with extract prepared from plasma obtained from unbled rabbits. It is at once apparent that a very considerable increase in the mitotic index occurs with very small doses of the active extract. The fall in the response to the 4-ml. (active) dose is what one would expect in such a biological system. The rather sharp fall at 2- and 4-ml. doses for the extract from unbled animals suggests a tachyphylaxis which might result from antibody formation due to injection of relatively large quantities of protein-containing extract of low potency.

Grant[3] used colchicine to demonstrate its mitotic-inhibiting properties in bled rats, and in rats subjected to an atmosphere with low oxygen tension; my results are in accord with his findings.

The main advantage of the method appears to be its sensitivity in the lower dose-range—an advantage in striking contrast to other assay procedures. A major disadvantage is its lack of objectivity—a disadvantage partially removed by re-labelling the specimens by an independent observer, who disclosed the key only when the results were known.

Using this method, I have shown (unpublished work) that although mitotic erythroid hyperactivity is induced, the reticulocyte counts are not altered to a significant degree. Injections continued for 10 days did not produce changes in the hæmoglobin-level; this may mean that the factor necessary to cause this change was lacking, or alternatively that the potency of the material was low and that larger doses than those used (0·75 ml./100 gm.) might be effective. So far as these experiments have proceeded, the only effect has been on the rate of mitosis in the erythroid marrow cells.

It seems probable that this factor responsible for cellular division is identical with that demonstrated by others, for example, the ether-soluble fraction described by Linman, Bethell and their co-workers[4]. Further work is proceeding to characterize this factor.

Paracrystalline Hæmoglobin as a Species Difference between *Rattus norvegicus* and *Rattus rattus*

The common laboratory white rat is almost always the albino variety of the Norway rat (brown rat, *Rattus norvegicus*)[1,2] and only exceptionally the albino variety of the black rat (*Rattus rattus*)[3]. The two species are morphologically similar, which makes it rather difficult to distinguish them. Nevertheless, there are qualitative characters which make distinction sure.

On suspending the erythrocytes of albino rat in isotonic sodium citrate in a refrigerator their hæmoglobin attains a certain paracrystalline state characterized by general birefringence of these red cells in polarized light (Fig. 1) combined with enormously increased osmotic resistance[4].

Comparative studies showed that the red cells of the brown rat (*Rattus norvegicus*) only, be it the albino or the wild variety, sustain this change. It could not be observed, even after prolonged suspension, in the red cells of either the nearest zoological relative—the wild black rat (*Rattus rattus*)—or other animal species—white mouse, mouse (*Apodemus agrarius*), rabbit, hamster (*Cricetus cricetus, Mesocricetus auratus*), guinea pig, cat, dog, horse, pig, horned cattle, sheep and man.

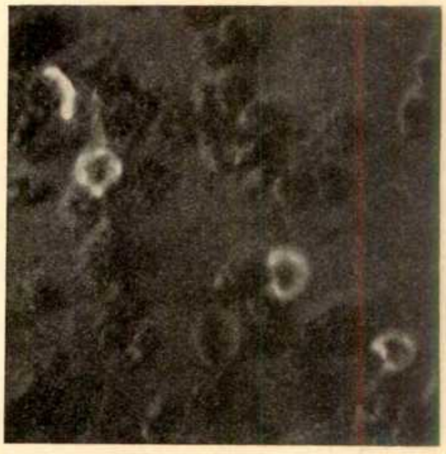

Fig. 1. Diffuse birefringence of paracrystalline red cells in the albino rat (*Rattus norvegicus*) in polarized light after 28 hr. storage in cold isotonic sodium citrate

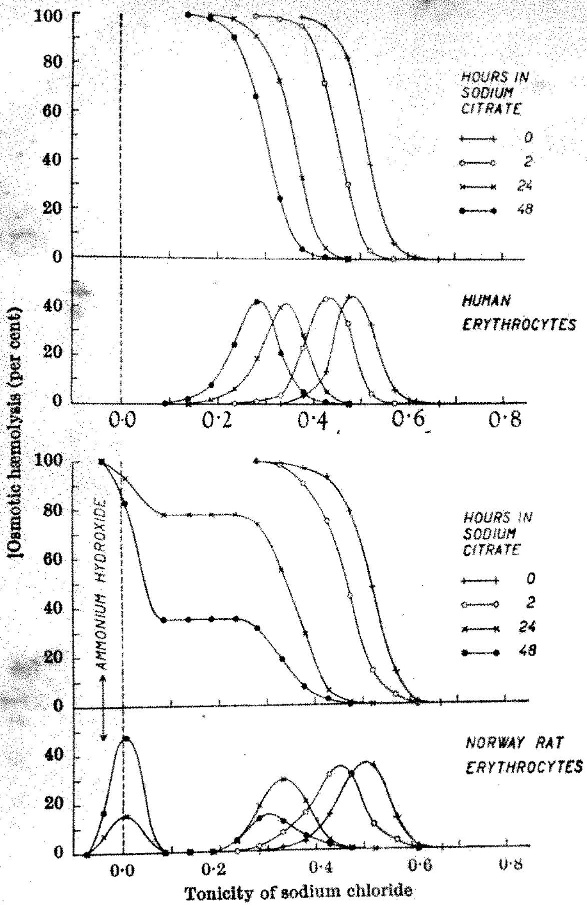

Fig. 2. Integral and distribution curves of osmotic resistance of human and albino rat (*Rattus norvegicus*) red cells during storage in cold isotonic sodium citrate

Similar differences between the erythrocytes of the Norway rat and other animal species were found in changes in osmotic resistance. The storage of erythrocytes in cold citrate is accompanied with gradual and marked increase of their osmotic resistance, especially in the first hours of suspension, and the maximum is attained within 60–72 hr. The increase is even in all red cells as evident from the Gauss-like type of the distribution curves[5]. All but the red cells of the Norway rat react thus, and even extremely resistant cells hæmolyse in distilled water (Fig. 2, upper part).

In contrast to that, the osmotic resistance of the red cells in the Norway rat changes in a different way, the cells being unevenly affected by cold citrate (Fig. 2, lower part): one part increases in resistance in roughly the same way as in other species, but the other attains resistance of such a degree that it withstands hæmolysis even in distilled water. The respective distribution curves are bimodal, reflecting a change of the originally homogeneous suspension into one with bimodal variability[6].

Two qualitatively different types of red cells thus exist side by side in the citrate suspension of brown rat red cells, the fraction of the paracrystalline birefringent and highly resistant erythrocytes being proportional to the duration of storage in the cold citrate.

The increase in resistance is due to change of colloid chemical properties of hæmoglobin proteins resulting from the escape of intracellular colloid water. The relation between mean corpuscular volume of the suspended red cells and the amount of their intracellular potassium and changes in concentration is an indirect proof of this.

The mean red cell volume decreases abruptly during the first 2 hr. of suspension in citrate through the escape of water while the absolute potassium quantity (μμgm. in one red cell) falls much slower. As a result, its osmotically effective concentration (expressed in m.equiv./l. of red cells) is higher than before storage. Red cells become more hypertonic than their environment and the initial decrease of their volume cannot be ascribed to loss of free water which only solves crystalloids but rather to water bound on colloids of the protein red cell core. Through this dehydration of intracellular proteins the red cells become more rigid and gel-like, only swell with difficulty and therefore show increased osmotic resistance.

Red cells with sodium for their main cation (sheep, cattle, cat)[7] and hence having still less possibility of decreasing their osmotically effective intracellular concentration in an environment rich in sodium react in the same way.

Dehydration of intracellular protein is so far advanced in some red cells of the Norway rat that the hæmoglobin molecules are forced, owing to lack of room, to arrange themselves into a paracrystalline birefringent space system. The structural orderliness and rigidity of these cells are so great that the cells withstand hæmolysis even in distilled water, being unable to swell sufficiently.

The birefringence described and variability of bimodal osmotic resistance in the Norway rat were found in both common laboratory white rat strains and inbred Wistar, *LE*, *PVG* and *WAG* strains. This supports the suggestion that all commonly kept laboratory rats belong to the Norway rat species, not to the black rat (*Rattus rattus*) species.

PATHOLOGY

Zymograms in Human Pathology

ENZYME histochemistry is sometimes a valuable aid in differentiating tumours in human pathology[1] and in studying several other pathological processes[2].

The methods used in histochemistry are based on the localization of enzyme activity. The action of the enzyme is demonstrated, not the enzyme as such. Moreover, in principle, it is possible to demonstrate any enzyme as a 'substance'. The method of Hunter and Market[3,4], in which tissue homogenates are

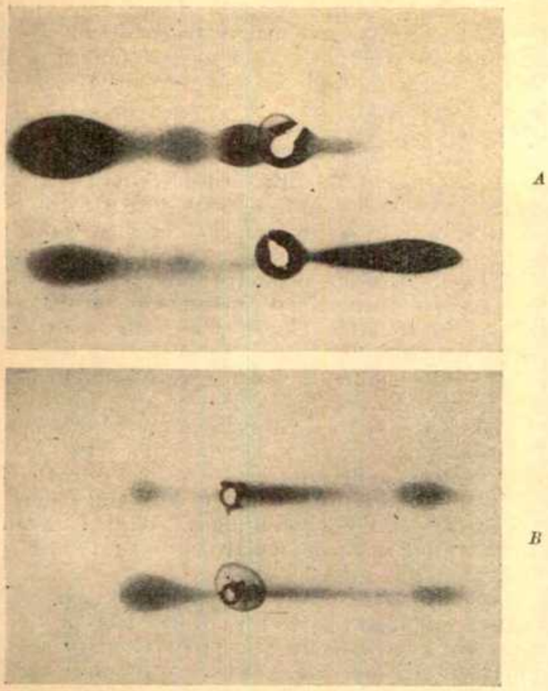

Fig. 1. *A*, Zymogram of homogenate of nodular goitre (upper) and of an adenocarcinoma of the large intestine (lower); *B*, amidoschwarz stained electrophoretic diagrams of the same homogenates ('albumin' moving to the right)

differentiated by means of starch-gel electrophoresis after which the enzymes are stained in the electrophoresis diagram according to a technique derived from histochemistry, offers a possibility of combination of characterizations. The histochemical technique employed locates the action of the enzyme; the position on the electrophoresis diagram more or less characterizes the enzyme as a protein. With the aid of this technique, Market and Hunter[4] succeeded in demonstrating various esterases in homogenates of organs of the mouse. The pictures obtained, indicating the localization of enzymes in the electrophoresis diagram, are called zymograms.

We used a somewhat modified and rather simpler technique, namely, agar electrophoresis[5], followed by histochemical location of the enzyme esterase in various anomalies in human pathology.

Histochemical slides (2·5 × 7·5 cm.) are immersed in 1 per cent agar solution and dried. Next 3 ml. of 1·5 per cent agar solution in veronal buffer pH 8·6 is poured on the slides. Beforehand, strips of electrophoresis paper are attached to the ends of the slides by means of buffer. These are hung in the electrode trays. With an injection needle, straight holes are punched in the agar which are filled with homogenate. This is prepared by homogenizing tissue in a Bühler apparatus with equal volume of distilled water. After electrophoresis (4 hr., 5 V./cm.) the electrophoresis slides are stained for 0·5 hr. by Gomori's esterase method[6]. The substrate is prepared by adding 1 ml. of 1 per cent α-naphthol acetate in 50 per cent acetone and 5 ml. of 0·2 M disodium hydrogen phosphate to 50 ml. of distilled water. In it some fast blue salt *RR* or *B* is dissolved. After incubation it is washed in distilled water, followed by overnight fixation in ethanol 50 per cent. After drying at 37° C. (glasses covered with filter paper) it is covered with cover-glass and glycerin gelatin. Other glasses are stained for protein after electrophoresis by means of amidoschwarz.

Fresh human material, mostly obtained by operation, was prepared in this manner. Several anomalies in various organs could be studied. Also in human material the zymograms thus obtained show distinctly different esterases. Fig. 1 gives an illustration. In Fig. 2 a few zymograms of anomalies in the digestive tract, thyroid gland and pulmonary tumours are grouped schematically. These illustrations are representative of what was observed in larger material. With our technique, in the main, 6 esterases are encountered in human material (I, II, III, IV, V, VI). Three of these (I, II, III) move in the direction of the albumin from the blood, the other three in the direction of the globulins.

Some general conclusions may already be drawn from our observations. It appears that different organs do not show the same zymogram. There are qualitative differences, for example, in the homogenates of the thyroid gland, the I and II esterases are lacking, and quantitative differences, for example, the predominance of I esterase in the digestive tract. Histochemically the highest esterase activity in thyroid gland, digestive tract and lung carcinoma was localized in the epithelium. The zymograms show highest activity of VI, I and II esterase respectively. The question arises whether electrophoretically different esterases show characteristic sites of localization. Further, it is noteworthy how the tumours of a single organ (lung carcinoma) show a fairly identical pattern. An adenocarcinoma of the appendix is clearly different from it. This displays a pattern similar to some non-tumour-like anomalies of the digestive tract.

Protein staining of the electrophoresis slides naturally shows a pattern quite different from the zymogram. It is noteworthy that protein is often scarcely demonstrable at the site of highest enzymatic activity (Fig. 1). This opens up possibilities for isolation.

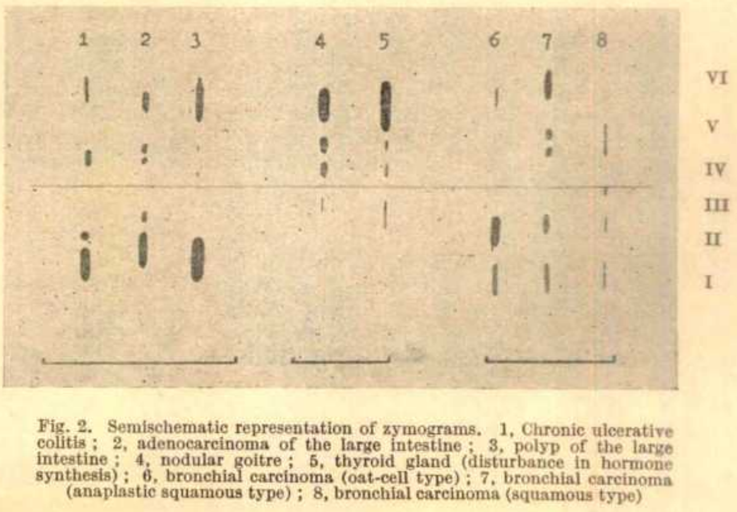

Fig. 2. Semischematic representation of zymograms. 1, Chronic ulcerative colitis; 2, adenocarcinoma of the large intestine; 3, polyp of the large intestine; 4, nodular goitre; 5, thyroid gland (disturbance in hormone synthesis); 6, bronchial carcinoma (oat-cell type); 7, bronchial carcinoma (anaplastic squamous type); 8, bronchial carcinoma (squamous type)

In principle the method employed is also suitable for other enzymes. It has already been applied by us in the case of acid phosphatase, for example.

A Heteroglycan from *Toxoplasma gondii*

LITTLE is known about the biochemical determinants of virulence and antigenicity in Protozoa. So far as we are aware, no immunochemical studies on *Toxoplasma gondii* have yet been reported, except the work of Hook and Faber[1]. They showed that cytoplasm-modifying and complement-fixing antibodies were related to the protein, but not carbohydrate fractions, obtained from sonically fragmented cells. Lunde and Jacobs[2] concluded that the *Toxoplasma* hæmagglutination test antigen was a protein contained in the crude lysate of washed parasites; but no attempts were made to isolate and identify the soluble antigens in a relatively pure state.

During the course of our comprehensive investigations on the immunochemistry of this protozoan species, we happened to isolate and study a polysaccharide fraction with special reference to its immunobiological properties, which are described in the present communication. The *RH* strain of *T. gondii* used was obtained from Dr. Leon Jacobs, National Institutes of Health, Bethesda, Maryland, and has been maintained by serial passage in mice, using peritoneal exudate. Pure suspensions were prepared from artificially infected laboratory-bred, serologically negative Swiss albino mice, using the method of Fulton and Spooner[3], and, on an average, each yielded 2×10^7 toxoplasms. Suspensions containing 20 mgm./ml. dry weight toxoplasmata were lysed by the addition of 10 times their weight of cold (4° C.) distilled water. After centrifugation and restoration of isotonicity by addition of an equal volume of 1·7 per cent sodium chloride solution, the carbohydrate fraction was separated by fractional precipitation with cold *iso*propanol, and deproteinization was carried out with chloroform and *n*-butanol. The actual yield of polysaccharide ranged from 2·8 to 4·2 per cent, with a mean value of 3·6.

Chemical analysis showed some unusual features, the nitrogen content varying from 0·8 to 1·2 per cent, and phosphorus from 0·2 to 0·4 per cent. No lipid could be detected on degradation with dilute acetic acid. The carbohydrate fraction was readily soluble and physical homogeneity was demonstrated by electrophoretic and ultracentrifugation techniques, and the absence of protein was confirmed by low nitrogen content, lack of ultra-violet absorption in the region of 280–290 mμ and failure of products to give the usual protein reactions. No nucleic acid could be detected by examination of their ultraviolet absorption spectra.

Agar-diffusion[4] experiments demonstrated immunological homogeneity when pure polysaccharide antisera reacted with homologous fractions and proliferative cell suspensions to give only one line of precipitation. When similar fractions obtained from ten other strains of *T. gondii* were examined in the gel-diffusion test, the lines that developed indicated identical specificity since they were, in every case, contiguous when reacting from adjacent reservoirs. No reaction was evident when antiserum against *Besnoitia jellisoni* (kindly furnished by Dr. J. K. Frenkel, University of Kansas Medical Centre) was tested against these preparations, or vice versa.

Chromatographic analysis revealed the presence of glucose, glucosamine and a rare pentose which could not be identified with reagents at our disposal. The presence of these sugars was confirmed by the corresponding precipitation inhibition tests on Ouchterlony double-diffusion plates. No aldoheptoses were found, and there is suggestion that the diffuse streaks on the stained chromatograms may refer to some of the newly discovered dideoxy sugars; this point is under examination in Prof. Dr. O. Westphal's laboratory at the Dr. A. Wander Forschungsinstitut, Freiburg–Zahringen, West Germany. Tests for uronic acid and reactive acetyl gave negative results.

The polysaccharide was a poor antigen when isolated, but high-titred antisera could be produced in rabbits by combining the preparations with the lipoprotein of *Shigella dysenteriae*, or by injecting the polysaccharide after coating on erythrocytes or on killed group *A* hæmolytic streptococci.

The polysaccharide sensitized sheep erythrocytes to agglutination, and lysis (120 μgm./ml.), and the specificity of the reaction was demonstrated in the corresponding inhibition tests. The fraction possessed no pyrogenic, skin-sensitizing or toxic activity, and after treatment with heat or alkali no alteration in these properties was detected. All the preparations fixed complement, did not interfere with the cytoplasm-modifying reaction, became coated on collodion particles (rendering them specifically agglutinable), inactivated the properdin system *in vitro*, had antiphagocytic and virulence-enhancing activity and acted both as a preparing and shocking reagent in the elicitation of generalized Schwartzmann reaction in rabbits.

Studies on its topographic distribution on intact cells of *T. gondii* indicated that it is at least a partial surface antigen. Resting cell-suspensions of *T. gondii* failed to oxidize the polysaccharide, which could not deplete the dye-test or complement-fixing activity of whole-cell antisera. In all cases, the polysaccharides, derived from as many as eleven strains that were examined so far, stimulated non-specific immunity to an extent approaching that induced by *Escherichia coli*, 2380, when tested by the method of Rowley[5].

The polysaccharide specimens could neither actively immunize mice to artificial infection with *T. gondii* nor did their corresponding antisera possess any passive mouse-protective power. Besides, all the preparations were found to lack (1) Forssman heterophile reactivity; (2) direct hæmagglutinating capacity; (3) capacity to inhibit lysozyme *in vitro*; and (4) ability to interfere with hæmagglutination of fowl erythrocytes by Newcastle disease virus. No heterogenetic relationship could be demonstrated between these soluble antigens and many species of bacteria that were included in this work.

No serological cross-reactivity was found between polysaccharide antisera and carbohydrates of known monosaccharide composition and linkage, such as synthetic polyglucoses with 1–4, 1–6 and 1–4–6 linkages, glycogens with 1–4–6 branching points, gum arabic and rhamnose-containing polysaccharides such as Karaya gum.

A comparative investigation is in progress to delineate the role of this antigenic fraction in infection and immunity. A detailed account of these results will be published elsewhere.

We are indebted to Dr. T. Ramakrishnan, Indian Institute of Science, Bangalore, who carried out the physical examination of the polysaccharide fraction.

BIOLOGY

Electron Microscopy of Mossy Fibre Endings in Ammon's Horn

The endings of the axons of the granule cells of the dentate fascia in relation to Lorente de Nó's areas *CA*3 and *CA*4[1] of Ammon's horn have certain special morphological characteristics as seen in Golgi preparations. These have been described by Cajal[2], who termed them mossy fibres, analogous to those of the cerebellum. He found that these axons have a tortuous course and that they show characteristic varicosities consisting of triangular or star-shaped masses of protoplasm, from the angles of which both short and long processes arise. The main course of this dentate-ammonic tract runs across the bases of the apical dendrites of *CA*4 and *CA*3 neurons at right angles to them. The protoplasmic masses come into intimate contact with the apical dendrite or occasionally with the neuronal perikaryon, and were considered by Cajal to be sites of synaptic contact. Lorente de Nó[1] was also of this opinion, but could not decide whether the structures were part of the pyramidal neuron or of the axon terminating on it. According to Cajal[2] these 'mossy endings' could not be stained by reduced silver techniques.

Electron microscopy shows that these structures are large presynaptic bags into which dendritic spines, sometimes branched, are invaginated.

Appropriate regions of the hippocampus of the rabbit were fixed with buffered osmium tetroxide, stained with alcoholic phosphotungstic acid and embedded in araldite for sectioning[3].

Sections through the apical dendrites near their bases show the presence of structures having the characteristics of presynaptic processes, but which have diameters of 3–4μ (Fig. 1, *pre*). These large bags are full of synaptic vesicles, and the enclosing membrane may be seen to be in close contact with the apical dendritic membrane for distances of up to 4μ. The opposed membranes are thickened at intervals (*b*), such thickenings having the appearance of synaptic contacts as described by previous authors[3].

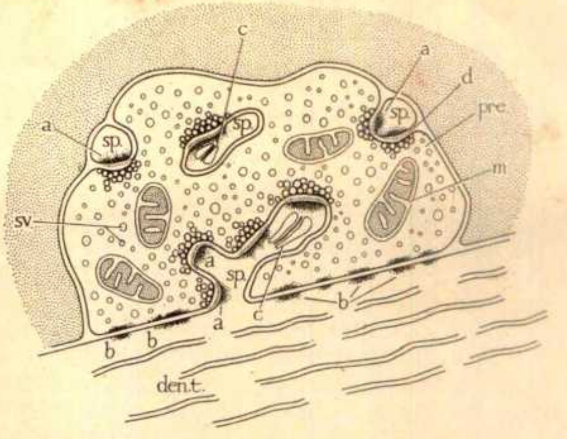

Fig. 1. Diagram of a presynaptic bag showing areas of synaptic contact with dendritic spines and with the main dendrite. The stippled regions represent neuronal and glial processes of the neuropil

In addition, the profiles of several dendritic spines (*sp*) may be seen within the bag, and in favourable planes of section continuity of these with the main dendrite can be observed. Such dendritic spines may be branched. The tubules of the main dendrite (*den. t.*) do not appear to enter these spines. Identification of these small dendritic profiles (diameter is usually 0·5–1μ) depends on the presence in many cases of a spine apparatus (*c*) similar to that which has been described in neurons of the visual cortex of the rat[3]. Also, the membranes of the spine show numerous synaptic contacts (*a*), in which the thickening of the post-synaptic membrane is wider and denser than that of the presynaptic membrane, with, in addition, widening of the intermembranous space (~300 Å.) in the region of the synaptic area. These appearances are in contrast to those of the synaptic contacts between the presynaptic bag and the main dendrite (*b*), where the thickenings of the two membranes are equal and there is no increase in width of the space (~200 Å.) between the pre- and post-synaptic membranes. These two varieties of synaptic contact thus correspond to the types 1 and 2 described by Gray[3] in the visual cortex of the rat.

It is of interest that in this situation a single presynaptic bag may be observed to form two types of synaptic contact, suggesting that the differences may be due to variations in the properties of the post-synaptic processes rather than in the nature of the axonal ending. Observations of Golgi preparations[2] with the light microscope show that these synaptic structures are in many cases not terminal, but of the 'bouton de passage' type. It has not been possible so far to verify this point in electron-micrographs, owing to the difficulty of obtaining a suitable plane of section. As well as the synaptic vesicles, the presynaptic bags may be seen to contain from three to six mitochondria, but in no case have neurofilaments been observed. The absence of neurofilaments may explain the fact that these endings do not stain with reduced silver techniques, as the argentophilia which is found in the axonal terminals of certain regions appears to depend on neuro-filaments being present[4].

A full report of this work will be published at a later date.

I am indebted to Dr. E. G. Gray and Prof. J. Z. Young for their interest and advice.

Juvenile Stages of *Fasciola hepatica* in the Liver of the Mouse

MOST biologists agree that in the later stages of its life-cycle *Fasciola hepatica* wanders through the liver towards the bile ducts, where maturity is attained. When cysts containing metacercariæ are ingested along with herbage to which they are attached, the larvæ are activated in the intestines of the host and are then able to emerge from the cysts, each of which develops a minute perforation. The young flukes then penetrate the wall of the intestines, creep about over the abdominal viscera and eventually enter the liver. Much research and some controversy were necessary before this migration became established beyond any doubt. Schumacher[1] has reviewed the literature bearing on this problem, and himself carried out experiments of a classical nature, which produced much valuable information concerning the time relations of the various stages of the migration in guinea pigs. He also gave an account[2] of the histological appearance of young flukes in the liver of the host 64 hr. after cysts were fed, but this is a very incomplete study and practically no other information of the same kind is available in the literature of fascioliasis. I have studied the early stages of migration through the liver of the definitive host, the mouse having been chosen to minimize the rather laborious task of serializing sections of infected liver.

The young flukes assemble in the abdominal cavity of the mouse about 24 hr. after cysts are administered *per os*, and during the next 2 days some of them enter the liver. At this stage, they are about 0·3 mm. long, but growth is so rapid that the length is about 0·5 mm. in 6 days, 0·6 mm. in 7 days, 0·8 mm. in 8 days and 1·2–1·6 mm. in 11 days. During little more than 1 week spent in the liver, therefore, the young fluke quadruples its length, at the expense of hepatic tissue. The burrow of the entering fluke is only a little broader than its body, but it is equal to about six hepatic cells in breadth, so that by the time the body of the fluke is just accommodated several hundred hepatic cells have been damaged and excavated. As the fluke grows, the burrow becomes progressively larger, and as the liver may be riddled with burrows, in even moderate infections, the toll of hepatic tissue must become truly enormous. Two photomicrographs of this damage and also the mode of progression of the young flukes are reproduced here (Fig. 1). Four days after the feeding of cysts, the young fluke may be seen advancing into a mass of hepatic cells (Fig. 1,*A*). Pyknotic nuclei of hepatic and reticulo-endothelial cells, and some cytoplasm, form a wedge-shaped mass which is entering the oral sucker. Damaged hepatic tissue is seen in the wall of the burrow and a mass of debris, largely nuclear but also containing leucocytes and erythrocytes, occurs in the wake of the fluke. This appearance is characteristic. The fluke advances into normal tissue, effectively devouring it, and broken tissue which is not ingested forms a concentrate, largely of nuclear origin, which is smoothed down by the movements of the fluke and eventually left behind in the most recently vacated part of the burrow. The burrowing fluke moves along a slightly zig-zag path, the direction of advance changing slightly from time to time, and the older burrow thus assumes the appearance of a number of ovoid chambers with narrower connexions. Change of direction is indicated by slight compression of the hepatic tissue on the right of the fluke seen in sagittal section in Fig. 1, *B* ; this fluke, which is at the 8-day stage, illustrates the way in which the rim of the oral sucker, beak-like in section, bites into masses of hepatic cells, and the anterior end of the fluke is flexed ventrally in a characteristic feeding posture.

The importance of studying the feeding activities of such young flukes will be obvious to helminthologists, who are well aware that such flukes are able to resist the action of any drugs which have so far proved successful for the destruction of adult flukes residing in the bile ducts. A fuller account of the early stages of migration through the liver is now published[3], and in this an attempt has been made to demonstrate the preference which young flukes seem to have for a

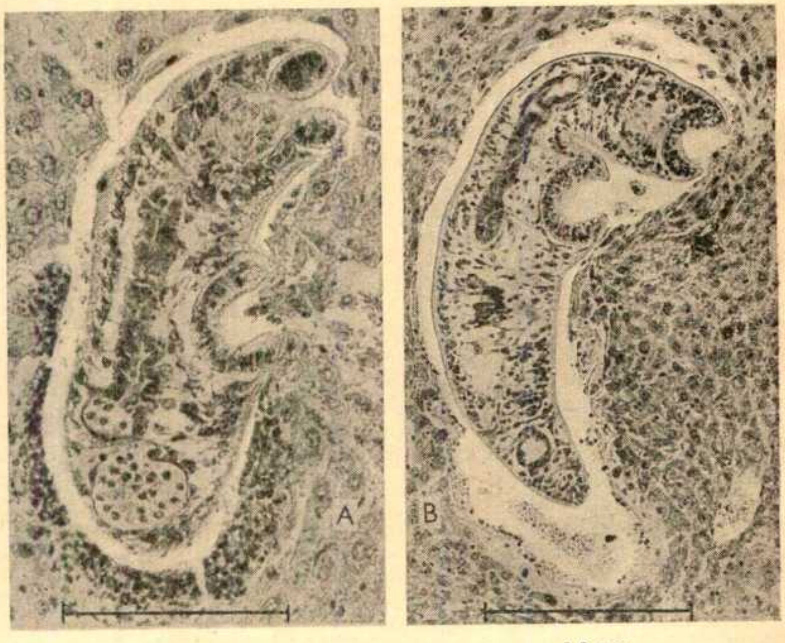

Fig. 1. Sagittal sections passing through two young flukes in the liver. In *A*, 4-day stage, note damaged tissue in the wall of the burrow, hepatic cells with pyknotic nuclei about to be ingested, and debris accumulating in the rear of the fluke. In *B*, 8-day stage, note a characteristic feeding posture, oral sucker approaching hepatic cells, and change of direction of burrowing indicated by compression of hepatic tissue

diet of hepatic cells. It is inevitable that damage to a vascular organ such as the liver should produce hæmorrhages, but in these early stages it is seen that much of the blood which seeps into the burrows lodges in the regions vacated by the flukes, which ever seem to seek fresh hepatic cells. It is claimed that the young fluke is never a blood-feeder in the accepted sense of the term, showing a distinct preference for the hepatic cells, which must form a succulent diet.

Biochemical Indications as a means of distinguishing between Iron and Manganese Deficiency Symptoms in Citrus Plants

IRON and manganese deficiencies are widespread in many citrus-growing areas throughout the world, including Israel. Similarity of the visual symptoms of these deficiencies, in some stages (Fig. 1), makes differentiation difficult[1].

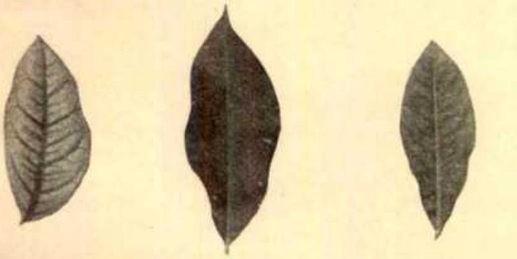

Fig. 1. Control (centre) and manganese- (left) and iron- (right) deficient lemon leaves

Moreover, due to the rather wide range of leaf patterns associated with manganese insufficiency, there are contradictory descriptions of these symptoms in the literature[1-3]. Since it is assumed that the visible symptoms are, in some way, an expression of the disturbed metabolic processes in plant cells, it was decided to investigate these metabolic pathways in order to throw some light on the reasons for this visual similarity. Different metabolic patterns, however, may be used as reliable indicators in differentiating between iron and manganese deficiency symptoms.

This communication deals with only a part of the different metabolic patterns that were observed.

For the purpose of the experiment, several varieties of 3-month-old citrus seedlings—rough lemon, sweet lime and sour orange (generally used as root-stocks) and Shamouti orange, Duncan grape fruit, and Eureka lemon (used as scions)—were transferred to aerated water culture and were grown in a green-house. Purification and composition of the nutrients were according to Hewitt[4].

The solutions contained gradually decreasing amounts of iron and manganese and were changed every fortnight. Characteristic deficiency symptoms developed after 3–6 months. Leaf samples were taken from the plants exhibiting different stages of the developing visual symptoms, especially when iron and manganese deficiencies could be confused.

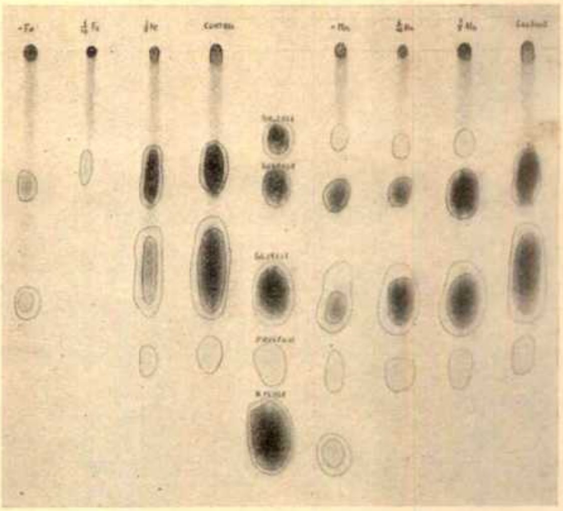

Fig. 2. Ascending paper chromatograph (butanol/acetic acid/water, 9 : 1 : 3) of lemon leaves extract from plants supplied with decreasing amounts of iron and manganese, compared with the markers (in the centre). Spots developed by anilin/butanol/phosphoric acid/water (1 : 5 : 1·2 : 10) spray

Five gm. of fresh leaf material were macerated in 80 per cent ethanol, the ethanol was evaporated *in vacuo*, and the solution was passed through 'Zeokarb 225' and 'Deacidite *G*' resin columns which retained amino-acids and organic acids respectively. The solution, after passage, contained sugars which were detected by means of paper chromatography[5].

Fig. 2 clearly shows the degradation of sugars, due to decreasing amounts of iron in the nutrient solution, and the appearance of some free pentose in the case of manganese-deficient lemon plants.

Since pentoses can be more rapidly detected by methods other than chromatography, it was decided to do so by means of an orcinol test, which can be used as a simple colorimetric determination[5].

For this purpose 0·5 gm. of fresh leaf material was macerated in water and acetone, and besides the pentoses, the peroxidase activity and the chlorophyll content of the sample were estimated[6]. Chlorophyll serves as a means of indicating degree of chlorosis, and peroxidase activity has been found to vary, according to different micronutrient deficiencies, in tomato plants[7].

After centrifugation the supernatant was purified by active carbon and 'Zeokarb 225', and the colourless plant sap was used for the orcinol reaction[5].

Table 1 shows that, in addition to free pentose accumulation, which is enhanced by manganese deficiency, peroxidase activity and chlorophyll $a : b$ ratio may give some substantial contribution to the problem of rapid and correct evaluation of this type of deficiency symptom. This 'biochemical approach' should be appraised in the light of other diagnostic methods, namely, visual symptoms, mineral analysis of the leaves and different methods of diagnostic supply of minerals to deficient leaves.

Chemical analyses of leaves for iron and manganese are not only troublesome in comparison with these tests, but also do not always give a conclusive answer; for example, it has been found[2] that when manganese is deficient, in many cases, less iron also appears to accumulate in the leaves. Diagnostic sprays consume considerable time and, sometimes due to impurities

Oxidation of Reduced Pyridine Nucleotides and of Sulphite by Pea Root Mitochondria

IT has been shown[1] that freshly isolated pea root mitochondria oxidize α-oxoglutarate poorly or not at all if the oxygen uptake is measured by a polarographic method (in which the mitochondria are not shaken), and the oxygen uptake is not stimulated by diphosphopyridine nucleotide (oxidized form, DPN). However, if the mitochondria are first shaken for 30 min. in a water bath at 25°, they do oxidize α-oxoglutarate and DPN increases the rate of oxygen uptake (Table 1).

The ability of these mitochondrial preparations to oxidize the reduced pyridine nucleotides has been examined by the same procedures. At a low concentration (0·1 m*M*) reduced diphosphopyridine nucleotide (DPNH) was not oxidized by unshaken, but was by shaken, mitochondria (Table 2, exp. 1). This suggests that shaking makes the mitochondrial membrane more permeable to DPNH. With reduced triphosphopyridine nucleotide (TPNH), however, the oxygen uptakes were about the same for both unshaken and shaken mitochondria (Table 2, exp. 2), thus indicating, perhaps, that the membrane of the unshaken mitochondrion is already permeable to TPNH (but not to DPNH). In this respect pea root mitochondria are similar to rat liver mitochondria[2].

Table 1. OXIDATION OF α-OXOGLUTARATE

Additions	q_{O_2} Unshaken mitochondria	Shaken mitochondria
None	450	350
DPN (0·1 m*M*)	460	350
α-Oxoglutarate (10 m*M*)	440	660
DPN (0·1 m*M*) + α-oxoglutarate (10 m*M*)	440	790

The incubation medium contained 0·05 *M* phosphate buffer, *p*H 6·8, 10 μ*M* cytochrome *c*, 100 μl. mitochondrial suspension and additions as given in the Tables, in a total volume of 0·5 ml. Experiments were conducted at room temperature (22–23° C.). Oxygen uptake (measured polarographically) is expressed as q_{O_2} (μl. O_2/mgm. trichloroacetic acid—insoluble N/hr.).

Table 2. OXIDATION OF REDUCED PYRIDINE NUCLEOTIDES

Exp.	Additions	q_{O_2} Unshaken mitochondria	Shaken mitochondria
1	None	500	500
	DPNH (0·1 m*M*)	510	740
2	None	530	560
	TPNH (0·1 m*M*)	630	680
	TPNH (0·7 m*M*)	740	780
3	None	520	490
	DPNH (5 m*M*)	2,110	1,610
	TPNH (5 m*M*)	1,430	890

At much higher concentrations (5 m*M*), both DPNH and TPNH were oxidized by unshaken mitochondria (Table 2, exp. 3). They were also oxidized by shaken mitochondria, but at a much slower rate. At a concentration of 1·0 m*M*, DPN enhanced the low oxidation of α-oxoglutarate by unshaken mitochondria[1] whereas there was no enhancement at a concentration of 0·1 m*M* (Table 1). It thus seems that at external concentrations of 1·0 m*M* and more, the nucleotides can enter the mitochondria.

Table 3. OXIDATION OF SULPHITE

Exp.	Additions	q_{O_2} Unshaken mitochondria	Shaken mitochondria
1	None	500	430
	ADP (m*M*)	510	440
	Na_2SO_3 (0·3 m*M*)	500	580
	ADP (m*M*) + Na_2SO_3 (0·3 m*M*)	500	660
2	None	400	410
	DPN (0·1 m*M*)	400	400
	Na_2SO_3 (0·3 m*M*)	410	560
	DPN (0·1 m*M*) + Na_2SO_3 (0·3 m*M*)	420	560

Sulphite is oxidized by mitochondrial preparations from pea internodes[3] and oat seedlings[4]. It is also oxidized by pea root mitochondria, but only if these were first shaken (Table 3). Adenosine diphosphate (ADP) increased the uptake of oxygen in the presence of sulphite only with shaken mitochondria and DPN had no effect on this uptake. This supports the finding[3,4] that ADP, but not DPN, is required by the sulphite-oxidizing system.

Growth of *Fomes annosus* under Reduced Oxygen Pressure and the Effect of Carbon Dioxide

Although most fungi are regarded as strictly aerobic organisms, some species—under natural conditions—are known to colonize in localities which *a priori* must be expected to offer only poor supplies of free oxygen. This is the case with fungi attacking the interior of roots and stems of living trees. Owing to respiration in the living tissues of these organs, free oxygen dissolved in the water of vessels in sapwood and heartwood or present as free gas in intercellular spaces and non-functioning vessels is soon consumed. Concomitantly carbon dioxide is liberated. Diffusion of gases within a tree trunk probably occurs by the shortest distance, namely, by horizontal diffusion from the outside through the cortex into the interior of the stem and vice versa. However, in warm seasons when respiration-rate is high the very active cambium enclosing the central wood of a stem offers a barrier to the diffusion of gases in either direction[1]. Consequently as oxygen is consumed by living cells (medullary ray cells, parenchyma cells) in the sapwood the oxygen pressure will drop rapidly in the interior and be kept at a low level until diffusion is again made possible by a decrease in temperature.

Seasonal variation in oxygen and carbon dioxide pressures in stems of several hardwood and softwood trees has been investigated by Chase[2], who found that in summer the oxygen content in the wood of *Pinus strobus* would drop to approximately 1 per cent, corresponding to a pressure of 8 mm. mercury. At the same time the carbon dioxide content increased to approximately 10 per cent.

The parasitic basidiomycete *Fomes annosus* (Fr.) Cke. is known to attack roots and heartwood of many conifers and even deciduous trees, thus being exposed periodically to conditions of low oxygen pressure and high carbon dioxide pressure. It was, therefore, of interest to investigate the growth response of this fungus to such conditions.

Round 6-mm. pieces from the periphery of a young colony of *F. annosus* on malt agar were inoculated on to the surface of freshly boiled and poured malt agar in Petri dishes and incubated at room temperature in Brewer jars containing air, hydrogen, nitrogen and/or carbon dioxide. In the hydrogen jars all free oxygen and oxygen dissolved in the agar was removed by catalytic reaction with the hydrogen, the jars thus representing a strict anaerobic environment. No growth occurred in these jars (Table 1). In the nitrogen jars the oxygen was removed by three subsequent evacuations to 40 mm. mercury and slow refillings with nitrogen which had passed through a wash bottle containing alcalic pyrogallol. Theoretically the nitrogen jars contained only 0·02 mm. oxygen although the actual content might have been somewhat higher because of sluggishness in oxygen diffusion from the agar. Nevertheless, these bottles represented a micro-aerophilic environment in which *F. annosus* proved to grow unaffected.

Table 1. Growth of *Fomes annosus* on Malt Agar in Air, Nitrogen, Hydrogen and Carbon Dioxide. Total Pressure 760 mm. Mercury. Incubation 6 days at Room Temperature

Gas pressure (mm. mercury) Q_2	N_2	H_2	CO_2	Linear growth (mm.)	
160	600	0	0·228	30	Atmospheric air
155	582	0	23	44	Carbon dioxide added to air
0	trace	760	(trace)	0	
0	trace	737	23	0	
trace	760	0	(trace)	30	
trace	737	0	23	45	

For growth in pure carbon dioxide the jars were filled in the same way as with nitrogen except that the washing in pyrogallol was omitted. These jars also represented a micro-aerophilic milieu. With 760 mm. carbon dioxide no growth occurred whereas 23 mm. of the gas in combination with air or nitrogen accelerated growth about 50 per cent. As could be expected, no effect was obtained under strictly anaerobic conditions in hydrogen.

That neither hydrogen nor carbon dioxide in high concentration *per se* was toxic to *F. annosus* was shown by subsequent aerobic incubation at which normal growth was resumed.

Nine different strains of *F. annosus* (isolated from fruiting bodies on infected *Pinus sylvestris* and *Picea abies*) have responded qualitatively equal to those conditions. It could be concluded that *F. annosus* is a fungus able to grow equally well under aerobic as under microaerophilic conditions, but not anaerobically, and that a slight elevation of the carbon dioxide pressure has a stimulatory effect, but a high concentration of this gas an inhibitory effect on mycelial growth. These observations seem to agree well with what was to be expected from a fungus parasitizing the interior of roots and trunks.

Filtration of Phytoplankton by the Octocoral *Alcyonium digitatum* L.

Most of the work carried out on the food and feeding of cœlenterates deals with the true reef-building corals, Actiniae and Scyphomedusae, which harbour zooxanthellae in their tissues. The group Alcyonaria, however, has received less attention. There seems to be considerable controversy as concerns the significance of these symbiotic algae for their host-cœlenterates. Some authors report that the cœlenterates derive no benefit from their zooxanthellae[1,2], while others believe that zooxanthellae form a considerable part of their food, the other part being of animal origin[3–5]. Still others maintain that some cœlenterates, namely the xeniid octocorals, may in some way or other rely on their algae as their only source of food[6,7].

Little work has so far been done to study the food and feeding of alcyonarians which do not harbour zooxanthellae in their tissues, for example, *Alcyonium digitatum* L.[3,8], which has been described as carnivorous. Its food is reported to consist solely of other small animals, mainly zooplankton organisms, which it paralyses by the action of its nematocysts.

In order to investigate whether *A. digitatum* is fully dependent on animal food or may also feed on phytoplankton organisms, fresh colonies were placed in the dark in jars containing membrane-filtered sea water, to which strains of *Sceletonema costatum* labelled with carbon-14 were added. Two different concentrations of algae were used (20 : 1). The rate of removal of algae by the octocoral was estimated by measuring the radioactivity in sub-samples of 10 ml. water at time-intervals starting with half an hour. As a control, the drop in the radioactivity of the algae was measured in the same way in identical concentrations of *Sceletonema*. The considerable decrease (27 per cent) of activity in the control with the higher concentration of algae is probably due to the dense concentration of algae as well as to the bacterial activity (the *Sceletonema* strains used were not bacteria-free) (see Table 1).

Table 1. RADIOACTIVITY (C./MIN.) IN SUB-SAMPLES OF 10 ML. SEA-WATER

Lapse of time (hr. and min.)	Experimental (*A. digitatum*)		Control	
	Concentration of algae (20)	(1)	Concentration of algae (20)	(1)
0	687	45	666	34
0·30	—	34	—	—
1	674	—	—	—
2	—	17	—	—
3	533	25	—	29
4	—	65	—	—
5	492	—	592	32
6·30	496	23	—	—
23	250	—	486	36

In the higher concentration of algae, one colony of *A. digitatum* filtered about 50 per cent of the *Sceletonema* present in 23 hr. while in the lower concentration, another filtered up to 93 per cent of the algae in only 6½ hr. After the experiments, thoroughly washed pieces of the *Alcyonium* colonies were homogenized and the activities of the different parts measured (c./min.) were as follows: ectodermal covering, 4·7; mesoglœal and endodermal tissue, 22·7; and gastric juice, 46·5. In some other experiments still higher activities have been measured in the tissue-homogenates of *A. digitatum*[9]. In all the feeding experiments we have carried out using strains of *Sceletonema costatum*, *Ditylum* sp. or natural phytoplankton populations labelled with either carbon-14 or phosphorus-32, *A. digitatum* has proved to be able to filter such algal organisms.

The ability of *A. digitatum* to filter and obviously digest phytoplankton algae is evident from the above data, demonstrating the transportation of the labelled nutriment to different tissues of the colonial animal. This phenomenon may help to explain why this species can survive for relatively long periods of time in waters deficient in zooplankton, and moreover supports the idea that at least some cœlenterates may also feed on plant material.

The ciliary movements in *Alcyonaria* seem well suited to filter phytoplankton algae out of the surrounding water. In *A. digitatum* the ciliary current maintained in and out of the polyps seems not only to convey oxygen, as already stated[10], but will also constantly bring a new potential source of plant food within their reach. It might, of course, be expected that such a current would play no part in providing *A. digitatum* with its animal-food, since the latter mainly consists of small zooplankton crustaceans which move too fast to be caught by ciliary currents. In the active stage, however, *A. digitatum* expands greatly with a resulting enormous increase in the surface area[11] and this brings the colony in contact with a still larger volume of water masses. Moreover, as may also be expected, expansion and extension of the polyps activate the ciliary currents in their cœlentera. It is not believed, however, that expansion of the *Alcyonium* colony to its normal activity size is induced by any need of oxygen, provided that this gas is not deficient in the surrounding water[11]. It is almost certain that the expansion of the colony in Nature is related mainly to feeding requirements.

VIROLOGY

Inhibition by Cortisone of the Synthesis and Action of Interferon

THE administration of cortisone and certain other C-21 and 19-nor-steroids increases final yields of influenza virus in chick embryos by inhibition of viral interference[1]. Paradoxically, the rate of viral synthesis is reduced[2] at the same time. Interferon, a substance produced by cells inoculated with interfering virus, has been proposed as the mediator of interference[3]. Therefore, it was important to determine whether cortisone and other steroids capable of inhibiting the induction of interference might influence either the production of interferon or its effect.

We find that interferon is produced most easily by a method suggested by Wagner[4]; this involves the intra-allantoic inoculation of chick embryos with small amounts of infective virus and prolonged (65–72 hr.) incubation before harvesting allantoic fluid. After dialysis of allantoic fluid at pH 2·0, which destroys the virus but leaves interfering (interferon) activity, this activity is measured as the reduction in viral synthesis *in vitro* in chorioallantoic membrane cultures. It has been found that membranes of older (12–13 day) chick embryos are more susceptible to the interferon effect[5], and these have been used in the present experiments.

In Table 1 we present the summary of an experiment in which cortisone (diethylaminoacetate hydrochloride of hydrocortisone) in two dosages clearly prevented the *in ovo* synthesis of interferon. In this

Table 1. INHIBITION OF INTERFERON FORMATION BY CORTISONE

§ Log_2 viral hæmagglutinin.

+ Chorioallantoic membrane tissue culture.

experiment 11-day-old chick embryos (4/group) were inoculated with $10^{2\cdot0}$ EID_{50} of the *PR*8 strain of influenza *A* virus, or a saline control 2 hr. after the injection of water (control), cortisone, or *SC*-5914, 'Searle' (17-ethyl-19-nortestosterone), a steroid with 1/1,000 the activity (by weight) of cortisone in negating interference with inactivated virus (Kilbourne, E. D., unpublished results). After 70 hr. of incubation, allantoic fluid pools were collected from each group, then dialysed against 0·1 *M* sodium chloride glycine buffer at pH 2·0 for 24 hr. at 4° C. These 'interferon' preparations were then restored to pH 7·0 by dialysis against 0·01 *M* phosphate buffered saline for 24 hr. (two changes) (Table 1, part *A*).

As shown in part *B* of Table 1, the interferon activity of 1 : 2 dilutions of the pools thus treated was determined *in vitro* by inoculation of 12-day-old chorioallantoic membrane cultures with 10^6 EID_{50} of influenza *B* virus (Lee) 20 hr. after their incubation with 'interferon' pools or medium alone (group 6). Measurement of yields of hæmagglutinin 42 hr. later demonstrated reduced titres (evidence of interferon action) only in groups 1 and 2, which had not received cortisone originally. It has been established since then that cortisone does not merely prevent the release of interferon from the chorioallantoic membrane into the allantoic fluid, but also inhibits its formation in the membrane. The design of the foregoing experiment precludes the possibility that cortisone acted *in vitro* after interferon was synthesized, because dialysis separates effectively the (dialysable) steroid remaining in the allantoic fluid from the non-dialysable interferon.

However, it has been shown in other experiments that cortisone and other steroids administered *in vitro* will prevent the *effect* of pre-formed interferon if they are given 2 hr. before the inoculation of interferon, then removed by washing before the incubation of membranes with interferon and the subsequent inoculation of challenge virus. It is of interest that suppression of interferon action is the only biological action manifestly common to the disparate steroids capable of inhibiting interference.

Previous papers from this laboratory have suggested that inhibition of both viral synthesis and interference by cortisone might have a single biochemical basis[1], and that the basis was most probably related to the inhibiting effect of cortisone on protein synthesis[2]. It is, therefore, of great interest to find that cortisone inhibits the synthesis of a protein (interferon) which can interfere with virus replication. If interferon is an abortive product of viral multiplication[3], then further evidence is provided that the effects of cortisone on viral multiplication are on protein rather than nucleic acid synthesis.

It seems possible that endogenous adrenal corticoids may influence the dynamics and outcome of infection *in vivo*, depending on the balance of their effects on viral synthesis and on the synthesis and action of interferon.

This investigation was supported by a research grant *E*–1595 from the National Institutes of Health, Division of Allergy and Infectious Diseases, Public Health Service.

Apparent Release of Tobacco Mosaic Virus in Living Infected Cells

USING a Zeiss *GFL*65 phase microscope with 'Neofluar' objectives we are attempting to record the sequence of changes produced by tobacco mosaic in living cells of Turkish tobacco. Leaves at intervals after inoculation are prepared by exhausting them of air under water with a high-vacuum pump. Hand sections are cut in a pan of water under a binocular microscope with small pieces of razor blade mounted in a handle. Most sections are paradermal, along or beside veins on the underside of leaves inoculated with tobacco mosaic virus on the upper surface, or on systemically infected leaves. One cell thickness, sometimes obtainable, is ideal ; 2 cells may allow images that can be photographed, and occasional observations are possible on pieces 3 cells thick.

A number of tissue pieces have provided images, apparently of the primary emission of virus in recently infected cells. Strains *U*1 and *U*5 [1,2], representing 2 forms of the virus[3], initiated similar series of events, differing in several details. Appreciation of these events, when they were first seen to occur, was aided by previous studies on the state of cells after infection was apparent.

Tobacco mosaic virus aggregates in recently infected cells often appear as translucent monolayers in the parietal cytoplasm. Single or double layers are termed grey plates[4]. The long axes of the virus particles seem to be vertical to the cell wall, and aggregation is lateral. The grey plates vary in size from 1 to 5μ or more in diameter. If the virus is of the *U*1 form, several monolayers may appear over each other, remain attached, and become by accretion the familiar hexagonal crystals or thick virus plates. Virus of the *U*2–*U*5 form fails to aggregate into crystals, apparently because the end-to-end bonding of the particles is too weak to hold a number of monolayers together. Later, the virus particles of *U*2–*U*5 combine in crude acicular aggregates. A second difference between forms is the presence of

x-bodies in $U1$-infected cells, but not in $U2$–$U5$-infected cells.

A condition characteristic of most active plant cells, but particularly noticeable in cells in which the virus is about to appear, is the non-random distribution of organelles in the cytoplasm. The most obvious example is an apparently functional association between nucleus and plastids, in which specialized structures are involved. Chloroplasts become tightly adherent to the nucleus and remain so in spite of rapid streaming of cytoplasm around them. Approaching the nucleus before adhering to it, a chloroplast may put out a fine protrusion that attains a length of 5–30μ. The protrusion touches the nucleus and shortens as the plastid comes closer. A second protrusion from the opposite side of the same chloroplast occasionally appears, and becomes surrounded by spherosomes, mitochondria, etc. When the plastid itself becomes adherent to the nucleus the first protrusion may be still visible, extending over the surface of the nucleus; the second may have retracted. More than 30 chloroplasts have been seen adherent to a large nucleus.

The first sequence of virus emission seen and photographed was in an epidermal cell from the underside of a leaf inoculated 3 days earlier with $U5$. The microscope was focused on the nucleus of a cell, free from any indication of virus infection, between two obviously infected cells. A number of plastids adhered to the nucleus, and plastid projections were visible on its surface. The cytoplasm flowed actively over the nucleus. After half an hour, bubbles were seen around the nucleus, and bubbling continued actively for 5–10 min. Similar bubbling has been induced experimentally by physico-chemical agents (unpublished work) and seems to indicate a radical change in permeability of the nuclear membrane and nearby endoplasmic reticulum. Mitochondria and spherosomes were present and circulated in the adjacent cytoplasm. After the bubbling, plastids were no longer closely adherent to the nucleus, and gradually they became free to drift away in cytoplasmic streams. Cytoplasmic flow from the nucleus became concentrated mainly in one direction. The outflowing cytoplasm was denser than normal, and monolayer grey plates with a dark 2- or 3-layer spot in the centre began to appear (Fig. 1). A slower rate of flow from the other side of the nucleus allowed condensation of a few grey plates on the nuclear surface. The source of virus material seemed to be inside the nucleus, possibly around the nucleolus. In several cells when increase of visible virus ceased, the nucleolus was noticed to have lost its optical density or seemed smaller than it was before virus began to appear. Active flow of virus material from the nucleus continued for 10–15 min. (longer in other examples), and the grey plates circulated through the cell, giving it the typical appearance of a recent infection.

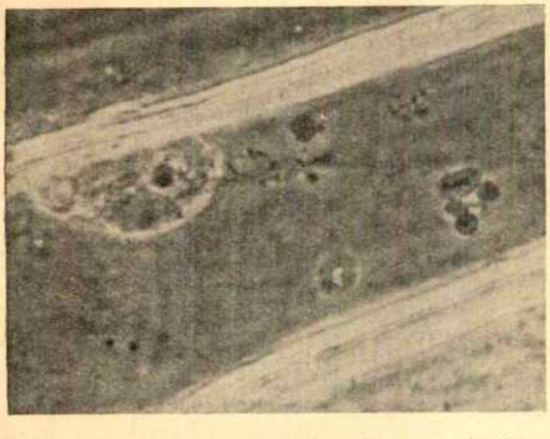

Fig. 1. Late stage in virus emission, virus aggregates (grey plates) formed and at a distance from the nucleus. Flow from the nucleus still apparent

The second full sequence seen and photographed was with strain $U1$ in a sub-epidermal cell from a young systemically infected leaf 4 days after inoculation. The preliminary bubbling around the nucleus was less active than in the $U5$ series, but in this and other examples of $U1$ infection there seemed to be a second site of activity in the cell. From around the nucleus with its adherent plastids, rapid and copious streaming occurred towards a vortex in the cytoplasm, some distance away. The basis of the vortex was a complex of cytoplasmic vesicles. Such vesicles have been interpreted as inclusions of vacuolar material within the cytoplasm[4]. In the vortex, spherosomes and mitochondria were in violent motion. Virus appeared as grey plates or as less-formal aggregates, mainly in the sluggish return flow from the vortex to the nucleus. The equivalent of a cytoplasmic vortex in the $U5$ infections seemed to be near or around the nucleus itself, rather than at a distance, as in $U1$.

In several $U1$-infected cells, seen after emission, amorphous material was present against the nucleus among the plastids. It drifted away with some of the plastids and circulated, apparently as the beginning of an x-body. It should be possible from further observation and biochemical tests to determine whether this material contains any virus protein or nucleic acid, or is debris from cell structures such as plastids.

The whole appearance of these events suggests a burst of virus emission quickly accomplished, rather than a mere assembly of virus on or at various distances from the nucleus. If the events have not been wrongly interpreted, they indicate that the final stages of tobacco mosaic virus multiplication begin within the nucleus. This agrees with Zech's findings[5]. The nucleolus seems to lose material during virus emission, and may be the source of virus nucleic acid. Possibly plastids are concerned with the synthesis of virus protein[6], and in the cytoplasmic vortex most of the nucleic acid and protein may be joined together. Finally, aggregation into grey plates, or other forms, often seems associated with vesicles or vacuolar membranes. Although such suggestions about the steps in virus formation are almost entirely speculative, it can be claimed with reason that whole virus is formed very soon after the burst of activity initiated in and around the nucleus of recently infected cells.

GENETICS

Frequencies of Hairy Pinnæ among Indian and Sinhalese Peoples

SINCE Tommasi[1,2] published a small pedigree, one of the phenotypes suspected to be holandrically inherited in human beings is that called hypertrichosis of the ears but more accurately hypertrichosis of the pinnæ of the ears. I have shown this to be completely *Y*-linked in my family, publishing a pedigree containing 181 people of 7 generations[3]. The age of onset is usually in late puberty, though in a few cases the hairs are not conspicuous until the men are about 25.

I have examined 495 men in India, and 414 men in Ceylon to count the frequency of this characteristic. These figures are given in Table 1. Andhra Pradesh is a south-eastern State of India with a population of about 33,000,000. In this State I counted the frequency of this characteristic among my co-travellers in buses and railway trains during 11 journeys travelling a distance of about 800 miles[3]. In the different parts of Ceylon where the counts were made many subjects stated that their ancestors had been local people for a long time.

Table 1

Place	Subjects	Total No.	No. with hairy pinnæ	Percentage with hairy pinnæ
India				
Andhra Pradesh	Co-travellers	345	21	6·1
West Bengal	Workers of Indian Statistical Institute	150	24	16·0
Ceylon				
General Hospital, Colombo	Outpatients	124	44	35·5
Coconut Research Institute, Lunuwila	Staff and labourers	109	35	32·1
Coconut Seed Multiplication Farm, Ratmalagara	Staff and labourers	60	26	43·3
Department of Agriculture, Peradeniya	Workshop men	58	23	39·7
Royal Botanic Gardens, Peradeniya	Garden staff	63	25	39·7

Statistical analysis shows that: (*a*) there is no significant heterogeneity between frequencies in different parts of Ceylon; (*b*) the frequencies of samples in Ceylon, Andhra Pradesh, and West Bengal differ significantly. Among the Sinhalese 295 were Buddhists most of whose ancestors had probably lived in Ceylon for 2,000 years; 97 were Christians, mostly Roman Catholics; 12 Muslims and 10 Hindus. Three of the Muslims and 3 of the Hindus had hairy pinnæ. There is no significant difference between the frequencies among Buddhists (37·8 per cent) and Christians (39·2 per cent).

I have also examined many women in the various localities but found none having hairy pinnæ, as is expected on the hypothesis of *Y*-linked inheritance. The fact that the frequency of hypertrichosis is higher in Bengal and Ceylon than in an intermediate region is compatible with the statement in the Mahawamsa, an ancient Sinhalese chronicle, that Ceylon was colonized from Bengal about 2,500 years ago.

The results presented here clearly show significant differences in the frequency of the hairy pinnæ between different populations. It would seem worth while making counts of the frequencies in various parts of the world. This requires very little effort and may prove to be as useful as the survey of blood groups and other biochemical characteristics in obtaining confirmatory evidence about the affinities and differences between different human populations.

I am grateful to all the subjects for their co-operation, and to the following people in Ceylon for helping in the survey: Drs. W. Pallie, V. Basnayake, M. L. M. Salgado, I. Samaraweera, J. Wanigasooriya and Mr. W. A. K. Fonseka.

Karyological Demonstration of Hybridization of Mammalian Cells *in vitro*

IN a recent publication, Barski, Sorieul and Cornefert[1] described the formation of cells with a hybrid karyotype in mixed cultures of two mouse cell strains *in vitro*. The experiments to be described show that this phenomenon is easily reproducible and that it is not limited to a pair of strains of strictly defined karyotypes.

The two cell lines used in our experiments are strains *NCTC* 2555 and *NCTC* 2472 of Sanford, Likely and Earle[2], ultimately derived from a single cell of mouse subcutaneous adipose tissue, as received from Dr. G. Barski by kind permission of Drs. Wilton R. Earle and Katherine K. Sanford. Both strains are populations composed predominantly of hypotetraploid cells but containing varying proportions of cells of higher ploidy[3]. The karyotypes of the hypotetraploid cells of the two strains, as established in the course of our experiments, are given in Table 1 and illustrated by Figs. 1,*A* and *C*.

Table 1

	NCTC 2555	*NCTC* 2472
Total number of chromosomes, modal	57	55
Total number of chromosomes, variation extremes	51–64	51–59
Number of biarmed chromosomes, modal	15	1
Number of biarmed chromosomes, variation extremes	11–16	1–3
Number of extra long telocentrics, modal	0	1
Number of extra long telocentrics, variation extremes	0	1–3
Minutes	?	0

It can be seen that the two cell types can be unmistakably identified by the presence of (*a*) a high number of bi-armed chromosomes, some of which represent good 'markers', in the cells of line *NCTC* 2555; (*b*) at least one extra long chromosome and a somewhat shorter one (not shown in Table 1, but visible in Fig. 1,*C*) with a sub-median secondary construction in the cells of line *NCTC* 2472.

Mixed cultures were initiated on January 3, 1961, by inoculating equal numbers of cells of the two lines into two media (a modified 199 (ref. 4) and *NCTC* 109 (ref. 5)) containing 10 per cent of heat-inactivated horse serum. Dispersion of cells for transfer was accomplished either mechanically or by trypsinization. The cultures were incubated at 37° C. in an atmosphere of 5 per cent carbon dioxide in air. Control cultures of the two strains separately were treated

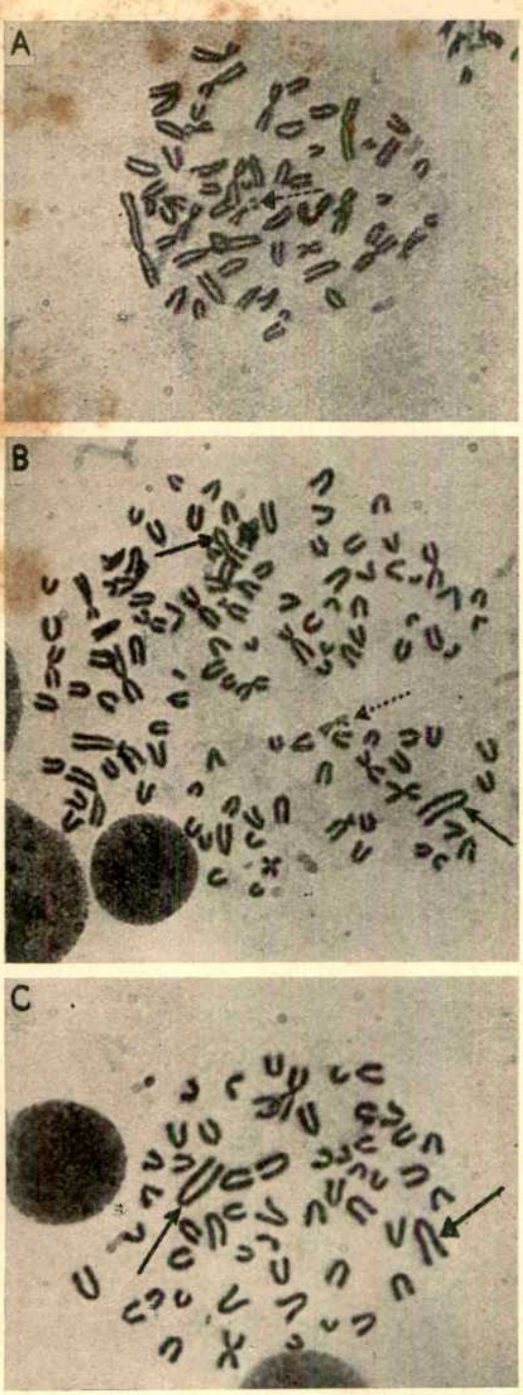

Fig. 1. *A*. Metaphase with 58 chromosomes (of which 15 are bi-armed) in a cell of strain *NCTC* 2555. Note characteristic metacentric (arrow) present in almost all cells of the strain. *B*. Representative example of hybrid cell with 112 or 113 chromosomes, of which 16 or 17 are bi-armed. Note the presence of the three 'markers' (arrows) shown in *A* and *B* *C*. Metaphase with 54 chromosomes (2 bi-armed) in a cell of strain *NCTC* 2472. Note the two 'marker' telocentrics: the extra long one and the somewhat shorter, submedially constricted one (arrows)

similarly. Karyological analyses of the mixed populations and of cells of each line grown separately were carried out at intervals on aceto-orcein squashes of colchicine-treated cultures.

At the time of writing (March 28), the occurrence of hybrid cells was observed in all four of the karyologically analysed mixed populations (two in medium 109 and two in medium 199). The hybrid cells are recognized by the total number of chromosomes and the number of bi-armed chromosomes expected from the fusion of hypotetraploid cells of the two strains, as well as by the presence of 'marker' chromosomes (Fig. 1,*B*). The frequencies of hybrid cells in the four mixed populations are at present approximately 1, 1, 5 and 10 per cent, the highest value having been observed in medium 109.

These results confirm the observations of Barski *et al.*, and furthermore show that the formation of hybrid cells is easily reproducible and is not restricted to two rigorously defined karyotypes: the latter is clear from the fact that strain *NCTC* 2472 used by us and strain *N* 1 *T* (derived from *NCTC* 2472) used by Barski *et al.* have somewhat different karyotypes. Thus the long constricted chromosome of line *NCTC* 2472 used by us has never been observed in Barski's line *N* 1 *T*; the cells of the latter strain very seldom contain bi-armed chromosomes, whereas those of line *NCTC* 2472 used by us all carry at least one such chromosome.

It may be pointed out also that, of the two strains involved in the mixed cultures of Barski *et al.*, at least one was re-isolated from a tumour induced by the inoculation of the original *in vitro* line. On the other hand, the cells used in our experiments never underwent animal passage since their explantation by Sanford *et al.* It is clear, therefore, that the tendency to cell fusion is not a result of animal passage.

These observations suggest that hybridization *in vitro* of other types of somatic cells should be equally possible. If this hope is justified, hybridization may become a useful tool for the investigation of a number of problems of somatic cell genetics, of oncology and of virology[6]. Examples of problems which are common to these fields and which hybridization *in vitro* could help resolving are: the genetic mechanism of variations in resistance to drugs and other chemotherapeutic agents observed frequently in tumour cells[7]; and the possible occurrence of zygotic induction[8] in virogenic cell lines.

The practicability of the method will depend to a large extent on the establishment of selective techniques for the detection of hybrid cells. Its applicability to the study of the mechanisms of cellular differentiation will require further the establishment of techniques for overcoming barriers of tissue specificity.

The technical assistance of Mlle. M. T. Thomas is gratefully acknowledged. This work was supported by a grant from the Rockefeller Foundation.

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. W. E. Ormerod: "The Study of Volutin Granules in Trypanosomes".

Friday, May 19

University of London (in the Physiology Theatre, Guy's Hospital Medical School, St. Thomas's Street, London, S.E.1), at 5 p.m.—Prof. W. M. Smart: "Some Aspects of Cosmology" (Fison Memorial Lecture).

Institution of Electronics (in the Large Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 7 p.m.—Mr. C. F. Whitbread: "Aerial Techniques".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Graduate Research Assistants (2) (with an honours degree in botany, biochemistry or chemistry) in the Department of Botany, to participate in research on the mechanism and biochemistry of photosynthesis—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 20).

Lecturer (with qualifications in biochemistry, and research and teaching experience) in the Department of Chemistry—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (May 22).

Lecturer in Pure Mathematics—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne 1 (May 24).

Staff Fellow in the Department of Physics, to contribute substantially to the research programme in low temperature physics being initiated in the Department, or to one of the existing programmes in nuclear physics and the physics of solids—The Assistant Registrar (Science), The University, Edgbaston, Birmingham 15 (May 24).

Lecturer or Assistant Lecturer in Bacteriology—The Registrar, The University, Leeds 2 (May 27).

Lecturer (preferably with a special interest in geomorphology) in Geography—The Registrar (Room 22, O.R.B.), The University, Reading (May 27).

Lecturer (with a good honours degree in metallurgy, and preferably some experience in research and industry) in Metallurgy—The Registrar, The University, Nottingham (May 27).

Research Assistant (graduate or prospective graduate, with a special interest in the field of growth hormones) in the Department of Botany, to undertake work on the physiology of ripening and senescence in annual plants—The Registrar, University College of Wales, Aberystwyth (May 27).

Assistant Lecturer in Botany—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (May 29).

Lecturer in Physics—The Registrar, The University, Hull (May 31).

Official Tutorial Fellow in Engineering—The Secretary, St. Catherine's College, 42 Banbury Road, Oxford (May 31).

Assistant Lecturer in Chemistry tenable in the Department of Physiology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (June 3).

Analyst (Dairy Chemist) (with a degree in science or agricultural science, or equivalent qualifications with emphasis on chemistry) in the Department of Agriculture, Hawkesbury Agricultural College, Richmond, New South Wales, Australia, for investigational work associated with dairy factory manufacturing problems—New South Wales Agent-General's Office, 56 Strand, London, W.C.2 (June 5).

Lecturer or Assistant Lecturer in Applied Mathematics; and a Lecturer or Assistant Lecturer in Pure or Applied Mathematics—The Registrar, The University, Hull (June 5).

Lecturers or Assistant Lecturers in Chemistry and Mathematics at the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 10).

Senior Lecturer or Lecturer (preferably with a knowledge of tropical soils) in Soil Science in the Department of Agriculture, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 10).

Lecturer in Psychology at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, June 15).

Lecturer or Assistant Lecturer (preferably with special qualifications and interests in protozoology, or in the ecology of terrestrial animals, or with special qualifications and interests in cytology and genetics) in Zoology at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 15).

Lecturer in Veterinary Physiology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 16).

Lecturer in Philosophy in the School of General Studies, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 17).

Senior Lecturer in Agricultural Engineering at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 20).

Chair of Physics (Electronic Computing) in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Senior Lecturer in Physics at the Royal Australian Air Force Academy (University of Melbourne)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

ASSISTANT LECTURER (Grade B) IN MATHEMATICS—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

CHEMICAL RESEARCH TECHNICIAN/ASSISTANT, to work on steroids with a team investigating endocrinology in relation to human biology and genetics—Dr. J. M. Tanner, Institute of Child Health (University of London), The Hospital for Sick Children, London, W.C.1.

ENTOMOLOGIST (with a university degree in science or agricultural science with specialization in entomology, some qualifications in plant pathology, and preferably experience in either agriculture or pest control) in the British Solomon Islands Protectorate, for entomological work in crop protection with special reference to control of anblypelta and brontispa causing damage to coconut palms; work will also cover insect pests of rice, stored copra, village food crops and cocoa, a new crop in the Protectorate—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/45/04.

RESEARCH ASSISTANT to help with current research on an immunological project concerned with rheumatoid arthritis—The Pathologist, Stoke Mandeville Hospital, Aylesbury, Bucks.

RESEARCH ASSISTANTS (2) (with a first- or second-class honours degree in geology) IN THE DEPARTMENT OF GEOLOGY—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

SENIOR TECHNICIAN (with experience in general laboratory work, photomicrography and histological techniques) IN THE DEPARTMENT OF ZOOLOGY—The Bursar, The University, Sheffield.

TAXATION OF SCIENTIFIC BODIES

IN the debate in the House of Lords on November 19, 1960, which arose out of the last report from the Advisory Council on Scientific Policy, Lord Adrian directed attention to the position of scientific societies as affected by the Rating and Valuation Bill now being considered by Parliament. The independent scientific societies in Britain, he pointed out, are a very important part of the organization for fostering progress in both pure and applied science. Their contribution to the encouragement of particular branches of science, as by the work of the Chemical Society or the Geological Society, has been immense, while others, like the Royal Society and the British Association, encourage science in general. They are a main forum for the exchange of ideas, and in retreating during the past decade from the idea of a Science Centre, so stoutly championed by Sir Robert Robinson, the Government has thrown on them a large share of the responsibility for providing scientific and technical libraries service for the country. Even to-day, Government action has scarcely begun to bridge the gap.

Nor is this all. Publication of periodicals as vehicles for original knowledge has become increasingly onerous, partly through the expanding scale of scientific work, and partly through mounting costs of printing, paper and postage. The Nuffield Foundation has already made some tentative inquiries into the possibility of alternative methods of publication and distribution; but, in the meantime, many of the scientific and other learned societies are strained to the utmost in carrying on the task of publication. Nor, as Lord Adrian also noted, should it be forgotten that such societies have also become the representative bodies that can be called on by the State for advice, and membership of which gives status to the individual. In this connexion alone, their value in bringing scientists together is important, and they have even greater direct value in providing incentives and guidance to young men.

Prof. C. F. A. Pantin has directed attention in a letter in *The Times* to another aspect. He emphasizes the extent to which the Government draws on the services of scientific men and women on advisory boards and committees of various kinds in guiding the scientific effort of the nation. For this great service they rarely receive reward of any kind, and their ability to serve efficiently depends directly on the existence of the learned societies which they maintain by their voluntary subscriptions. Their efficiency depends not merely on the maintenance of publication but even more on that personal discourse by which we all keep in touch with rapid advance of knowledge, and which Lord Adrian himself emphasized.

Lord Adrian pointed out that for more than a century the scientific societies of Britain have been assisted by the State in the provision of buildings for some of them, by exemption from rates, and recently by grants for publications. It was a thoroughly British arrangement. The societies have kept their freedom and independence, and the help they receive from the State enables them to shoulder the much greater responsibility that both the rapid advance of science and the national interest demand. There has been no serious complaint about the way the arrangement has been working recently, or about the goodwill of the Government towards scientific societies. It is the danger which threatens their finances through the Rating and Valuation Bill with which Lord Adrian was concerned.

The effect of the proposals of the Bill, in accordance with a recommendation of the Pritchard Committee, would be that societies which are now exempt would in future be required to pay half the full rateable value of their premises. To shoulder these new burdens without any increased help, the scientific societies will be obliged to raise their subscriptions and cut down their expenses; for example, by reducing the size of their periodicals and curtailing the number of meetings they arrange. There may well be room for more careful scrutiny and some reduction in the number of papers published; but it is one matter for that to take place on the initiative of a scientific society itself, and quite another when it is forced on the society by financial stringency alone. No doubt the major national societies will survive the crisis, even if some of them are maimed; but, as Lord Adrian observed, some of the smaller bodies dealing with highly specialized branches of science may be faced with extinction if the recommendations of the Pritchard Report are adopted and there is no countervailing assistance from the State.

When Lord Adrian made this powerful plea for due consideration before action is taken to reduce so seriously the great scientific asset Great Britain has in the independent scientific societies, Lord Hailsham, the Minister for Science, responded by asking if Lord Adrian could induce the societies to inform either him or the Chancellor of the Exchequer on the exact position, which is already under consideration by the Government. Lord Hailsham agreed as to the force of Lord Adrian's remarks, but the Minister of Housing and Local Government, Mr. H. Brooke, made no specific reference to this aspect when moving the second reading of the Bill in the House of Commons on November 30. He merely explained that the Government had decided to follow the Pritchard Committee's recommendation and repeal the total exemption from rates given by the Scientific Societies Act of 1843 to scientific and other societies, the definition having proved too difficult to apply in practice. Instead, under the Bill, practically every organization now obtaining benefit under the 1843 Act would in future qualify automatically for 50 per cent de-rating, and the local authority would have discretion to give up to complete exemption if it thought fit.

Although it was not mentioned in the debate, a small deputation from the Parliamentary and Scientific Committee had already discussed the matter with the Minister on July 27. Then, after the presentation of the Bill to Parliament, at a meeting of the Rating Sub-Committee, it was agreed to take steps to secure certain amendments during the passage of the Bill through Parliament. First, it was proposed to make it clear that the hereditaments to be given mandatory 50 per cent rating relief under clause 8 (1) will include all hereditaments properly established for scientific purposes as well as charitable purposes. Secondly, it is proposed that the power given to rating authorities in subsection (4) of this clause 8 to reduce or remit the payment of rates chargeable in respect of hereditaments, and including hereditaments not established for profit and concerned with science, should be transferred to the Minister of Housing and Local Government, so that there should be central decision.

On the first amendment, it might be observed that scientists may well feel that there is a certain lack of dignity if relief in this matter is made to depend on charity and not on the nature of the scientific society itself. There may be difficulties, as Lord Hailsham suggested; but the need is a national one and deserves a certain dignity of treatment whether from the point of view of the scientist or of the nation. On the second, because the matter is a national one, it is neither just nor appropriate to place on local authorities the financial obligation to meet charges which properly belong to the whole nation, quite apart from the matter of uniformity in policy which central decision should secure.

When this clause was considered in Standing Committee in the House of Commons on February 14*, the position of the scientific and learned societies was pressed by Mr. D. Wade and Mr. J. T. Price; but the Minister maintained that national importance by itself ought not to be taken as entitling a body to relief from rates. This, of course, specifically rejects the argument advanced by Lord Adrian as well as by Prof. Pantin in spite of the fact that Mr. Brooke himself agreed that it would be a grave loss to the nation if some of the societies in question ceased to exist. There was in fact some general support for the view that since the societies in question are mostly bodies of national character, there is no cogent reason why any special financial assistance they received should come from the local rate-payers. Mr. Mitchison had urged on February 9 that the Government should accept the full re-rating of these societies, and that the consequent burden should be met in full by the Government as a Government concerned with science and the high reputation of the country in these matters.

Because of the form and content of the Bill and the ordinary rules of procedure, amendments requiring the Government to give full rating relief could only be proposed by the Government itself. This undoubtedly appears to be the most dignified procedure; but, while declining to give a pledge that whatever body had received exemption from rates hitherto should now be entitled to turn to the Exchequer for re-imbursement of any rates it might have to pay, Mr. Brooke nevertheless stated that the Treasury would be ready and willing to look at the publication grants which it makes, in particular to the Royal Society, and to consider the position which has arisen. The problem, he said, cannot be solved by legislation; he had been in touch with both the Minister for Science and with the Chancellor of the Exchequer and had their assurance that at the time when the effects on the learned societies could be assessed in the light of the new revaluation they would be fully prepared to meet representatives of the societies for a full examination of those effects on the finances of the societies.

Mr. Brooke maintained that the question is what their financial position will be when the Bill becomes an Act and when the new valuations have been made, and that there will be ample time for these conversations. The societies would not begin to pay rates until April 1964, and then on 10 per cent of their rateable value; but we should know some time in 1962 what the actual liabilities for rates of the societies will be. For this reason, he recommended the Committee not to accept the amendments, but that the Government should be held to the assurance he had given.

During the third reading of the Bill on May 10, Mr. Brooke stated that a deputation from the Royal Society and the British Academy, acting on behalf of the national learned societies, had met the Minister for Science and the Financial Secretary of the Treasury, and that it was generally considered that the needs of such societies should be dealt with outside the framework of the Bill. A joint review of the needs of learned societies of national importance is to be undertaken after the Bill becomes law.

There are thus hopes of a satisfactory settlement which meets the needs of the societies and of the nation on terms conducive to mutual dignity and respect. None the less, there is no justification for any relaxation by scientists over the next few years; they must continue to emphasize the place and function of the scientific society, and its value not simply to the advancement of science but also in the service of the Government and nation.

A SURVEY OF ORIENTAL GRASSES

The Grasses of Burma, Ceylon, India and Pakistan (excluding Bambuseae)

By Dr. N. L. Bor. (International Series of Monographs on Pure and Applied Biology. Division: Botany, Vol. 1.) Pp. xviii+767. (London and New York: Pergamon Press, 1960.) 160s. net.

NOTHING gives greater pleasure than to welcome a comprehensive work based on dedicated study by a recognized authority. The author of this book began his work on the Gramineae more than thirty years ago, and it deals with the species, both wild and introduced, of 243 genera of this important family which occur in the sub-continent of India. Presented mainly as a practical handbook, it surpasses the author's modest claims.

The general part of the text gives an excellent account of the morphology of the grass plant (pp. 1–22), deals with dispersal methods, uses of grasses and enumerates certain obnoxious ones. Unfortunately, not all these unusual observations are indexed. The systematic part of the text (pp. 61–681) presents the genera and species grouped in three tribes of Panicoideae and thirty-six of Pooideae. Critics of the alphabetical sequence should read carefully the reasons given on p. 77, and bear in mind the problems implied, as well as exemplified, in the concise, but cogent, section on taxonomy and phylogeny (pp. 61–76). Taxonomists will wish to know the precise date of publication; this was December 14, 1960. The eighty line-blocks, though uneven in style and quality, are of particular interest in showing a comparison of the work of the ten artists. (Not mentioned in the book, they are: Mr. G. Atkinson, Dr. Bor (Figs. 3, 4 and 70), Miss L. Ripley, Miss S. Ross-Craig, Mr. J. Shaw, Miss M. Smith (Figs. 31 and 77), Miss E. M. Stones, Mrs. O. Tate, Mr. P. Taylor and Mr. W. E. Trevithick). The bibliography is good, including almost 600 items; the 89 works by Dr. Bor testify to his preparatory industry. The index lists about 4,800 entities, but omits all varieties. The author acknowledges his indebtedness to J. D. Snowden in the genus *Sorghum*, and Dr. A. Melderis has given assistance in the *Triticeae*.

The magnitude of Dr. Bor's achievement can be gauged from the number of taxonomic entities involved: the 243 genera include 1,250 (± 5) species, but the index shows that he has also placed some 3,500 specific synonyms. Ninety-seven of the genera are monotypic in the area; 60 per cent have less than three species (high proportions, even for Gramineae, perhaps because of introductions); thirty-two have more than ten. The author gives full synonymy for the genera, he has checked all references, examined almost all the type specimens (but does not indicate which) and gives caryological data. The taxonomy is commendably explicit, with full notes covering difficult cases; but one regrets the author's caution, as so few will reach a better position than he to decide some of the issues he leaves "to later research". Need he have deliberately placed the same nine species in both *Erianthus* and *Saccharum*? As to the nomenclature, the author's deep concern with the plants themselves seems to have made him impatient of some of the niceties of the International Code. The inclusion of the same new variety in both *Andropogon polyptychus* and *Dichanthium polyptychus* makes it invalid (*vide* Article 33), like the new combination similarly duplicated on pp. 151 and 212. The text is unmarred by typographical errors, but users may add *Ischnochloa*, *Sorghastrum* and *Themeda* to the list of Andropogoneae on p. 80.

Dr. Bor has completed a study of noble proportions which will become relied on for Asiatic grasses as is Hitchcock's invaluable manual for the North American; the keys make it more useful, the lack of descriptions being less of a handicap for grasses where keys so often use technical characters. Significant scientifically and superlatively well written, the book shows a beautiful balance of original and derived information; at every opening one observes the author's practical knowledge of the grasses of India and his familiarity with the academic sources. This fitting addition to the literature is especially welcome at the present stage in the development of agriculture in Asia. What a pity the high price will tend to restrict ownership of the book to institutions.

JOHN LEWIS

VIRUSES IN DISEASES OF CHILDREN

Viral Infections of Infancy and Childhood

A Symposium of the Section on Microbiology, The New York Academy of Medicine. Edited by Prof. Harry M. Rose. Pp. xi+244. (New York: Hoeber-Harper, 1960.) 8 dollars.

THIS beautifully produced symposium provides a concise account of recently acquired knowledge and current concepts in its chosen field. The approach is epidemiological, with the accent on laboratory aspects.

The first two chapters summarize recent work on the infectivity of ribonucleic acids extracted from poliovirus (H. E. Alexander) and from virus-infected cells (J. S. Colter)—excellent accounts, though of questionable relevance to many readers of this book. About half the 232 pages of text are devoted to enteroviruses, opening with chapters on coxsackie infections (H. L. Hodes) and virus myocarditis (S. van Creveld). The latter chapter gives a particularly useful review and an account of the outbreak of Coxsackie myocarditis of the newborn in Amsterdam in 1955. This dangerous disease is a threat to infants in the nurseries of maternity units, and van Creveld suggests the possibility of active immunization of pregnant women or gamma-globulin prophylaxis for infants born during epidemics of 'summer grippe'. The general properties of *ECHO* viruses are described by J. L. Melnick, and A. B. Sabin presents a particularly well-arranged review of the role of *ECHO* viruses in human disease. Fever, meningitis, and sometimes skin rash have been prominent features of various outbreaks, but associations with such other symptoms as diarrhœa and respiratory illness also appear to be significant. D. A. J. Tyrrell and his colleagues describe their investigations on the outbreak of meningitis and skin rash in England in 1956, caused by type 9 *ECHO* virus, which resembles a Coxsackie group *A* virus in its virulence for suckling mice. Long-term observations of enterovirus infections among children in a Washington orphanage are summarized by L. Rosen and associates. Dalldorf discusses the increasingly recognized role of enteroviruses other than poliovirus in paralytic disease.

Respiratory infections are introduced with a challenging and controversial exposition of the principles of influenza vaccination by F. M. Davenport and A. V. Hennessy, a subject discussed further by E. C. Curnen. There follows an account by A. Isaacs of interferon, which offers an alternative method of approach to control of virus infections. R. M. Chanock and his associates give a useful review of newly discovered respiratory agents, sounding a proper note of caution in relation to interpretation of associations of these viruses with disease. Adenoviruses are surveyed briefly by W. P. Rowe, who also gives an excellent account of salivary gland virus and related infections of animals. Recent advances in varicella and measles are reviewed by S. L. Katz and his colleagues.

This book will be of particular interest to medical virologists, clinical pathologists and clinicians who are concerned with infectious diseases and children.

N. R. GRIST

FACTS ABOUT INDUSTRIAL GROWTH

Patterns of Industrial Growth, 1938–58

(Statistical Office of the United Nations, Department of Economics and Social Affairs.) Pp. viii+472. (New York: United Nations; London: H.M. Stationery Office, 1960.) 8.50 dollars; 60*s.* 6*d.*

THE statistical staff of the United Nations has made a heroic attempt to present a picture of industrial growth during twenty years in the 'free' world. In many of the tables the countries are grouped by continent or sub-continent; still more valuable is a four-fold classification by degree of industrialization. Data are given for 1938, 1948, 1953 and 1958 or for the periods lying between each. There are also separate data presented for each country.

The volume should be of the utmost use for students of economic growth, but it should also be serviceable to those of more general interests, whether political or technological. Many a generalization can now be checked by reference to the facts; it is likely that many misconceptions will be removed.

Some of the most prominent tables show growth expressed as average annual percentage rates of increase in each of the three periods. This gives the right orientation, since the most interesting problems of modern economics are concerned with the inter-relations between growth-rates. The most central figure in the volume is that giving the average world figure for the annual rate of growth in mining and manufacturing together, namely 4·4 per cent per annum. The increase in output for each person employed in them was 2·0 per cent per annum or 2·7 per cent per annum—depending on the method of measurement.

The lowest class of countries, by degree of industrialization, showed an increase in production of 4·6 per cent per annum, and, it is satisfactory to note, an increase in output per person of 1·7 or 2·1 per cent. But the growth was from a very low level. The value added per person employed in manufacturing in the lowest class group in 1953 was less than a quarter of the value added for each person so employed in Europe, and little more than a twelfth of that per person employed in the United States and Canada (together).

There is a striking table (p. 17) showing a close correlation between the rate of increase of production and the rate of increase of production for each person engaged. No support at all (pp. 26–9) can be found for the view that strong growth tends *per se* to be inflationary; there is no correlation between the rate of industrial growth and the degree of inflation as between countries.

Much selection was needed even for this massive volume. It could be argued that too much space is given to tables of percentage distribution between groups. The explanatory text is workmanlike and raises many interesting points, but in regard to causes we can still only be at the beginning of judgment.

ROY HARROD

PLANT PATHOLOGY

Plant Disease Handbook

By Dr. Cynthia Westcott. Second Edition. Pp. xii+825. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1960.) 101*s.* 6*d.*

THIS is an enlarged edition of the book by the same author written some ten years ago, and except for slight alterations the layout remains the same. This edition, however, deals with a much wider range of host plants, and there is a noticeable expansion in most sections as a result of discoveries in research during the past decade. The book in fact lists more than 2,000 diseases occurring on more than 1,000 host plants.

It is a large book of five chapters preceded by an author's note on "How to use this Book". The first three chapters are very short—Chapter 1 is the usual introduction to the subject describing the nature of plant diseases and the principles underlying their prevention or control. Chapter 2 gives an up-to-date account of the chemicals used in control practices, and Chapter 3 is a list of the various plant pathogens, with special attention paid to the fungi, in the form of a short classification.

The next two chapters occupy nearly 700 pages between them and provide what we can call the substance of the book. Chapter 4 includes no less than 40 different types of disease placed in sections which have been created in somewhat arbitrary fashion according to symptoms shown by the hosts (for example, cankers, galls, leaf spots, mildews, rusts, wilts and so on). These sections are in alphabetical order, and in each, the various pathogens which can cause that type of disease appear in alphabetical order accompanied by details of suitable control measures, and the life-history and structure of the parasite. Chapter 5 is a list of host plants in alphabetical order according to the common name or the Latin name where the author considers this is more helpful in avoiding confusion. Below each host name is a full list of its diseases with short comments about the more important ones. At the end there are a glossary, a selected bibliography and a good index. For the purpose of emphasizing special diseases or important parasites there are about 100 illustrations in the form of photographs or line drawings. The paper and print are of the high quality which we always associate with American publications of this kind.

The book is, in the main, a list of plant diseases, but I think it is more than that. It covers an extensive field, and is a condensation of experience gained by the author over 30 years while travelling about the American continent to give advice on plant disease problems. There is certainly no comparable book in this field in Great Britain. Its scope is vast and its contents are intended for American nurserymen, growers and advisers, but even allowing for plants peculiar to the American continent I consider there is much in its pages which can be of value to horticulturists and plant pathologists in Britain. The diseases of ornamental plants are well catered for, and this branch of pathology is one in which British pathologists are not well versed.

The book claims that without special training, seedsmen and growers will be able to use it as a working guide and reference book in diagnosing and treating plant diseases. I doubt whether such people will appreciate the rather formidable lists of scientific names, and whether laymen in general can achieve accurate diagnoses despite the apparent simplicity of the system here propounded. Nevertheless, I consider that the book can provide valuable assistance to professional horticulturists, advisors and plant pathologists generally. Much of the information has had to be condensed, but it is still an impressive collection of facts skillfully cross-referenced so that most people will find little difficulty in finding quickly the knowledge they seek. It is my opinion that Prof. Whetzel, to whom the book is dedicated and whom I remember with affection, would have been pleased with this contribution by his former pupil.

D. E. Green

CONSTANTS FOR BINARY SYSTEMS

The Physico-chemical Constants of Binary Systems in Concentrated Solutions

By Prof. Jean Timmermans. Vol. 4: Systems with Inorganic + Organic or Inorganic Compounds (Excepting Metallic Derivatives). Pp. xi+1332. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1960.) 293*s*.

THIS volume is the last of a series of four prepared by offset printing and contains 900 pages of data on binary mixtures in which at least one of the components is an inorganic compound. The general arrangement follows that adopted in the earlier books and the same properties are recorded. Volume 4 presents the long-awaited indexes of which there are three, one for organic compounds, one for inorganic compounds and one for authors' names. Binary mixtures are not indexed, but under a molecular formula appears the name of one of the components followed by an unclassified list of all pages where the properties of mixtures containing that compound appear. This is a very unsatisfactory arrangement. Suppose, for example, that it was required to find the densities of acetic acid-benzene mixtures, then 166 pages under the title acetic acid would have to be searched. The author index is simply an alphabetical bibliography, so while it is possible to take a page of the main text and find the source of the work cited, it is not possible to look up an author's name and find where his work is included in these volumes.

A pair of names of compounds printed boldly at the head of each page affords assistance in searching the book, but it is a pity that somebody conversant with the peculiarities of the English language was not consulted regarding these titles so that names such as sulphur anhydride and carbon oxide could have been avoided. Some errors were noted in this volume, which contains four pages of errata applicable to Volumes 1–3. However, most of the errors previously pointed out by myself and other reviewers have not been listed. The book ends rather quaintly with a short list of papers which the author has not been able to find.

In spite of the imperfections of the indexing of these volumes this work will be invaluable to many workers as a first reference.

E. F. G. Herington

PHYSICAL TECHNIQUES IN METALLURGY

The Physical Examination of Metals

Edited by Prof. Bruce Chalmers and Prof. A. G. Quarrell. Second edition. Pp. vii+917. (London: Edward Arnold (Publishers), Ltd., 1960.) 168*s*. net.

IN the present edition of this book one large volume replaces the two volumes of the first edition. Further, the original authors have become editors for a team of contributors who provide coverage of what is relatively broad subject-matter. This change, of course, represents a current trend, and although the method has disadvantages, it is well suited to the subject in question. The book is thus a completely new one.

It deals with numerous methods of examination, ranging from those providing information on the atomic scale to those concerned with the detection of flaws. Somewhere in between come techniques for the measurement of basic electrical, thermal, and magnetic properties. Apart from the more obvious topics, the book includes details of many not necessarily expected, such as the damping capacity of metals, measurements of elasticity using mechanical waves, the use of radioactive isotopes, and vacuum techniques. A relevant method not included is that of radiography, but presumably the editors think that this is more than adequately covered in other books. However, in this connexion it should be pointed out that other X-ray techniques, such as X-ray diffraction and microradiography, as well as autoradiography are described.

For each subject the underlying physical principles are well described in clear and satisfactory physical language. The actual experimental methods are discussed, and the treatment is illustrated by typical results. No doubt there are omissions, particularly in detail, and the approach in some sections may place most emphasis on the physics of the subject. However, even if this is true, the book unquestionably achieves its aim, that is to bring together for metallurgists the principles of a wide range of physical techniques.

The volume is attractively produced, well printed and illustrated, and the text is clearly presented. All concerned with its production should derive satisfaction from the final result.

A. R. Bailey

Annual Review of Microbiology

Vol. 14. Edited by Charles E. Clifton, in association with Sidney Raffel and Mortimer P. Starr. Pp. vii+391. (Palo Alto, California: Annual Reviews, Inc., 1960.) 7 dollars.

OVER a period of thirteen years, microbiologists have become confident of finding in the *Annual Review of Microbiology* concise and critical surveys of literature covering a wide range of topics. Volume 14 comes up to the standard set by its predecessors.

This year, out of a total of seventeen articles, four will be of direct interest to virologists. Recent observations relating to the fine structure of virus-infected cells have been ably reviewed by Rose and Morgan, although it is, perhaps, to be regretted that this article is not illustrated. D. L. Walker, discussing *in vitro* cell-virus relationships resulting in death of the cell, provides a valuable survey of the links between cell degeneration and virus-induced metabolic alterations. Intramural spread of bacteria and viruses in human populations is discussed by Williams, and Kissling reviews ecological aspects of arthropod-borne viruses of man and other animals.

Scherbaum's contribution provides an overdue comparison of observations on synchronously dividing micro-organisms with established knowledge of normal cellular metabolism. In discussing the problem of protein synthesis, Novelli has focused his attention on the sequence of enzymic steps between free amino-acids and the formation of peptide bonds, as observed in cell-free systems.

Other topics reviewed include: microbial nutrition; nutrition, metabolism and pathogenicity of mycoplasmas; variation in phytopathogenic fungi; genetics and cytology of *Chlamydomonas*; gene action, a review of the gene-to-protein relationship; immunological speculations; interpretation of immuno-diffusion tests; energy metabolism of chemolithotrophic bacteria; industrial fermentations; intracellular symbiosis in insects and enzyme localization in bacteria.

This volume also includes a cumulative index of authors and chapter titles for Volumes 1–14, an addition which will be of inestimable value to all faced with the task of reviewing the literature.

B. A. Newton

Non-Benzenoid Aromatic Compounds

Edited by David Ginsburg. Pp. xii+543. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 135*s*.

THE editor was clearly faced with a dilemma in devising a terse yet fully descriptive title for this collection of review articles. As Sir Robert Robinson points out in the foreword, the word 'aromatic' in its ordinary sense was applied to benzene and its derivatives; later it began to imply a measure of stability associated with a benzenoid structure. This brings in the pyridine group, and there is a remarkable similarity in the physical properties of analogous compounds in the thiophen and the benzene series. At the other end of the scale, it was stated at the Chemical Society Symposia, Bristol, 1958 (Special Publication No. 12) and reiterated herein that cyclo-octatetraene shows no aromatic character and behaves as a typical polyolefin.

Appropriately, therefore, the first chapter discusses 'aromaticity' from the theoretical side for both benzenoid and non-benzenoid compounds, with particular reference to the π-electron concept. The chapter on the cyclobutadiene group, which includes diphenylene, is a considerably extended version of matter presented at Bristol. The chemistry of ferrocene and related compounds forms the major part of the section on cyclopentadiene derivatives: pentalene and heptalene follow. Azulenes were considered at Bristol, but are here discussed in great detail in two chapters dealing respectively with the theoretical and preparative aspects; the latter includes most of the recent work of Hafner. The seven-membered systems, tropones and tropolones, form another major topic, a condensed form of more than five hundred papers; this group includes colchicine. The final two chapters discuss shortly cyclo-octatetraene and higher cyclopolyolefins.

To the main texts of most chapters, notes of later publications have been added at the proof stage, their number indicating the lively interest being taken in these subjects. We thus have a timely, authoritative, well-documented and up-to-date series of monographs on an interesting group of substances.

B. A. Ellis

Investigations on Norwegian Cirque Glaciers

Edited by W. V. Lewis. (Royal Geographical Society Research Series, No. 4.) Pp. iv+104+19 plates. (London: Royal Geographical Society and John Murray (Publishers), Ltd., 1960.) 22*s*. 6*d*.

THIS volume gathers together many valuable observations which are mainly concerned with two small cirque glaciers in the Jotunheim, Norway. These particular glaciers have been studied in great detail by a number of specialists, each of whom reports his or her own observations in the book. The geology of the area, as it affects glacial action, is usefully discussed by Dr. M. H. Battey, while Mrs. J. M. Grove supplies very detailed observations of the ice banding of both glaciers, from which she deduces their régime and movement. A detailed physical analysis of the ice-fabric of Vesl-Skautbreen is contributed by Dr. R. J. Adie, and survey results are briefly discussed by J. E. Jackson and Miss E. Thomas.

The major contribution is the valuable analysis by Dr. J. G. McCall of observations made in two tunnels cut through to the corrie back-wall. These results, which required extremely accurate survey work, have given a detailed picture of the mechanics of flow of a small and fairly simple type of corrie glacier. They show that although rotation is important it is not the only type of movement. The observations made of the ice–rock contact at the base of the glacier are incorporated in a discussion of the processes of corrie formation. W. R. B. Battle's contribution discusses techniques and results of recording changes in temperature in bergschrunds, mainly at the Jungfraujoch, Switzerland, and in Norway, with the view of obtaining quantitative evidence of the part played by thaw-freeze in corrie formation. The first and last chapters are contributed by the editor, W. V. Lewis, in which he introduces the authors and sums up the results by applying them to the formation of a typical Lake District corrie, Blea Water.

Although much of the work reported here was done nearly a decade ago and some results have already been published, this very well-produced and illustrated volume is a worth-while contribution to glaciological literature. C. A. M. King

THE AMINO-ACID SEQUENCE OF SPERM WHALE MYOGLOBIN

Chemical Studies

By A. B. EDMUNDSON

The Rockefeller Institute, New York 21, N.Y., and Medical Research Council Unit for Molecular Biology,
Cavendish Laboratory, Cambridge

AND

C. H. W. HIRS

Department of Biology, Brookhaven National Laboratory,
Upton, Long Island, N.Y.

APPLICATION of the method of isomorphous replacement has enabled Kendrew and his colleagues to determine the structural configuration of sperm whale myoglobin first to a resolution of 6 Å. (ref. 1) and more recently to a resolution of 2 Å. (ref. 2) by X-ray analysis of type-*A* crystals of the protein. At the suggestion of Dr. Kendrew, a detailed chemical study of the primary structure of the protein was initiated several years ago, and is being continued by one of us (A. B. E.) at Cambridge. Some of the results obtained thus far in the chemical approach are summarized in the present article. Recently, Kendrew *et al.* (see accompanying article) succeeded in deriving an almost complete amino-acid sequence from the electron density distribution at 2 Å., and the correlation of their proposed sequence with the chemical results is presented in their article.

Our investigation has been concerned with three problems: (1) the derivation of an empirical formula for sperm whale myoglobin; (2) the fission of the single peptide chain in the protein by tryptic hydrolysis as a preliminary step in the elucidation of the amino-acid sequence; and (3) the identification of the tryptic peptides derived from the ends of the peptide chain by end-group methods and sequence determinations.

Amino-acid Composition of Sperm Whale Myoglobin

Since the earlier work of Bodo and Kendrew (personal communication) had demonstrated that crystalline sperm whale myoglobin could be resolved chromatographically into several components, an inquiry into the nature of the structural variations responsible for the inhomogeneity became of considerable importance in connexion with more refined X-ray studies, as well as with the projected, detailed chemical work.

Crystalline sperm whale myoglobin (samples kindly provided by Dr. J. C. Kendrew) was fractionated by the method of Bodo (personal communication; cf. Boardman and Partridge[3]). The protein was chromatographed as the carboxy derivative (COMb) at 4° on the sodium form of 'Amberlite *IRC*–50' at *p*H 5·86 and *p*H 5·88, with citrate buffer, 0·34 *N* in sodium ion concentration, saturated with carbon monoxide, as eluent. Resolution of the protein into five hæm-containing components, and approximately 2 per cent of colourless proteins was achieved. Its chromatographic behaviour in the *p*H range 5·82–5·92 was studied with the view of the definition of optimal conditions for the preparation of each of the components in a purified form.

Fractions containing components I, II, III, IV + V, and V as the predominant (> 90 per cent) constituents were isolated. Components I, II and III accounted for 2–3, 7–10 and 20 per cent, respectively, of the hæm-containing protein in crystalline sperm whale myoglobin; components IV and V together accounted for the remainder.

After acid hydrolysis, each of the fractions was subjected to quantitative amino-acid analysis by the procedure of Spackman *et al.*[4]. The results are summarized in Table 1, and clearly show that, within the experimental errors, the amino-acid composition of the hydrolysate of fraction I, which is known to be contaminated by colourless protein(s), exhibits a significantly different composition. The constancy of the amino-acid composition of the acid hydrolysates of fractions II–V indicates that components II–V, and probably component I as well, are separate species of myoglobin molecules, which we propose to designate as myoglobins II–V.

Table 1. SUMMARY OF THE AMINO-ACID ANALYSES OF CHROMATOGRAPHIC COMPONENTS OF MYOGLOBIN

The composition of each component is presented in terms of the molar ratios of the constituent amino-acids

Amino-acid	Molar ratios of amino-acid residues Component I	Component II	Component III	Components IV + V	Component V
Aspartic acid	9·08	8·18	8·07	8·04	7·95
Glutamic acid	17·6	18·8	19·4	18·7	18·8
Glycine	11·0	11·2	11·0	11·1	11·0
Alanine	14·9	16·7	17·1	17·2	16·6
Valine	7·71	7·96	7·83	8·36	8·01
Leucine	15·8	17·9	17·9	18·1	18·2
*Iso*leucine	7·89	9·22	8·98	8·94	9·09
Serine	6·78	6·13	6·27	5·90	5·74
Threonine	5·45	4·87	5·15	5·18	5·03
Methionine	1·87	1·95	1·90	1·97	1·98
Proline	5·19	4·06	4·19	3·90	4·03
Phenylalanine	5·85	6·15	5·98	5·96	6·12
Tyrosine	3·70	2·94	2·94	2·79	2·92
Histidine	10·1	11·9	11·6	11·6	11·8
Lysine	16·7	19·2	18·8	18·9	19·1
Arginine	4·15	4·15	3·93	4·01	4·05
Tryptophan				1·86	
Amide ammonia.				(7·2)	(7·4)
Integral No. of residues	145*	151*	151*	153	151*

* The totals do not include values for tryptophan. Since the crystalline myoglobin from which these components were separated had a tryptophan content equivalent to 1·58 residues per mole, it is probable that all the components contain two residues of tryptophan.

Rumen[5,6] has recently resolved the structurally similar myoglobin of seals (cf. Scouloudi[7]) into several components by chromatography on *CM*-cellulose. The seal myoglobin components differed electrophoretically (cf. finback whale myoglobin[8]), and it is, therefore, possible that variations in amide content are responsible for the chromatographic inhomogeneity.

Since myoglobin IV and myoglobin V represent the major constituents of crystalline sperm whale myoglobin, the fraction containing these two proteins was selected for structural study. To complete the amino-acid analysis, fraction IV + V from sperm whale myoglobin was subjected to alkaline hydrolysis by the procedure of Drèze[9], and the tryptophan content of the hydrolysate was determined by the starch column method of Moore and Stein[10]. The tryptophan value obtained is given in Table 1, and indicates that myoglobins IV and V both contain two residues of tryptophan per molecule. The amino-acid composition of myoglobins IV and V thus involves 153 residues and approximately 7 amide groups. The molecular weight based on this composition (including the hæm group and the terminal molecule of water) is 17,816.

The chromatographic differences between myoglobins IV and V and the other components remain without explanation. The possibility that the components differ in amide content is at present under investigation.

Peptides obtained on Tryptic Hydrolysis of Myoglobins IV and V

The absence of cystine (cf. Table 1) permitted the direct use of the heat-denatured protein as a starting material for work on the peptides. After the protein was subjected to tryptic hydrolysis at *p*H 8 or at *p*H 9 for 16–20 hr. at 40°, the hydrolysate was separated into a soluble fraction, and an insoluble fraction with which all the hæm was associated. From the soluble fraction 20 peptides and free lysine were isolated in yields of 7–82 per cent by chromatography on 'Amberlite *IRC*–50' and 'Dowex 50–*X*2'. The results obtained on amino-acid analysis of these peptides are summarized in Table 2.

The generally high purity of the peptides revealed by the analyses in Table 2 is noteworthy, and the composition of each peptide is clearly defined by the molar ratios of its constituent amino-acids. The compositions are consistent with the specificity of trypsin, since each peptide, with the exception of the carboxyl terminal peptide, Tryp-16 (which will be considered later), contains at least one residue of lysine or arginine. Peptides Tryp-11, -12 and -19 differ from peptides Tryp-9, -14 and -15 only by the presence of an additional lysine residue. It has therefore been tentatively assumed that free lysine (Tryp-7) was released from each of the three regions of the peptide chain represented by these peptides, although their formation as a consequence of transpeptidation cannot be ruled out on the basis of these results alone. In this connexion a peptide of the composition Arg.(Asp,Ala$_2$,Ileu,Lys).Lys.Tyr was isolated from a *chymotryptic* hydrolysate of the proteins, and since this peptide contains all the amino-acids of peptide Tryp-11, the presence of the latter in tryptic hydrolysates is probably not attributable to transpeptidation.

It should be noted that Tryp-10, isolated in a yield of only 7 per cent (cf. Table 2), is not derived from a unique, unaccounted portion of the amino-acid sequence, since its inclusion as such would necessitate the assignment of a fifth proline residue to the composition of myoglobins IV and V (cf. Table 1). If peptides Tryp-10, -11, -12 and -19 are excluded, the soluble peptides collectively account for 107 residues, including 16 of the 19 residues of lysine and 3 of the 4 residues of arginine.

When the insoluble fraction was exposed to trypsin a second time, small but significant changes were detected in its composition. However, the com-

Table 2. AMINO-ACID COMPOSITION OF SOLUBLE PEPTIDES OBTAINED FROM MYOGLOBINS IV AND V AFTER DEGRADATION WITH TRYPSIN

The composition of each peptide is presented in terms of the molar ratios of the constituent amino-acid residues. The peptides were isolated by ion-exchange chromatography on a series of columns of 'Amberlite *IRC*-50' and 'Dowex 50-*X*2'. The values for the principal components in each peptide are in black type. Values less than 0·01 unit are omitted from the table. The values in parentheses are not included in the totals

Amino-acid	Peptide																					Total No. of residues from peptides Tryp 1–21

position was not markedly affected by additional exposures to the enzyme. After exhaustive treatment with trypsin, the insoluble fraction ('core') was subjected to amino-acid analysis, from the results of which the following overall composition of the fraction was deduced:

$$\text{Asp}_2,\text{Glu}_6,\text{Gly}_4,\text{Ala}_5,\text{Val}_6,\text{Leu}_7,\text{Ileu}_4,\text{Ser}_3,\text{Thr},\text{Phe},\text{Tyr},\text{Try}_2,\text{His}_4,\text{Lys}_3,\text{Arg}.$$

This composition was not markedly altered when the insoluble fraction was subjected to the action of chymotrypsin.

The combined analytical results obtained from the soluble and insoluble portions of the tryptic hydrolysate indicate that all the amino-acid residues in the protein, with the exception of one histidine and one leucine residue, were identified as constituents of the peptides. Collectively, these peptides contain six additional residues (Asp_2,Glu,Gly,Ala_2) not assigned to the composition of myoglobins IV and V. It is probable that these additional residues are present in sequences accounted for by both the insoluble fraction and one or more soluble peptides.

The hæm group apparently does not shield the insoluble fraction from the action of trypsin. The composition of the insoluble fraction from a tryptic hydrolysate of urea-denatured globin prepared from myoglobins IV and V was found to be almost the same as that of the insoluble fraction from myoglobins IV and V.

End-group Analyses

Prior to further fractionation, the homogeneity of the peptide material represented by the insoluble fraction ('core') was investigated by end-group analysis. Both the insoluble fraction, and for comparison, the intact protein were subjected to dinitrophenylation by Levy's method[11]. After acid hydrolysis of the dinitrophenyl (DNP) derivatives, a single amino-terminal residue of valine was detected in each case by a combination of the following methods: identification of DNP-valine by paper chromatography[12]; quantitative determination of the valine liberated from DNP-valine by alkaline hydrolysis[13]; and a subtractive procedure in which each polypeptide was subjected to quantitative amino-acid analysis[14] before and after dinitrophenylation. The presence of one DNP-valine residue in the insoluble fraction indicates that the insoluble fraction contains either one peptide with a valine terminal group, or several peptides, one of which possesses a valine end-group, whereas the others have end-groups that were not detected by the procedure used. In the accompanying paper Kendrew *et al.* have deduced that the 'core' must consist of at least two peptides.

Since peptide Tryp-18 is the only soluble peptide containing valine, it was subjected to sequential degradation by Edman's method[15], and the results were compared with those obtained when the protein was subjected to the same procedure. The amino-acids cyclized off at each step were identified by a subtractive method[16], alone or in combination with paper chromatographic identification[17] of the corresponding phenylthiohydantoins. The sequence valylalanine (Val.Ala) was found at the amino-end of the protein, whereas in peptide Tryp-18 the corresponding sequence was found to be valylglutaminylalanine (Val.Glu-NH_2.Ala). The valine terminal peptide in the insoluble fraction thus represents the amino-terminal region of the protein.

The identities of the amino-terminal residues in peptides Tryp-9 and Tryp-21, and the amino-acid sequences in peptides Tryp-1, Tryp-2, Tryp-4, Tryp-5, Tryp-13, Tryp-14, Tryp-15, Tryp-16 (the carboxyl-terminal peptide in the chain), Tryp-17, and Tryp-20 were established by Edman's method. The sequences found are shown in Table 3.

Table 3

Peptide	Sequence
Tryp-1	Ala.Leu.Glu.Leu.Phe.Arg
Tryp-2	Phe.Asp.Arg
Tryp-4	Ala.Thr.Lys
Tryp-5	Leu.Phe.Lys
Tryp-9	N-terminus: Gly
Tryp-13	His.Leu.Lys
Tryp-14	Asp.Ileu.Ala.Ala.Lys
Tryp-15	Ala.Ser.Glu.Leu.Asp.Lys
Tryp-16	Glu.Leu.Gly.Tyr.Gly.Glu-NH_2
Tryp-17	Thr.Glu.Ala.Glu.Met.Lys
Tryp-20	Ser.His.Pro.Glu.Thr.Leu.Glu.Lys
Tryp-21	N-terminus: His

Glutamine, glycine and tyrosine were the principal products liberated from both Tryp-16 and the globin derived from the intact protein by the action of carboxypeptidase *A*, whereas leucine and glutamic acid, as well as alanine, *iso*leucine, threonine and aspartic acid, were released in smaller quantities from the protein. The quantitative similarity in the pattern of release of the principal products liberated in each case substantiates the conclusion that peptide Tryp-16, the only peptide devoid of lysine and arginine, represents the carboxyl-terminal region of the protein.

Work is now in progress on the peptides liberated by the action of chymotrypsin from myoglobins IV and V in order to obtain the information necessary for the connexion, in sequence, of the tryptic peptides along the polypeptide chain.

This work was initiated at the Rockefeller Institute in the laboratories of Dr. S. Moore and Dr. W. H. Stein, to whom we are indebted for their advice and encouragement. Research at Brookhaven National Laboratory was performed under the auspices of the United States Atomic Energy Commission. The work of one of us (A. B. E.) at Cambridge has been facilitated by grants from the United States Public Health Service for a fellowship and for provision of an amino-acid analyser (grant Nos. *A*–3032 and *A*–3032(S1)). We thank Dr. J. C. Kendrew for his continued support of this research and Mrs. Margaret Ross for her skilled assistance.

A Partial Determination by X-ray Methods, and its Correlation with Chemical Data

By Drs. J. C. KENDREW, F.R.S., H. C. WATSON, B. E. STRANDBERG and R. E. DICKERSON
Medical Research Council Unit for Molecular Biology, Cavendish Laboratory, Cambridge
AND
D. C. PHILLIPS and V. C. SHORE

An earlier article in *Nature*[1] described the general features of the 2-Å. Fourier synthesis of sperm whale myoglobin, and showed that the molecule consists of a number of segments of right-handed α-helix separated by irregular regions. In that article doubts were expressed about the possibility of identifying side-chains in a Fourier synthesis calculated at 2-Å. resolution, at which neighbouring covalently bonded atoms are generally not separately resolved. Interpretative techniques have now been improved, however, and it has, in fact, proved possible to identify many side-chains with assurance, and in many others to narrow the choice to two or three. To determine completely the amino-acid sequence of a protein by X-ray methods alone, it will clearly be necessary to work at higher resolution than 2-Å., as we intend to do in future studies of myoglobin; but in the meantime it has been possible, by correlating the present X-ray identifications with the preliminary chemical results, described in the preceding article by Edmundson and Hirs, to arrive at a tentative amino-acid sequence which, though it is incomplete and contains ambiguities and no doubt some errors, cannot be very far from the truth.

Methods of Identifying Side-chains

The Fourier synthesis is normally represented as a stack of contoured 'Perspex' sections representing the electron density in a series of parallel planes cut through the molecule. The previous article described another method of representation, more convenient for model-building, in which the main features of the density at a grid of points in the structure are represented by coloured clips attached to vertical steel rods; the structure of the molecule can be outlined by building skeleton-type atomic models between the rods in such a way that they follow the density indicated by the clips. With the help of this technique, it was easy to locate all the helical segments of the molecule, and, with somewhat less assurance, to follow the course of the main chain in non-helical regions where it turns corners. Once the main chain has been correctly inserted, the density corresponding to the side-chains can easily be seen emerging from it at the appropriate intervals. It is now often possible to identify side-chains by building atomic models between the rods so as to follow the density, and checking the results by reference to the more detailed information in the contour map itself. We have also made use of special sections cut through the density distribution at any desired angle and position; these sections are prepared by interpolation from the original density function by means of a computer programme, devised for *Edsac* Mk. II by Dr. Joyce Wheeler.

Methods of identification can be summarized as follows:

(1) Once the course of the main chain has been established, the starting point of each side-chain becomes defined, since the position of Cβ is fixed relative to the main chain.

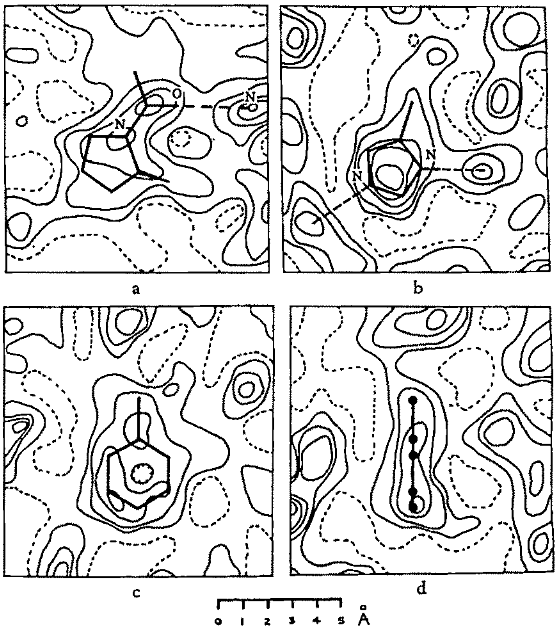

Fig. 1. Sections through parts of the 2-Å. Fourier synthesis showing side-chains. Contour interval 0·5 el./Å.^{3}: atoms not otherwise labelled are carbons. (*a*) Proline, *F*3. The dotted line is a hydrogen bond from the CO group to a NH group along the helix. (*b*) Histidine, *C*1. The dotted lines indicate hydrogen bonds to neighbouring groups, probably ions or water molecules. (*c*) Phenylalanine, *B*14. Note that there is no density peak within Van der Waals distance of the ring atoms. (*d*) Phenylalanine *B*14. Section cut normal to the plane of the ring

(2) Studies of the structures of simpler compounds by X-ray and spectroscopic methods have led to the generalization that, unless strong interactions elsewhere in the molecule impose restraints, the arrangement of the bonds about a singly bonded pair of carbon atoms is always very close to the staggered configuration, the eclipsed configuration being, energetically, relatively unfavourable. A detailed examination of the published structures of amino-acids and peptides (F. H. C. Crick, personal communication) shows that this generalization is applicable to such compounds. We have made the assumption—which our experience here justifies—that, unless there are over-riding reasons to the contrary, the staggering rule is everywhere obeyed within ± 10–15°. It means, for example, that when the Cβ of a side-chain has been correctly placed, only three positions are open to Cγ's, and a search for density can be made in each of these positions in turn.

We have assumed, furthermore, that, in the absence of contrary reasons, such as an interaction with nearby groups, a long side-chain such as lysine is normally in the fully extended (zig-zag) configuration.

(3) Steric considerations are often important in ruling out certain configurations. Thus, in helical

x, discrepancies between X-ray and chemical data. *a*, terminal amino-group. *b*, terminal carboxyl-group. *c*, bonded to propionic acid side-chain of hæm group. *d*, Attached to iron atom of hæm group.

X-ray data. The degree of confidence in each identification is indicated by a number, with maximum confidence represented by 5. Where a choice of residues is given, that which agrees with the chemical evidence is printed in Roman type, the others in italic type. '*β-f*' means a residue forked at C*β*, that is, Val, Thr or Ileu.

Residues are identified by a letter, or letters, and a number. A single letter refers to one of the helical segments *A–H*; a double letter to an irregular region between two helices. A residue is counted as part of a helical segment (*a*) at the amino-end, if its CO group is bonded to NH along the helix, and (*b*) at the carboxyl end, if its Cα lies between two NH groups bonded to CO groups along the helix.

Chemical data. The numbers in black type are those used by Edmundson to identify tryptic peptides.
Boxes enclose residues the sequence of which has not been chemically determined.
Tryptic peptides believed (on the basis of chymotryptic digestion) to be linked together are so indicated.
Asp.C and Glu.C refer to the acids and Asp.N, Glu.N to the amides.
Peptides the positions of which in the sequence are regarded as doubtful are printed in italics.

The only tryptic peptide isolated by Edmundson and Hirs which is not accounted for in this scheme is **10** (Ala, Leu, Pro) Lys; it is believed on chemical grounds that this residue may be an artefact.

segments, one of the three Cγ positions permitted by the staggering rule is sterically impossible, because an atom in that position would be too close to a carbonyl oxygen atom in the helix. Again, the close-packed internal structure of the molecule means that neighbouring side-chains are generally in contact; often the configuration of one side-chain which has been unambiguously established imposes limitations on nearby side-chains which help in their identification.

(4) Forking of the density in a side-chain can often be clearly seen, and the position of the fork greatly aids identification. Thus a side-chain forked at Cβ must be valine, threonine, or *iso*leucine; a side-chain forked at Cγ must be leucine, aspartic acid or a ring. The shape of the density at the fork is also diagnostic; thus tetrahedral forking at Cγ can only be leucine, while a planar fork must mean aspartic acid or a ring. Ring side-chains (His, Phe, Tyr, Try) can most easily be identified by means of special sections cut in their plane; some examples of these are shown in Fig. 1.

(5) Threonine and *iso*leucine possess a second asymmetric carbon atom, of known absolute configuration. This provides a valuable check on the identification of these two amino-acids.

Some ambiguities remain even when all these methods have been applied. For example, threonine and valine, glutamic acid and glutamine, aspartic acid and asparagine, cannot be distinguished by shape alone; and leucine and aspartic acid, histidine and phenylalanine, are often difficult to distinguish at the present resolution. It is sometimes possible, however, to discriminate between these pairs by looking for interactions with nearby groups. Thus threonine, aspartic acid and histidine can interact with neighbours by means of hydrogen bonds or salt bridges, while valine, leucine and phenylalanine cannot approach nearby groups more closely than is permitted by Van der Waals contacts, which are definitely longer (see, for example, Fig. 1). Another difficulty arises from the fact that a side-chain can sometimes assume two alternative configurations between which it is statistically distributed in different molecules in the crystal. Thus we have found several lysines which can interact with either of two nearby groups, each configuration being correctly staggered; such a lysine appears to be branched and may easily be mistaken for a forked side-chain. Quite apart from these difficulties, the experimental errors inherent in the present Fourier synthesis often make identification difficult; these errors are particularly large near the sites of heavy-atom substitution. Identification is also more difficult in the non-helical parts of the molecule, where the configuration of the main chain is difficult to establish with certainty; and it is difficult to identify side-chains, especially longer ones, which stick out of the molecule into the ambient solution, presumably because they can assume several alternative configurations.

The process of identifying side-chains involves locating precisely, first the main chain atoms to which the side-chains are attached, and secondly, the atoms of the side-chains themselves. These atomic co-ordinates will also be required for structure factor calculations in refining the structure at higher resolution. In all, we have located with reasonable precision (~½ Å.) 634 atoms in helical regions of the main chain and in the hæm group, and 262 atoms in side-chains which have been identified fairly definitely; excluding hydrogens the molecule contains a little more than 1,200 atoms, so, at a conservative estimate, it should be possible to include in the initial structure factor calculations some 75 per cent of the atoms in the structure.

Correlation between X-ray and Chemical Data

Column 1 of Table 1 summarizes the results of a detailed survey of the side-chains, our degree of confidence in each identification being indicated numerically. In all, 151 residues have been located, whereas the chemical analysis indicates a total of 153. There are eight segments of α-helix, indicated by the letters *A–H*; these are separated by non-helical regions *AB*, *CD*, *EF*, etc. So far as we have been able to determine, all the α-helical segments are straight and regular with the exception of *E*, which has a slight but definite bend in the middle.

In column 2, all sixteen tryptic peptides identified by Edmundson and Hirs (see previous article) have been placed alongside corresponding regions of the polypeptide chain, four of them with less confidence than the others. In general, the composition of each peptide determined from the model agrees with that found chemically, as does the sequence (wherever it has been established by Edmundson and Hirs), and the preliminary evidence which they have obtained from the chymotryptic digest as to the order in which the tryptic peptides are connected is confirmed by our placing. Once the peptides have been placed, their known chemical compositions can be used to discriminate between alternative X-ray identifications of particular side-chains, but there remain a few absolute discrepancies which are indicated in Table 1; it must be emphasized that both the X-ray and the chemical data are preliminary, so that some discrepancies and errors

Table 2

	Total composition				Core	
	X-ray identification			Chemical	X-ray	Chemical
	(*a*)	(*b*)	(*c*)			
Gly	8	9	11	11	3	3
Ala	13	14	17	17	3	3

Tyr	3	3	3	3	1	1
Try	2	2	2	2	2	2
Met	2	2	2	2	—	—
Unallocated			9		4	
Totals	78	97	151	153	45	44–46

(*a*) Identified with confidence 5 or 4 (see notes to Table 1) from X-ray data alone.

(*b*) *a*+residues identified from X-ray evidence with help from composition of tryptic peptides which can be placed with confidence (ordinary type in Table 1).

(*c*) Best allocation of residues, taking into account overall chemical composition as well as chemical evidence included under *b*.

Notes. (i) In the allocations in columns *b* and *c*, there are: 16 residues where chemical evidence has been used to select from two equally probable X-ray identifications; 8 residues where chemical evidence has been used to select a less probable from two or more X-ray identifications; 6 residues allocated purely on the basis of chemical evidence (no identification possible from X-ray evidence); 4 absolute discrepancies between X-ray and chemical evidence (see Table 1).

(ii) The figures in columns (*a*) and (*b*) are often reduced by difficulties in distinguishing particular pairs; thus if Val and Thr are taken together, the figures are *a* 8, *b* 11, *c* 11 (chemical analysis, 13).

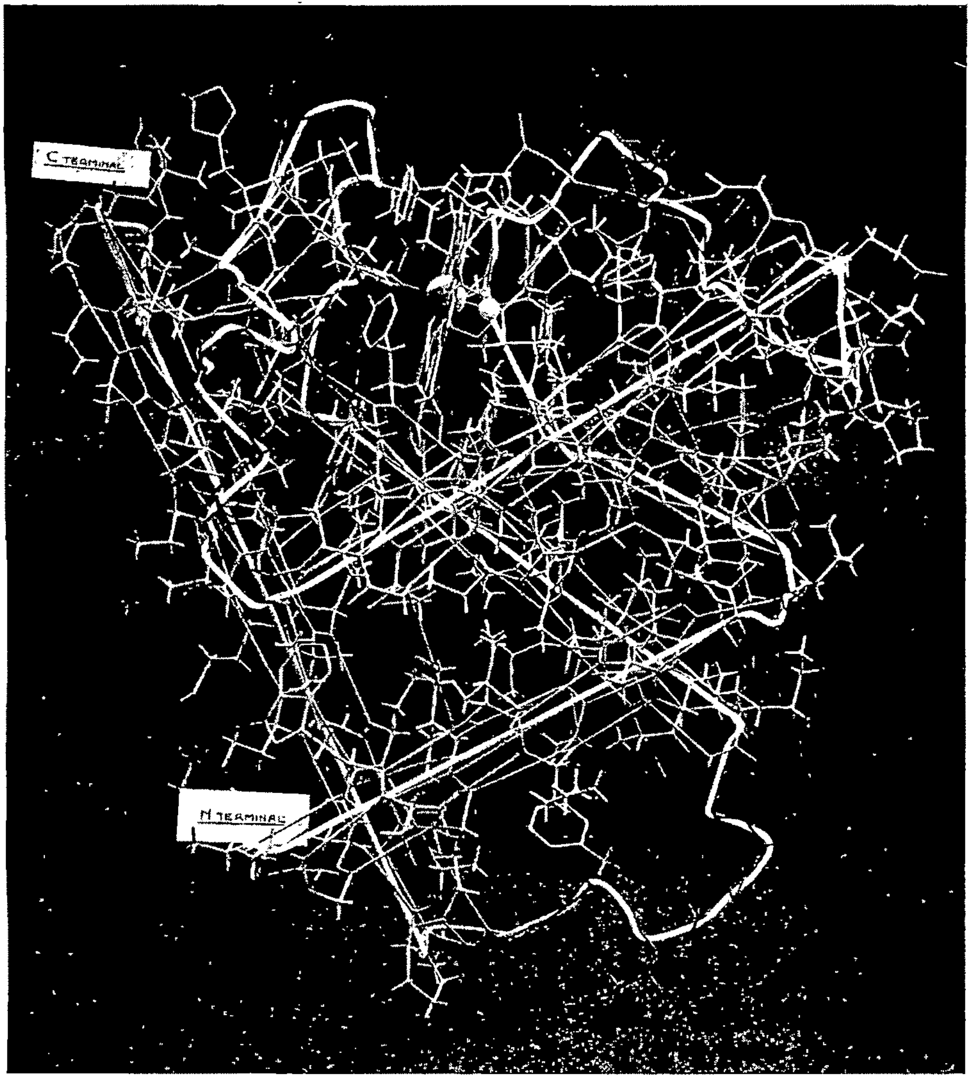

Fig. 2. Model of the myoglobin molecule, including side-chains. The course of the main chain is indicated by a white cord, the N-terminal and C-terminal residues being marked. The iron atom is shown as a grey sphere; the nearby white sphere is a presumed water molecule co-ordinated to it

must be expected. The overall agreement between the X-ray and chemical data as regards total amino-acid composition is summarized in Table 2.

In many cases our assignment of tryptic peptides to particular regions of the sequence was made in advance of more detailed chemical evidence obtained later by Edmundson and Hirs, which in all cases confirmed the assignment. Thus, the sequence of the residues within peptides 11, 15, 17 and 20 was determined chemically after these peptides had been placed as indicated in Table 1; again, the evidence from chymotryptic digestion suggesting the peptide sequences 1–11–8–16 and (part of core)–20–2–6 was not known to us at the time these peptides were similarly arranged on the basis of X-ray evidence.

One major problem concerns the placing of the so-called core, which we have tentatively assigned to the regions indicated in Table 1. As shown in the preceding article by Edmundson and Hirs, tryptic digestion leaves an insoluble core of 44–46 residues. By the usual tests the core possesses a single terminal amino-group which corresponds to that of the intact molecule; accordingly we tried to fit it to the first 44–46 residues (from *A*1 to about *CD*5) at the amino-end of the chain. This arrangement led to several difficulties, however. Thus, the overall composition of this region, determined from the model, does not correspond to that of the core; again, no satisfactory places can be found for peptides 20, 2 or 6; and finally, residue *C*2, which is only 35 places from the end of the chain, is almost certainly proline, an amino-acid which the core is believed to lack. These difficulties could be resolved if it was assumed that the core consisted of two parts, one comprising residues *A*1–*B*15, and the other residues *G*4–*G*16. The total composition of these regions agrees rather well with that of the core (see Table 2); peptides 20, 2 and 6 can be placed naturally from *B*16 to *CD*5 inclusive, and the sequence (part of core)–20–2–6 agrees with Edmundson and Hirs's deductions from the chymotryptic digest; on the other hand, we meet a new and still unresolved difficulty, namely, as yet there is no chemical evidence of a second amino end-group in the core. We may also ask why, if the core indeed consists of two fragments, these should remain stuck together during prolonged digestion. It may be noted that in the intact molecule the two regions assigned to the core pass close to one another, and it may be that some unusual type of chemical bond is involved (we have in fact observed a continuous bridge of high electron density between residues *A*11 to *G*16 which might conceivably include such a bond).

Some Features of the Structure

Fig. 2 is a photograph of a model of the molecule, including side-chains and viewed from about the same angle as Fig. 5 of the previous article[1].

Corner turning. The molecule contains eight non-helical regions, one of which consists of four residues at the carboxyl end of the chain, while the others form corners between lengths of helix. Each corner is different from every other, and the numbers of residues contained in them varies from 0 to 8. It is well known that proline cannot be inserted into an α-helix except at its amino-end, so it is not surprising to find that all four prolines in the molecule are in different corners at the last turn of a helix; one of these corners (*BC*) is very elegant, in that it contains no non-helical residues—every residue forms part of either helix *B* or helix *C*. (Another corner which contains no non-helical residues is *DE*, but there is no proline in this region.) Two other types of interaction, which are evidently important in determining the configuration of a corner, have been observed: (1) the hydroxyl group of serine (*E*1) or threonine (*D*1) hydrogen-bonding to a free peptide imino-group at the amino-end of a helix, and (2) a lysine (*B*7), which originates from quite a different part of the molecule, bonding to a free peptide carbonyl group in corner *DE*. It is by no means obvious, however, what interactions are primarily responsible for the existence of several of the corners. The three-dimensional configuration of a protein is presumably determined by the position and nature of the corners, and eventually one might hope to be able to deduce these from a study of the amino-acid sequence. The variety and complexity of the non-helical regions in myoglobin suggest, however, that this will be by no means a simple matter.

Environment of the hæm group. It is nearly certain that the group which links the iron atom to the protein is histidine (*F*8). On the distal side of the iron atom is a single peak, presumably a water molecule; beyond this is a side-chain (*E*7) which is probably histidine or perhaps glutamic acid (or glutamine). As might be expected, the polar propionic acid groups lie on the outside of the molecule, one probably linked to arginine (*CD*3); on the other hand, the non-polar vinyl groups are buried deep in the interior. The whole inner part of the hæm group is surrounded by non-polar side-chains, and it is noteworthy that there is a large concentration of aromatic side-chains in the general neighbourhood of the hæm group.

General distribution of side-chains and liquid. There is a tendency, perhaps less marked than might have been expected, for polar side-chains to project outwards from the molecule and for non-polar ones to be buried within it; 30 per cent of the polar and 45 per cent of the non-polar residues are buried. This tendency is much more obvious in certain side-chains, especially larger ones; thus all the phenylalanines and methionines are internal, and almost all the lysines, arginines and glutamic acids are external. On the other hand, most of the non-polar alanines project outwards.

Nearly all polar groups, including peptide carbonyl and imide groups, interact either with nearby groups or else with isolated peaks which must be water molecules or ions. Most of these isolated peaks are external; there are, apparently, a few water molecules within the protein molecule, but for the most part the protein is close-packed with little internal free space. The ambient fluid is 4 *M* ammonium sulphate; it is probable that the lattice contains 20–30 ammonium sulphate molecules per myoglobin molecule. Ammonium ions would be indistinguishable from water molecules at the present resolution; on the other hand, sulphates would appear as dense peaks if they occupied defined positions in the lattice. We have actually observed only two or three peaks on the surface of the molecule which are dense enough to be certainly sulphate ions; the fact that the other sulphate ions are not observed suggests that most of them, together with the water in which they are dissolved, are distributed at random.

We wish to thank the Director of the Mathematics Laboratory, University of Cambridge, for facilities on *Edsac* Mk. II: the Rockefeller Foundation for generous financial support; the National Science Foundation (U.S.A.) and National Institutes of Health (U.S.A.) for providing fellowships for one of us (R. E. D.); Dr. Joyce Wheeler for preparing *Edsac* programmes used in making special Fourier sections; Miss Mary Pinkerton, Mrs. J. Blows, Mrs. V. Cotterill, Miss J. Leeland, Mr. P. Mulhall and Miss E. Rowland for assistance in model building and in other ways.

Comparison Between the Amino-Acid Sequences of Sperm Whale Myoglobin and of Human Hæmoglobin

By Drs. H. C. WATSON and J. C. KENDREW, F.R.S.

Medical Research Council Unit for Molecular Biology, Cavendish Laboratory, Cambridge

PERUTZ *et al.* have shown that the tertiary structures of the α- and β-chains of horse hæmoglobin closely resemble those of sperm whale myoglobin[1]. One might predict that there would be correspondences between those side-chains, the specific interactions of which are responsible for the tertiary structures of the three types of chain, and for the closely similar reactions of the two proteins with oxygen and other ligands, even though there are substantial differences between their overall amino-acid compositions. Unfortunately, the amino-acid sequence of horse hæmoglobin has not yet been determined, but most of that of human hæmoglobin has recently been established by Braunitzer *et al.*[2,4],

Notes. The amino-acid sequence given for myoglobin is that which is considered to be the most probable on the basis of X-ray and chemical evidence.

Non-ordered regions of the hæmoglobin chains are enclosed in boxes.

Corresponding residues in the ordered regions of the chains are italicized; but all prolines are printed in heavy type.

Substitutions: in the α-chain, hæmoglobin *I*: Asp at (*a*), ref. 6; Norfolk: Asp at (*b*), ref. 7; *M* (Boston): Tyr at (*c*) (Gerald, P. S., Efron M. L., Jones, jun., S. H., and Pisciotta, A. V., personal communication); *G* (Philadelphia): Lys at (*d*), ref. 8. In the β-chain, hæmoglobin *S*: Val at (*e*), ref. 6; *C*: Lys at (*f*), ref. 6; *G* (San José): Gly at (*g*), ref. 6; *E*: Lys at (*h*), ref. 6; *M* (Emory): Tyr at (*i*) (Gerald, P. S., Efron, M. L., Jones, jun., S. H., and Pisciotta, A. V., personal communication); *M* (Milwaukee-1): Glu at (*j*) (Gerald, P. S., Efron, M. L., Jones, jun., S. H., and Pisciotta, A. V., personal communication); *D* (Punjab) (= *D*): Glu.N at (*k*) (Baglioni, C., personal communication). In the δ-chain: Thr at (*l*), ref. 9; Asp at (*m*), ref. 9; Ala at (*n*), ref. 9; Ser at (*o*), ref. 9.

by Hill and Konigsberg[5], and by Schroeder and Jones, and it is reasonable to expect correspondences here, too, in view of the accumulating crystallographic evidence that the tertiary structures of hæmoglobins and of myoglobins of different species are very similar.

In Table 1 the human hæmoglobin chains have been placed alongside that of myoglobin (see preceding article by Kendrew *et al.*) in what seems to us the most plausible manner. The chains differ in length (myoglobin 151–153 residues, hæmoglobin α-chain 141 and β-chain 150 residues), and in comparing them we have tentatively assumed that interpolations or deletions occur only in or near inter-helical regions, since even a single change of this kind in the middle of a helix would completely alter the environments of all the side-chains on at least one side of the change. There are substantial regions in both hæmoglobin chains where the sequence of residues has yet to be determined; in each non-ordered region, we have arranged residues so that, where possible, amino-acids coincide with identical residues in the other hæmoglobin chain; where that cannot be done, or where corresponding regions in both hæmoglobin chains are non-ordered, the hæmoglobin residues have been arranged so as to correspond as nearly as possible to residues in the myoglobin chain. The fourth column of the table indicates those regions of the myoglobin chain which are α-helical (for terminology see Table 1 of the preceding article); the first column contains a numbering system which will be used for reference in the present article.

The tentative scheme in Table 1 leads to the following conclusions:

(1) All the prolines in the α- and β-chains can be placed so as to lie at the open end of a helix or in a non-helical region; wherever proline occurs in myoglobin, a proline can be correspondingly placed in both α- and β-chains. Sharp corners (that is, with few or without non-helical residues) do not, however, require the presence of proline; corner *AB* is without proline in any of the three chains, and *DE* has no proline in myoglobin, although it apparently has the same shape in the β-chain[1], which has proline at this position.

(2) Side-chains, the identities of which in myoglobin appear to be determined by specific interactions or steric features, often have counterparts in the hæmoglobin chains. Thus, at residues 26 and 66, helices *B* and *E* approach one another so closely that no side-chain larger than glycine would be possible; glycine is found in each position in all three chains. Residue 65 in myoglobin is probably histidine, and if so is within hydrogen-bonding distance of a water molecule attached to the sixth co-ordination position of the iron atom; histidine appears at the same position in both hæmoglobin chains. (The hæm-linked residue in myoglobin is also histidine, residue 98. Unfortunately, the corresponding region of one of the two hæmoglobin chains is still non-ordered; it is, however, possible to place histidines in position 98 in both α- and β-chains.) In myoglobin, the tyrosine at residue 152 forms a hydrogen bond with the main-chain carbonyl group of residue 105, presumably acting as a stabilizing bridge between the ends of the long helices *G* and *H*; tyrosines occur in the corresponding places in the α- and β-chains.

(3) The two hæmoglobin chains, unlike that of myoglobin, each has a small non-helical tail (2 residues in the α-chain, 3 in β-) at the amino-end, helix *A* being terminated at the proline in position 5. On the other hand, the non-helical tail at the carboxyl end of the myoglobin chain is absent from both hæmoglobin chains. Furthermore, in the α-chain of hæmoglobin (but not in the β-) six residues are missing between residues 42 and 59, that is, in the region near the short helix *D*. Inspection of Perutz's 5·5-Å. model of horse hæmoglobin confirms that in the α-chain the loop between 42 and 59 is shorter than in myoglobin or in the β-chain; this model also confirms that a 'tail' is present at the amino-end, and absent at the carboxyl-end, of each chain (Perutz, personal communication).

(4) Several of the substitutions which have been located in the δ-chain of hæmoglobin A_2 and in the abnormal hæmoglobins are indicated in Table 1. In nearly all cases these residues stick outwards from the molecule, so substitutions would not be expected to affect the tertiary structure. The only exceptions are the change from Thr to Ser at residue 52 in the δ-chain and the very interesting hæmoglobin *M* substitutions. The former residue is important in terminating helix *D* (see preceding communication), and is Ser in α and δ, and Thr in β and myoglobin. The characteristic abnormality of hæmoglobin *M* is an unusual difficulty in reducing the ferric to the ferrous form; in two variants we find that His has been converted to Tyr, in one case on the α-chain and in the other on the β-chain, at residue 65, which is located close to the iron atom opposite the hæm-linked histidine (see (2) above). In the third variant, Val at residue 69 becomes Glu; this residue is also very close to the iron atom.

If non-ordered residues in the hæmoglobin chains are disregarded, there are 50 possibilities for triple correspondences (identical residues in corresponding positions in all three chains)—only 10 (20 per cent) are observed. There are 54 possibilities of double correspondences between α- and β-, of which 26 (48 per cent) are observed; on the other hand, of 70 possible double correspondences between α- and myoglobin, only 20 (28 per cent) are found, and of 91 between β- and myoglobin only 25 (28 per cent). The main impression is that in spite of presumed close resemblances in tertiary structure, the correspondences are remarkably few. It must be concluded from this and the preceding article by Kendrew *et al.* that the crucial interactions which determine the tertiary structure of a protein are very complicated and are not confined to the corners between helices; detailed investigations, perhaps including comparisons between related proteins, will be necessary before general principles become apparent.

We thank Dr. M. F. Perutz for valuable discussions; also Drs. V. M. Ingram, Park S. Gerald and W. Konigsberg for a discussion of the (unpublished) proceedings of the Hæmoglobin Structure Workshop at Endicott House on December 14–16, 1960.

THE ENGINEER IN COMMONWEALTH DEVELOPMENT

A LITTLE reflexion might suggest that it is perhaps a strange way to honour the achievements of distinguished men by inviting them to accept a presidency which involves a presidential address before a distinguished, but highly critical, audience or to give a named lecture which, because of the special circumstances, likewise attracts wide publicity. Many a famous scientist has emerged from such an ordeal with an impaired rather than an enhanced reputation; the specialist venturing outside the sphere in which he is an acknowledged master is too often apt to be trite or banal. On the other hand, such an occasion affords a great opportunity to present to an influential audience a considered synthesis which may well bear important fruit.

H.R.H. the Duke of Edinburgh is one who rises magnificently to such occasions. No one who heard his presidential address to the British Association at Edinburgh in 1951 could doubt his ability to take the broad, balanced view, based with meticulous care on carefully collected and assimilated facts, and to present his material in such a way as to shame the professional lecturer. This year he was invited jointly by the three great engineering institutions—the Civil, Mechanical and Electrical—to give the seventh Graham Clark Lecture on April 13. The first plan was a survey of "Resources, Human and Material, of the Commonwealth". The basic material was assembled and has been published as a series of statistical tables separately printed as appendixes to the lecture. A wide range of standard sources—in each case the best available—has been used and combined with the results of a number of specific inquiries (especially through the Commonwealth Economic Committee). Throughout these tables the emphasis is on a comparison between the Commonwealth (with countries separately named but including at this date the Union of South Africa) and the world as a whole. Population, labour force, land use, value of agricultural produce, energy production and consumption, primary production, mineral output, mineral reserves, transport and education are included in turn. The whole affords a simple yet effective view of how the Commonwealth stands in relation to the world as a whole.

But, as the Duke so rightly says, "resources are not very interesting until you start doing things to them". Since engineers play a dominant part in this, "I have tried to outline the engineer's part in the various fields of development and some of the opportunities and problems" of the profession. "The engineer is in fact the means by which the people are able to enjoy the fruits of science, whether in building new projects, or in maintaining and keeping up to date what is already in existence."

It is rumoured that the presidential address to the British Association was composed—and that is the right word—on the backs of naval signal forms during moments of hard-earned leisure in the chart room or on the bridge of a ship of the Royal Navy on active service. Incredible as it may seem that there were in fact moments of leisure during the recent royal tour to India and Pakistan, by his own confession the Graham Clark Lecture was similarly composed. One result is a particularly felicitous blend of library research and field observations. It may truthfully be said that no living person is better equipped to produce such a survey. No one has travelled the Commonwealth, from Antarctic to tropics, more widely yet always on duty, his hosts ever anxious to show everything worth while, their guest, always alert to note and record, not so much the detail, as the overall picture.

How does the Commonwealth stand in relation to the rest of the world? With 23 per cent of the land surface and 24 per cent of the population, the existence of 44 per cent of the land unused is a challenge since in food production the figures are not impressive. Only rice (24 per cent), barley (20 per cent) and mutton (23 per cent) are produced in proportion to land and population. It is freely admitted that the picture of the Commonwealth as a whole is distorted by the extreme contrasts between its constituent parts such as Britain and India, and the fact that India–Pakistan have 68 per cent of the total people. Nevertheless, the conclusion seems inevitable that the Commonwealth is at present not producing according to potential. 20 per cent of the world's rain falls on Commonwealth lands; Kariba and Volta are projects now in hand but the Hamilton Falls are unused and, taking energy as a whole—coal, oil, water-power—the Commonwealth's share in output is less than 12 per cent.

His Royal Highness comments, somewhat ruefully, that he has to bear criticism rather more frequently than most, and suggests that a little mild and well-intentioned criticism should be treated as a sign-post rather than as a slander. His comments, though forthright, are scarcely criticisms and are so obviously sincere and well-founded as to command respect. There is the old argument involving 'pure' and 'applied' science—by implication the latter also 'impure'—and it is still true that academic honours, for example, the fellowship of the Royal Society, are more hardly won by the applied scientist. Yet who deserves the greater credit: he who conceives an idea in a laboratory or he who with infinite pains adapts and refines it to the benefit of countless numbers of mankind? "We are apt to forget that much scientific research is only possible with the aid of very advanced engineering; computers, electron microscopes . . . are no longer bits of apparatus that can be knocked up in the lab." It is refreshing, too, to be reminded that our united aim should be to benefit mankind. "Unless large-scale projects and modernization plans are based upon a practical humanity they will contribute very little to man's progress." Or again, "it is becoming increasingly popular to look upon industry merely as a convenient way of giving employment . . . it has to satisfy the needs and desires of the individual". It is clear the Duke would not happily agree with those who go so far as to declare that the possession of resources is of little importance compared with the possession of capital with which to develop them. Such a view is economic colonialism at its worst and, by not referring to either political or economic aspects of development, he makes the obvious assumption that mankind should be the master and not the slave of its own social and economic systems.

Coming from a world traveller, we have timely reminders of the importance of communications and of scale so difficult to judge in small countries such as Britain—five times as far across mainland Canada and twice as far from Bombay to Calcutta as from John o'Groats to Land's End.

Seeing the Duke's interest in youth, it is not surprising that he is far from happy regarding the adequacy of higher education in technical fields. The appeal for forward thinking is well timed and, like every other aspects of life brought into this stimulating address, merits the closest attention.

L. DUDLEY STAMP

THE U.S. ACADEMY OF SCIENCES

OFFICERS, MEDAL AWARDS AND NEW MEMBERS

DR. J. A. STRATTON, president of Massachusetts Institute of Technology, has been elected to a four-year term as vice-president of the U.S. National Academy of Sciences. Dr. G. B. Kistiakowsky, Abbott and James Lawrence professor of chemistry, Harvard University, and Dr. Kenneth B. Raper, professor of bacteriology and botany, University of Wisconsin, have been appointed members of Council for a term of three years.

The following medal awards have been made: the *Henry Draper Medal*, for original investigation in astronomical physics, to Dr. Martin Schwarzschild, Princeton University Observatory; the *Daniel Giraud Elliot Medal*, for meritorious work in zoology or palæontology published each year, to Philip J. Darlington, jun., Museum of Comparative Zoology, Harvard University; the *Kimber Genetics Medal*, for achievement in the science of genetics, to Prof. J. B. S. Haldane, (recently) Indian Statistical Institute, Calcutta; the *Jessie Stevenson Kovalenko Medal*, for contributions to medical science, to Dr. K. F. Meyer, George Williams Hooper Foundation, University of California; the *Mary Clark Thompson Medal*, for services to geology and palæontology, to Dr. Norman D. Newell, American Museum of Natural History; the *James Craig Watson Medal*, for noteworthy discoveries or research in astronomy, to Prof. Otto Heckmann, Hamburg-Bergedorf Observatory.

The following new members have been elected: Prof. D. I. Arnon, professor of plant physiology, University of California; Dr. W. O. Baker, vice-president in charge of research, Bell Telephone Laboratories; Prof. S. Benzer, professor of biophysics, Purdue University; Dr. H. A. Borthwick, principal plant physiologist, Agricultural Research Service, U.S. Department of Agriculture; Prof. R. H. Burris, professor of biochemistry, University of Wisconsin; Prof. Shiing-Shen Chern, professor of mathematics, University of California at Berkeley; Dr. P. E. Cloud, jun., chief, Paleontology and Stratigraphy Branch, U.S. Geological Survey; Prof. J. H. Comroe, jun., director of the Cardiovascular Research Institute and professor of physiology, University of California Medical Center; Prof. D. J. Cram, professor of chemistry, University of California; Prof. J. F. Crow, professor of zoology and genetics, University of Wisconsin; Dr. L. S. Darken, associate director, research laboratory, United States Steel Corporation; Prof. C. Djerassi, professor of chemistry, Stanford University; Prof. W. Von Eggers Doering, professor of chemistry, Yale University; Prof. R. Dulbecco, professor of biology, California Institute of Technology; Prof. A. I. Hallowell, professor of anthropology, University of Pennsylvania; Prof. B. L. Horecker, professor of microbiology, New York University College of Medicine; Prof. R. D. Hotchkiss, member, and professor of cellular physiology, Rockefeller Institute; Dr. Libbie H. Hyman, research associate, American Museum of Natural History; Prof. M. G. Inghram, professor of physics, University of Chicago; Prof. W. N. Lipscomb, jun., professor of chemistry, Harvard University; Dr. H. F. Mark, director, Polymer Research Institute, Polytechnic Institute of Brooklyn; Prof. H. Neurath, professor of biochemistry, University of Washington; Prof. G. E. Palade, member, and professor of cytology, Rockefeller Institute; Prof. R. V. Pound, professor of physics, Harvard University; Prof. L. A. Riggs, professor of physiological psychology, Brown University; Dr. R. B. Roberts, chairman, Biophysics Section, Department of Terrestrial Magnetism, Carnegie Institution of Washington; Prof. Per F. Scholander, professor of physiology, Scripps Institution of Oceanography; Dr. C. D. Shane, astronomer, Lick Observatory; Prof. D. C. Spencer, professor of mathematics, Princeton University; Mr. H. M. Stommel, research associate in physical oceanography, Woods Hole Oceanographic Institution; Prof. Leo Szilard, professor of biophysics, University of Chicago; Prof. J. W. Tukey, professor of mathematics, Princeton University; Prof. F. T. Wall, research professor of physical chemistry, University of Illinois; Dr. A. M. Weinberg, director, Oak Ridge National Laboratory; Prof. J. H. Williams, professor of physics, University of Minnesota.

OBITUARIES

Sir William Savage

THE death of Sir William Savage in his eighty-ninth year on April 6, 1961, means the passing of the last survivor of that distinguished company of medical officers of health who contributed so largely to the progress of public health in the late nineteenth and early part of the present century.

William George Savage, the son of John H. Savage, was born in Jamaica in 1872. He was educated privately, at University College, London, and University College Hospital. He took the B.Sc.(Lond.)

in 1894, the M.B.Lond. with honours in medicine and the gold medal in forensic medicine in 1896, the diploma in public health in 1897 and the M.D.(Lond.) in 1898. After a resident post at the Royal Sussex Hospital, he became assistant professor of pathology in University College, London. From 1900–03 he was lecturer in pathology and public health at University College, Cardiff, and during 1903–09 medical officer of health and public analyst, Borough of Colchester. In 1909 he was appointed the first county medical officer of Somerset. Here he did the work that was to make him famous.

Savage was remarkable in that he continued to pursue bacteriological researches which gave him an international reputation, and at the same time administered the public health of his county with conspicuous success.

The organisms present in food poisoning early engaged Savage's attention, and he did research work for the Medical Research Council, partly in collaboration with Bruce White, into the serology of the *Salmonella* groups and their relation to food poisoning (*M.R.C. Reports*, Nos. 91 and 92, 1925). He also showed that domestic animals and vermin were the main reservoirs of these organisms. He made further fundamental studies into food poisoning. In 1940, in a discussion at the Royal Society of Medicine, he gave an account of some original work on *Salmonella dublin*, pointing out that it was responsible for human infection in a number of cases; and as late as 1956 he published a paper with evidence on problems of *Salmonella* food poisoning, and directed attention to the marked increase of food poisoning in Great Britain since the end of the Second World War (*Brit. Med. J.*, ii, 317; 1956).

Savage strongly advocated the pasteurization of milk; he wrote a report on milk and the public health in 1912, and published the following books: *The Bacteriological Examination of Food and Water* (1906), *Rural Housing* (1915), *Food and the Public Health* (1919) and *Food Poisoning and Food Infections* (1920). He was the author of a number of special reports to the Local Government Board, of papers on the prevention of human tuberculosis of bovine origin, on canned foods in relation to health, and on many other scientific subjects, the majority of which were based on his special investigations. He was Milroy Lecturer and Mitchell Lecturer at the Royal College of Physicians, president of the Society of Medical Officers of Health in 1935, examiner in public health for the Universities of London, Wales and Bristol, and received a knighthood for his distinguished services in 1938; in the same year the honorary degree of M.D.(Bristol) was conferred on him.

In 1937, Savage retired from the post of county medical officer but returned to assist in public health work in Somerset during the Second World War. Thereafter he did important work as chairman of the Ministry of Food's Catering Trade Working Party, while his advice and wisdom continued to be sought by other Government departments and public health bodies.

Savage was a strong man both physically and mentally. His interests were many. He played golf and lawn tennis up to an advanced age, was a daring swimmer and a keen gardener. Interested also in history and archæology, in retirement at Winchester, he published an important book, entitled *The Making of Our Towns*, in 1952 based on extensive research, and had been president of the Somerset Archæological Society in 1945. He was a staunch friend, kind and generous to many. Sir William married Mary A. M. Wilson in 1900, and they had a son and daughter. His son, Dr. S. W. Savage, is county medical officer of Warwickshire.

ARTHUR S. MACNALTY

Prof. Gideon Mer, O.B.E.

PROF. GIDEON GERONIMO MER, professor of epidemiology and director of the Malaria Research Station of the Hebrew University of Jerusalem, died on March 23, at the age of sixty-six, in Haifa. To malariologists all over the world he will be remembered for his work on the transmission of quartan malaria, for his method of determination of the age of mosquitoes—a technique now universally adopted in epidemiological studies of insect-borne diseases for a series of lucid papers on the bionomics of *A. elutus*, and for his studies of insecticides in recent years.

Prof. Mer was born in 1894 in Poniewez, Lithuania (at that time part of Czarist Russia). Both his parents were physicians. After graduating from the Real Gymnasium he went, in 1912, to study medicine in Heidelberg. He remained there only two years. At the call of the idealistic youth movement he interrupted his studies and went to Palestine.

At the outbreak of the First World War he was exiled by the Turkish authorities to Egypt. He joined the British Forces, fought in Gallipoli and elsewhere, and later returned to Palestine with the armies of Allenby. After demobilization he directed the first reclamation works in the malaria-infested valleys of Ezdraelon and Jordan.

In 1924, after a brief return to Lithuania, and following a happy marriage, Mer went back to his medical studies. He chose Italy, for he wanted to gain first-hand experience from the famous Italian school of malariologists of Grassi, Marchiafava and Celli. He graduated with honours in 1928, and after spending a year in postgraduate studies at the schools of tropical medicine in Amsterdam and Paris, he returned in 1929 to Palestine to direct the Malaria Research Station of the Hebrew University at Rosh-Pinah-Galilee, where he established free polyclinics for the Arab population of the region and soon was known as 'Hakim el Kabir', beloved and honoured by all.

Mer's research work was done under most difficult and exacting conditions. The experimental transmission of quartan malaria he carried out on himself and on his wife (volunteer Z. M.). The first trials on suppressive treatment of malaria with 'Chinoplasmin' were done in times of strife at the risk of his own life. During these pre-war years he also found time to serve as medical officer to British troops stationed in Galilee, to many of whom his home in the hills became well known.

With the outbreak of the Second World War, Mer volunteered, together with three of his assistants, to H.M. British Forces and commanded a malaria field laboratory in Iran, Iraq and Burma. He was made O.B.E. for his distinguished services and leadership.

After the War, he returned to Israel to use his newly acquired knowledge of modern insecticides for the reclamation of malarious areas. With the establishment of the State of Israel, he served with distinction on many health missions, as head of the Department of Preventive Medicine of the Armed Forces during the war of independence, and for a brief period as director-general of the Medical Services.

MEIR YOELI

NEWS and VIEWS

Assyriology in London :

Prof. C. J. Gadd, C.B.E., F.B.A.

PROF. C. J. GADD, who until his retirement in 1960 held the chair of Ancient Semitic languages and civilizations at the School of Oriental and African Studies, University of London, is certainly the leading Assyriologist in Britain, and one who is very highly esteemed by his colleagues abroad. His work in the field of Sumerian and Babylonian history and literature, as well as in Mesopotamian archæology, has earned him a world-wide—and fully justified—reputation. Born at Bath in 1893, Gadd was educated at King Edward VI School, Bath, and at Brasenose College, Oxford, served in the First World War, and joined the British Museum in 1919 as an assistant keeper in the Department of Egyptian and Assyrian Antiquities—now split into two independent departments, Western Asiatic Antiquities and Egyptian Antiquities. In 1948 he succeeded Sidney Smith as keeper of the Department, a post he held with great distinction until the year 1955, in which he was appointed to his chair at the University, again as the successor of his former colleague, Sidney Smith.

Besides numerous articles in scholarly journals and five volumes in the well-known series, *Cuneiform Texts from Babylonian Tablets in the British Museum*, Prof. Gadd has published several important works, including *A Sumerian Reading Book* (1924), now unfortunately out of print, and *The Stones of Assyria* (1936), a recognized standard book on the history of the first discoveries of Assyrian Palaces. Prof. Gadd has served on the staff of British archæological expeditions in Iraq (Ur, 1923–24; Nimrud, 1952) and Syria (Alalakh-Atshana, 1946). He was chairman of the Assyriological Section of the Twenty-third International Congress of Orientalists when it met at Cambridge in 1954. He was elected a Fellow of the British Academy in 1940, and was made C.B.E. in 1955. Two years earlier, Oxford conferred upon him the honorary degree of doctor of letters, and his former College elected him to an honorary fellowship.

New Chair of Assyriology

A CHAIR of assyriology, as recently established in the University of London, has been long overdue in Britain. 'Assyriology' now includes, by convention, a group of studies concerning ancient western Asia, from the beginnings of civilization in those parts down to about the time of Alexander's conquests. Thus it comprises not only an assortment of languages, by no means all Semitic, but also a diversity of cultures over a span of three thousand years, their bond of union being, in general, the cuneiform script. At their outset these studies owed perhaps most of all to a few men of genius of British birth; yet a chair of assyriology by name has never hitherto existed. The new foundation replaces the former chair of ancient Semitic languages and civilizations.

Prof. D. J. Wiseman

MR. D. J. WISEMAN, the professor-designate, has already a notable career in the learned world. While assistant-keeper in the British Museum he has made his mark as an interpreter of cuneiform texts. From the later period of Babylon and Assyria he has published two sets of historical documents, *Chronicles of Chaldaean Kings* and *The Vassal-Treaties of Esarhaddon*, both with universal acceptance as definitive. From an earlier age and a provincial *milieu* he has made known *The Alalakh Tablets*, a patch of new ground which he opened with great success. Also to his credit are two widely circulated books upon Western Asiatic archæology. All who are interested in the peoples of the Ancient Orient will wish him, with confidence, a tenure of the chair as brilliant as it promises to be long.

Geophysical Research in the Meteorological Office

DR. FRANK STACEY has returned to the United Kingdom from the Research School of Physical Sciences in the Australian National University at Canberra to take up one of the two new Gassiot research fellowships in the Meteorological Office. He has written extensively on geomagnetism and will conduct his future researches from Edinburgh, where he will enjoy the advantages of close association with scientists of allied interests at the University and at Eskdalemuir Observatory near Dumfries. The latter has, for many years, been the centre of geomagnetic work in the Meteorological Office. Dr. H. M. Iyer has been appointed to the other fellowship. Dr. Iyer is at present working at the University of California and will take up his new appointment in the autumn, when he will work from Kew Observatory on the increasingly important subject of seismology.

C.S.I.R.O. Wildlife Survey Section :

Mr. H. J. Frith

MR. H. J. FRITH has been appointed officer-in-charge of the Wildlife Survey Section of the Commonwealth Scientific and Industrial Research Organization (Australia). He succeeds Mr. F. N. Ratcliffe, who resigned last year to become assistant chief of the Organization's Division of Entomology. Mr. Frith graduated in agricultural science from Sydney in 1941. During the rest of the War he served in the Middle East and New Guinea and won a commission. He joined the Organization after his demobilization in 1946 as an assistant research officer at the Irrigation Research Station, Griffith, New South Wales. He remained at Griffith for five years, engaged on horticultural research on citrus problems. He transferred to the Wildlife Survey Section in July 1951. He was originally seconded to the Section to take part in the rabbit surveys associated with the release of the first myxomatosis-infected animals. From 1952 onwards he was able to develop his special interests in birds. He has worked on a number of Australian species, including parrots, pigeons and finches, but his chief subjects have been wild ducks and mallee fowl.

First World Meteorological Day

THE wide scope of the application of meteorological knowledge to agriculture, aviation, shipping, flood protection, water resource questions of many kinds, industry and the activities of the general public is little realized. Still less are the potentialities of warnings issued by the meteorological services of the world appreciated. These warnings are specifically designed to advise aviators, farmers, fishermen, sailors and all those whose work is affected by the weather. The World Meteorological Organization has therefore established the anniversary of the implementation of the Convention of the World Meteorological Organization, March 23, 1950, as World Meteorological Day. The first of these days was celebrated on March 23, 1961. The object is to attract world public interest to the work of the meteorological services and to the assistance they can give. It is also designed to show the need for continuous interchange of meteorological information on a world-wide basis and for meteorological collaboration in other ways, thus demonstrating that the provision of meteorological services in each country is one of the tangible results of day-to-day co-operation between nations. The 109 members of the World Meteorological Organization have been invited to celebrate the World Meteorological Day annually in their country by such means as exhibitions, lectures, visits to national forecasting offices, television and radio coverage.

Experiments on Animals

A BILL, *S*3570, providing for the control of experiments on animals, has recently been introduced in the U.S. Senate. As an aid to its sponsors the secretary-general of the Universities Federation for Animal Welfare, Major C. W. Hume, has submitted a report on the present practice in Great Britain (*Opinions of British Scientists of Home Office Control of Experiments on Animals*. Pp. 8. London: Universities Federation for Animal Welfare, 1961). The report has been based on questions addressed to British scientists who use animals in their experimental work and, with one exception, show that men of science are well content with the present system. They are satisfied that the present system of control and experiment administered by the Home Office does not in any way frustrate experimental work of the highest quality; and they wish to retain Home Office control so that persons without scientific training may not be permitted to experiment on animals without supervision.

Welfare and Care of Laboratory Animals

THE March issue of the *Bulletin of the International Committee on Laboratory Animals* is considerably bigger than some of its predecessors, because it contains, in addition to its usual international news items, a list of corresponding members, notes on the visit of the secretary-general, Dr. W. Lane-Petter, to Norway, the Near East and the U.S.S.R., and a long bibliography of papers on various aspects of research, classified according to the experimental animals used, including invertebrates. The Committee is organizing a symposium on "The Problems of Laboratory Animal Disease", which will be held in Czechoslovakia early in September. The Proceedings of the symposium on "Living Animal Material for Biological Research" have now become available. Full information about the many activities of the Laboratory Animals Centre is given in the *LAC News Letter*, published free in January and July and obtainable, as the other publications mentioned above also are, from the director, Dr. W. Lane-Petter, Laboratory Animals' Centre, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey.

History of Science

THIS new annual review of literature, research and teaching in the history of science is edited by A. C. Crombie (Oxford) and M. A. Hoskin (Cambridge), and published at Cambridge by W. Heffer and Sons, Ltd. There is a board of advisory editors consisting of G. Buchdahl, Herbert Butterfield, F. N. L. Poynter and W. P. D. Wightman. The review will contain critical essays surveying recent work on special topics, and others directing attention to problems for research. There will also be sections devoted to book reviews, surveys of articles of special interest published in other journals, and information about research in progress, teaching and other matters relating to the professional development of the subject. The first number will be published early in 1962.

Queen Victoria Museum and Art Gallery, Launceston, Tasmania

THE recent issues of the *Records* and the annual reports for 1958–59 and 1959–60 of the Queen Victoria Museum and Art Gallery are complementary to each other. They indicate that museums, in addition to a policy for the conservation of objects, are also centres of scholarly research and do their share in the elucidation of scientific, historical and æsthetic problems. The reports are a record of the vigorous activity of the staff in spite of the usual lack of good exhibition and storage space. In accordance with the general policy of widening the contacts of the Museum with the public, display space has been obtained in the central shopping area of the city. This provides accommodation for a series of fortnightly exhibits of special objects as well as the display of notices regarding the activities of the main Museum. The *Records* are concerned with the geology of western and northern Tasmania and deal with both the topography and stratigraphy of the area (New Series. No. 12 : Comments on the Cainozoid History of Western Tasmania. By B. Scott. Pp. 10. No. 13: Erosion Surfaces in Western Tasmania. By B. Scott. Pp. 11. Launceston: Queen Victoria Museum and Art Gallery, 1959 and 1960).

Work in the Antarctic during I.G.Y.

RUSSIAN explorers have been interested in the Antarctic since their first expedition led by F. G. Bellingshausen and M. P. Lazarev during 1819–21. During the International Geophysical Year, when the Antarctic region was studied by a combined effort of twelve nations, the Soviet expedition, centred on the settlement of Mirny, carried out considerable work in this part of the Antarctic continent. In a series of articles published in *Priroda* certain results of this work are given. Thus B. V. Dubovsky (*Priroda*, 7, 45 ; 1960) provides a note on two newly discovered valleys, one called 'The Valley of I.G.Y.' and the other 'Lazarev's trough'. V. D. Novikov (*Priroda*, 8, 43 ; 1960) provides an account of the construction of the scientific base Mirny, which was completed during February 1956, and later of eight additional bases. All these bases provided means of systematic and detailed geological, glaciological and meteorological studies, all of which are briefly described by Novikov. In two articles A. G. Dralkin (*Priroda*, 9, 48 ; 10, 27 ; 1960) describes the Soviet expedition to the South Pole in 1959 and their meeting of the American contingent of the Polar Amundsen-Scott station. The results of the study of the ice sheet and of the

Earth's crust in the Antarctic continent are presented by G. E. Lazarev and S. A. Ushakov (*Priroda*, 12, 17; 1960). These results show that in the eastern Antarctic the average thickness of the ice sheet is not less than 2,000 m. and its maximum thickness 4,000 m. The level of the rock surface below the ice sheet varies from 1,000 m. above sea-level to 800 m. below sea-level. The thickness of the Earth's crust (above 'Moho') is 5–10 km. for the oceanic type, and 25–70 km. for the continental type. The average density of the crust is 2·8. The result of the gravity work is also discussed and it is suggested that the ice load produces a sag in the crust of the order of 600–700 m.

Singing Sand

As the result of deepening the channel of the River Dnieper below the town of Kremenchug a small artificial island of sand was formed. This sand, as described by G. G. Velikii (*Priroda*, 6, 82; 1960), when trodden on emits a singing sound. Neither very dry nor very wet sand will 'sing'. As a rule the sand emits a high pitch in the morning and a lower pitch towards the evening. The 'singing sand' from the Dnieper may thus be compared with the 'musical sand' from the Isle of Eigg in Scotland and other localities.

Rabies in India

THE prevalence of rabies in India is indicated in the report of the Director of the Pasteur Institute of Southern India, Coonoor, for 1959 (Pp. i+116. Coonoor: Pasteur Institute, 1960). During the year, 34,239 courses of anti-rabies vaccine were issued. Of the 35,403 patients treated at the Institute and subsidiary treatment centres during the year, case cards were returned for 15,447 patients. Of these, 9,007 received a complete course of treatment. During the year 980 patients received a complete course of anti-rabies treatment at the Institute itself (968 Asiatics and 12 Europeans). An incomplete course of treatment was also given to 184 patients (Asiatics) of whom 52 were absolved from further treatment after the possibility of rabies in the biting animals had been excluded. One death was recorded among the 1,164 patients who received complete or incomplete courses of treatment giving a mortality-rate of 0·08 per cent. During the period 1907–59, the total number of patients treated at the Institute was 47,197, among whom 417 later died of rabies giving a mortality-rate of 0·88 per cent. Equally encouraging figures are shown by the subsidiary centres where, in 1959, the number of deaths among 8,027 patients who received a complete course of treatment had fallen to 12 (0·15 per cent). Anti-rabies treatment was also made available for the prophylactic treatment of animals. During the 37-year period from 1923 to 1959, 51,382 animals have received anti-rabies treatment, among which 473 deaths have been reported, giving a mortality-rate of 0·92 per cent. The report also describes the routine work and fundamental research into the nature of other diseases carried out at the Pasteur Institute.

Isolation of Malignolipin from Malignant Tumours

KOSAKI and his co-workers isolated a new phospholipid, malignolipin, from human malignant tumours on the basis of its affinity for porphyrin, and found that it was composed of choline, spermine, phosphoric acid and fatty acid; was specific to malignant tumours; and that it promoted intraperitoneal growth of Ehrlich's ascites cancer. A large amount of malignolipin is needed to establish the structure of this compound, and to reveal its biological and, especially, pathophysiological significance. The method previously described was not suitable for extracting malignolipin in large quantities and, recently, Kosaki and his colleagues have described how the substance can be produced in considerably increased quantities (*Mie Med. J.*, 10, No. 2; August 1960). The investigation makes clear that malignolipin is a phospholipid which has not previously been isolated. Two other articles in the same journal also deal with malignolipin. One indicates a method for detecting and measuring the substance in various tissues including blood and ascites and the other describes the column chromatographic isolation of malignolipin.

Trapping of Plasma by Red Cells

AN accurate method for dividing red-blood cell columns has been devised by Peggy Clark and B. J. Walsh of the New South Wales Red Cross Blood Transfusion Service, Sydney (*Austral. J. Exp. Biol. and Med. Sci.*, 38, Part 6; Dec. 1960). Blood is placed in polyvinyl chloride tubing which is sealed at one end with a glass bead. This tubing is inserted into a piece of glass tube before centrifugation, and later the contents can be frozen before the tubing is divided. The method was used to measure the amount of plasma trapped with the red blood cells. From these measurements the ratio of the true to the observed hæmatocrit value was found to be 0·94 at centrifugal forces greater than 1,430*g*. The ratio decreased with decreasing relative centrifugal force, but variations in the hæmatocrit value did not alter the correction factor. The amount of plasma trapped in the centrifuged and sedimented normal human blood decreased from top to bottom of the red-cell columns, but the amount in different sections of the columns became uniform as the time of centrifugation or of sedimentation increased. A blood sample with a high sedimentation-rate showed a different pattern on sedimentation.

Leverhulme Research Awards

THE following fellowships and research grants tenable for periods up to two years have been announced: *Fellowships*, Dr. A. M. Dunn, lecturer in veterinary parasitology, University of Glasgow, for work on the parasitic helminth fauna of wild ruminants in Britain; P. Haggett, University demonstrator in geography, University of Cambridge, for work on secular changes in the forested area of the Serra do Mar, Brazil, 1814–1962; Dr. R. P. A. Sneeden, lecturer in chemistry, University of Glasgow, for investigations on the structures of large-ring antibiotics; Dr. L. E. Sutton, demonstrator in physical chemistry, University of Oxford, for studies on the significance of molecular shapes and sizes. *Research grants*, N. S. Angus, chief metallurgist, the Production Engineering Research Association, Melton Mowbray, for a metallurgical and chemical examination of samples of early iron and steel; E. G. Bowen, professor of geography and anthropology, University of Wales, Aberystwyth, for studies on the historical geography of the early Christian period in Celtic Europe; J. Heath, of the Nature Conservancy, Grange-over-Sands, for taxonomic and biological studies of the Micropterygidae and Eriocraniidae;

R. F. Jessup, official of the Midland Bank, Ltd., for a survey of Roman barrows in Britain and northern Europe; M. Kaufman, senior lecturer in plastics technology, National College of Rubber Technology, for his studies on the history and development of the plastics industry; W. A. Sands, senior scientific officer, H.M. Overseas Civil Service (Research Branch), for a revision of the termite subfamily Nasutitermitinae from the Ethiopian zoogeographical region; Dr. E. C. Southward, independent research worker, Marine Biological Association, Plymouth, for studies on the biology of *Pogonophora*.

Fishery Research Training Grants

The Ministry of Agriculture, Fisheries and Food and the Department of Agriculture and Fisheries for Scotland are offering a number of one-year postgraduate training grants in fishery research tenable from October 1. These grants are intended to enable selected candidates to undergo a specified course of training to fit them for the investigation of problems in marine or freshwater science. Applications will be considered from candidates for permission to register for a higher degree in circumstances where this seems likely to be consistent with the requirements of the approved fishery research training programme. The number of training grants to be awarded during 1961 will probably not exceed three. Both men and women are eligible to apply. Candidates must be British subjects and graduates with honours in science of a university or possess equivalent qualifications. The value of the training grant will depend on the centre at which training is undertaken, and on whether the student is able to live at home, but will not normally be less than £270 nor exceed £420 per annum. For candidates with two years postgraduate experience, however, a grant of up to £470 per annum may be awarded. Further information can be obtained from the Secretary, Development Commission, 3 Dean's Yard, Westminster, London, S.W.1.

The Association of Applied Biologists

The following honorary officers were elected for 1961–62 at the recent annual general meeting: *President*, Dr. P. W. Brian; *Vice-President*, Dr. M. A. Watson; *President-Elect*, Prof. H. G. H. Kearns; *Treasurer*, Dr. F. Raw; *General Secretary*, Dr. L. Broadbent; *Programme Secretary*, M. J. Way; *Editor*, R. W. Marsh; *Assistant Editor*, Dr. I. Thomas. New members of Council elected were: Dr. F. T. Last, F. G. H. Lupton, Dr. D. Rudd Jones and D. W. Wright.

American Society for Engineering Education

The following have been elected officers of the American Society for Engineering Education: *President*, Dr. Robert W. Van Houten, president of the Newark College of Engineering and director of the Newark Technical School; *Vice-Presidents*, Dr. George A. Marston, dean of Engineering at the University of Massachusetts, and Dr. Curtis L. Wilson, Dean of the Missouri School of Mines and Metallurgy; *Treasurer*, Wendel W. Burton, of the Minnesota Mining and Manufacturing Co.

The International Society for Research on the Reticuloendothelial System

The following have been elected officers and council members of the International Society for Research on the Reticuloendothelial System: *President*, Dr. Albert S. Gordon (United States); *Vice-President (Europe)*, Dr. Bernard N. Halpern (France); *Vice-President (Western Hemisphere)*, Dr. Ignacio Gonzalez-Guzman (Mexico); *Vice-President (Asia)*, Dr. Kaneyoshi Akazaki (Japan); *Secretary-Treasurer*, Dr. John H. Heller (United States); *Council*, Dr. Shigeyasu Amano (Japan), Dr. Baruj Benacerraf (United States), Dr. Charles A. Doan (United States), Dr. Thomas F. Dougherty (United States), Dr. Tede Eston (Brazil), Dr. John F. Loutit (United Kingdom), Dr. Alberto M. Marmont (Italy), Dr. A. Ashley Miles (United Kingdom), Dr. John W. Rebuck (United States), Dr. Jorge Da Silva Horta (Portugal), Dr. Bo Thorell (Sweden), and Dr. Guy Voisin (France).

The International Union of Crystallography

The International Union of Crystallography has announced three forthcoming symposia: a symposium on "Electron and Neutron Diffraction", to be held at Kyoto, Japan, during September 25–30 (further information can be obtained from Prof. S. Miyake, Science Council of Japan, Ueno Park, Tokyo); a symposium in commemoration of the fiftieth anniversary of the discovery by Prof. Max von Laue of the diffraction of X-rays by crystals, to be held at Munich during July 25–28, 1962 (further information can be obtained from Prof. F. Bopp, Institut für Theoretische Physik der Universität, Geschw. Scholl-Platz 1, Munich 22); sixth general assembly and international congress of the Union, to be held in Rome during September 9–18, 1963 (further information can be obtained from Dr. W. H. Taylor, Crystallographic Laboratory, Cavendish Laboratory, Cambridge).

Rutherford Jubilee International Conference

A conference is to be sponsored by the International Union of Pure and Applied Physics, the Royal Society, the Institute of Physics and the Physical Society, and the University of Manchester, to commemorate the discoveries of Rutherford at Manchester, and in particular the fiftieth anniversary of the Rutherford scattering law. The conference will be held at the Physics Department, University of Manchester, during September 4–8. The programme has been divided into nine sessions: *September* 4 (1) high-energy investigations of nuclei (morning), (2) collective motion in nuclei (afternoon): *September* 5 (3) the nuclear ground-state (morning), (4) Rutherford at Manchester (afternoon); *September* 7 (5 and 6) direct interactions (morning and afternoon); *September* 8 (7) weak interactions (morning), (8) open session (afternoon), (9) conference summary. Further information can be obtained from Dr. L. J. B. Goldfarb, Rutherford Jubilee International Conference, Physics Department, The University, Manchester, England.

University News: Belfast

Dr. R. Common has been appointed to a lectureship in geography, and Mr. M. Cohen has been appointed to a lectureship in applied mathematics.

Birmingham

Dr. W. F. Vinen, university demonstrator in physics, University of Cambridge, has been appointed to a vacant established chair of physics within the Department of Physics from October 1, 1961. The title of professor of taxonomic botany has been conferred on Dr. J. G. Hawkes, at present senior lecturer in taxonomy in the Department of Botany, from May 1, 1961.

The following appointments have also been announced. *Senior lectureships*: Dr. G. V. Chester (mathematical physics); Dr. A. S. Jones (chemistry); Dr. L. W. Poel (botany); Dr. J. W. Railly (mechanical engineering); Mr. J. G. Henderson (electrical engineering); Sir Francis Knowles (anatomy); Mr. A. A. Walters (econometrics and social statistics); Dr. W. E. Cavenagh (social study). *Lectureships*: Dr. D. E. Cohen (pure mathematics); Mr. H. P. Rogosinski (pure mathematics); Dr. R. H. Jones (civil engineering); Dr. M. H. Jeynes (bacteriology); W. R. H. Batty (chemistry); Dr. J. P. Simons (chemistry); Prof. E. N. Corlett (engineering production); Dr. A. J. Miller (highway and traffic engineering); T. Brereton (mining and minerals engineering); J. R. Rawling (mining and minerals engineering). *Research fellowships*: Dr. J. Lehmann, to be Imperial Chemical Industries Research Fellow in the Department of Chemistry; P. Johnson, in the Department of Medical Biochemistry and Pharmacology; R. Joy, in the Department of Medical Biochemistry and Pharmacology; Dr. B. Sakita, in the Department of Mathematical Physics.

The University has received and accepted during the period December 22, 1960–April 12 gifts and grants totalling £271,113 for research purposes. Included in this figure are: a grant of £157,143 from the Ford Foundation to support a long-term programme of research in the Department of Anatomy into the reproductive physiology of monkeys; a grant of £42,300 over five years from the Department of Scientific and Industrial Research for research on organic fluorine compounds in the Department of Chemistry.

Edinburgh

The following appointments were recently announced: *Senior Lecturers*, Dr. E. A. Smith (public health and social medicine), Dr. Allan Campbell (zoology); *Lecturers*, G. O. Goudie (engineering), Dr. Tao-Ching Hsu (engineering), A. L. Florence (engineering).

Glasgow

Dr. C. H. Wilson, vice-chancellor of the University of Leicester, has been appointed principal of the University of Glasgow, in succession to Sir Hector Hetherington, who retires on September 30.

London

Dr. W. B. Whalley, reader in organic chemistry in the University of Liverpool, has been appointed to the University chair of chemistry tenable at the School of Pharmacy.

Dr. I. C. Percival has been appointed to the University readership in applied mathematics tenable at Queen Mary College, and Dr. S. J. Pirt, principal scientific officer at the Microbiological Research Establishment, Porton, has been appointed to the University readership in microbiology tenable at Queen Elizabeth College.

Dr. P. Armitage, a member of the Statistical Research Unit of the Medical Research Council at the London School of Hygiene and Tropical Medicine, has been appointed to the University chair of medical statistics tenable at that school. Dr. Dennis Lacy, lecturer at St. Bartholomew's Hospital Medical College, has been appointed to the readership in zoology and comparative anatomy tenable at that college.

Dr. J. A. W. Dalziel of the Imperial College of Science and Technology has been appointed reader in inorganic and analytical chemistry in the Chelsea College of Science and Technology. Dr. J. D. Donaldson of the University of Aberdeen has also been appointed as a lecturer in the Department of Chemistry of the College.

Manchester

Dr. F. J. Ursell, at present lecturer in mathematics at the University of Cambridge, has been appointed Beyer professor of applied mathematics in succession to Prof. M. J. Lighthill on a date to be arranged.

Announcements

Sir John Cockcroft, master-designate of Churchill College, Cambridge, has been appointed chancellor of the Australian National University, Canberra, in succession to Lord Bruce; this appointment will not affect Sir John's position at Cambridge.

Prof. J. R. Partington has been given the Dexter Award of the American Chemical Society for his work in the history of chemistry. Prof. Partington is emeritus professor of chemistry in the University of London, but for some years has been resident in Cambridge. The Dexter Award consists of a money prize and a plaque, and it is expected that the Award will be made at a meeting of the Chemical Society in the autumn by Dr. Edelstein, president of the Dexter Chemical Corporation of New York.

Dr. G. Malcolm Dyson of Loughborough, Leicester, has been given the Austin M. Patterson Award of the American Chemical Society for his work on the storage and retrieval of scientific data by computer techniques. The award is made every two years in honour of the late Dr. Austin M. Patterson in recognition of contributions in the field of chemical literature and especially in the documentation of chemistry. This is the first time that the award has been made to a non-American.

Dr. E. Eastwood, chief of research of Marconi's Wireless Telegraph Co., Ltd., Chelmsford, Essex, has been appointed director of research responsible to the managing director for the Company's research policy.

Prof. George Temple, professor of natural philosophy, University of Oxford, has been appointed chairman of the Aeronautical Research Council, in succession to the late Prof. W. J. Duncan.

The thirteenth British Electrical Power Convention of the Electrical Development Association is to be held at the Winter Garden, Eastbourne, during June 12–15. The theme of the Convention will be "Electricity in the Prosperity and Welfare of the Nation". Further information can be obtained from J. I. Bernard, Electrical Development Association, 2 Savoy Hill, London, W.C.2.

A summer school in health physics (radiation protection) arranged by Dr. Hugh D. Evans, lecturer in radiation hazards and health physics, will be held in the Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, during July 3–14. Further information can be obtained from Dr. H. D. Evans, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7.

THE SECOND U.K. *SCOUT* SATELLITE

THE British National Committee on Space Research, the U.K. Steering Group on Space Research and the U.S. National Aeronautics and Space Administration have agreed on the scientific instrument payload for the second U.K. *Scout* satellite to be launched by the U.S. National Aeronautics and Space Administration. The scientific instruments, as in the first British *Scout* satellite, will be designed and provided by British scientists.

The experiments are designed to measure radio emissions from the Galaxy at wave-lengths too long to penetrate the Earth's atmosphere; to measure the vertical distribution of ozone in the regions of the atmosphere in which it is being formed; and to measure the number and size of fine dust particles encountered by the satellite. In addition, the galactic radio equipment is designed to gain information on the electrical condition of the high atmosphere.

It is expected that the satellite will be launched in about two years time. The orbit will probably pass over the United Kingdom and the United States, and it should be possible to receive radio information both in these countries and at stations in the British Commonwealth.

As for the first British *Scout* satellite, this one will be launched by a four-stage rocket system using solid propellants. It is expected that the satellite orbit will range between 300 and 2,000 km. from the Earth. The instrumentation is being so arranged that the satellite will supply information on Galactic noise, atmospheric ozone and micrometeorite flux.

Galactic Noise

A project to measure the galactic noise in the frequency-range 0·75–3 Mc./s., and the exploration of the upper ionosphere, is to be carried out by Dr. F. Graham Smith, Mullard Radio Astronomy Observatory, Cavendish Laboratory, University of Cambridge.

Dr. Smith will have three objectives in mind: (*a*) to measure the intensity of the galactic background at as low a frequency as possible under known conditions of receiver sensitivity and under known conditions of ionospheric effects on propagation and aerial impedance; (*b*) to watch for temporal or spatial variations of galactic radiation; (*c*) to explore the electron density in the upper *F* region.

Atmospheric Ozone

Measurement of atmospheric ozone is under the direction of Dr. R. Frith and Dr. K. H. Stewart (Air Ministry, Meteorological Office, London). This will be carried out by two methods: (*a*) a spectrum scanning method; (*b*) a method in which a broad band of the spectrum is observed.

Dr. Frith's experiment will have as its main objective the measurement of the vertical distribution of ozone in the Earth's atmosphere as often and in as many places as possible. These measurements should add to our knowledge of the processes forming and destroying ozone, of the air motions which distribute it and of the effects of ozone on the thermal equilibrium of the upper atmosphere. Measurements will be made of the intensity of the radiation received from the Sun at selected wave-lengths in the ozone absorption region in the ultra-violet at times when the satellite is entering or leaving the Earth's shadow and the solar rays have to pass through the Earth's atmosphere to reach the satellite.

Micrometeorite Flux

The measurement of the micrometeorite flux is is being organized by Dr. R. C. Jennison (Nuffield Radio Astronomy Laboratories, University of Manchester, Jodrell Bank, Cheshire).

Dr. Jennison's experiment has as its objective the detection and measurement of micrometeorites encountered by the satellite. He will use a technique in which the holes formed in a thin metallic film by the impact of micrometeorites will be detected by an optical method. Sunlight passing through the holes will fall on a photosensitive strip of solar cells and give a signal from each hole in turn from which the number and size of the holes, and hence of the micrometeorites, can be deduced. The sensitivity is such that the holes formed by the particles, 1μ in diameter or greater, may be detected.

THE BRITISH AGRICULTURAL HISTORY SOCIETY

THE annual conference of the British Agricultural History Society was held during April 5–7 at Seale Hayne Agricultural College. On the first evening members heard papers from Mr. Peter Holmes, the County agricultural officer, and Dr. W. G. Hoskins, of Oxford. Mr. Holmes described the farming regions of Devon and did his best to disabuse his audience of the idea that Devonshire was entirely composed of the good red soils associated with the 'Glorious Devon' of the travel posters. He emphasized the importance of the hill-farming economy and explained also that there were large areas of indifferent shale soil in the north and north-east which were difficult to farm and not immensely productive.

Dr. Hoskins has recently been engaged in a study of the types of farmhouse on Dartmoor and made an appeal for more field work in the area for, as he said, "The history of the moor is as yet largely unwritten". He outlined briefly what is known of the earlier settlement of the moor and discussed its recolonization at the end of the Middle Ages. There are, he explained, still to be found many sixteenth- and seventeenth-century 'long houses' or buildings of the type that had both human dwelling and cattle stalls under one roof with a common doorway and central dividing passage.

The following day Dr. Hoskins led an excursion over the moor and showed the conference examples of this type of house. The party also visited a deserted village site below Hounds Tor which has recently been discovered by members of the Ordnance Survey. About twelve house sites, thought to be identified with seven or eight farms, are clearly visible from the rubble remains, but nothing is yet known of the date of settlement or of desertion; excavation on the site will start this summer.

On the second evening of the conference members heard a paper from Prof. Slicher van Bath, head of the Department of Rural History at Wageningen in the Netherlands. Prof. Slicher van Bath discussed the use of farm accounts as material for investigating farm management and agricultural output between the Middle Ages and the eighteenth century. He outlined the results of a study he had made of extant accounts in several countries, including those of the English early seventeenth-century farmer, Robert Loder of Harwell (Camden Third Series, **53**, 1936).

On the last morning of the conference there were papers from Mr. J. Z. Titow of Cambridge and Prof. Beresford of Leeds. Mr. Titow discussed his recent work on the types of manors to be found on the Winchester estates in the thirteenth century. It had, he said, been assumed that the descent of villein property was mainly from father to son, but he produced substantial evidence to support a plea for considering more seriously the position of widows. On many of the Winchester manors it was clear that holdings were often left to the widow and that a kind of 'widow cycle of inheritance' was thus set up. A young man in search of a holding would therefore seek a widow with one. As a result of this a widow might remarry and leave the holding on her death to her second husband who in his turn remarried, leaving it on his death to his widow who might then marry again; direct descent to the eldest son appeared to be relatively uncommon.

Prof. Beresford set out some provisional ideas on the development of the unusual settlement pattern in fourteenth-century Cornwall. He explained that a great deal more work was required on Cornish settlement patterns, and that potential workers would be encouraged to know that from the material in the Duchy of Cornwall archives it was possible to trace the occupation of Duchy holdings from the fourteenth century to the early nineteenth. Dr. Hoskins, in his concluding remarks as chairman for Prof. Beresford, said he hoped members, as a result of the conference, would be more conscious of the need for work in south-west England and the rich material that awaited them. He was glad, too, that the Society had met in the highland zone, for, in his opinion, the British highlands had been neglected by agrarian historians.

J. W. Y. HIGGS

DISEASE TRANSMISSION BY TICKS

THE papers presented at the recent sixth symposium of the Zoological Society of London on "Some Aspects of Disease Transmission by Ticks", held in London on March 8, revealed how some of the pieces of this complex jig-saw puzzle are gradually being filled in, but at the same time it was indicated that there are major deficiencies in our knowledge. Dr. J. MacLeod, by reference to a very interesting mechanical analogue of the forces at work, showed that the disease associations of ticks represent meshes in the food web of a biotic community which includes the pathogens, their tick vectors, the vertebrate hosts and the vegetational environment which supports and/or shelters them all. In this connexion it is worth noting that the physical relationships of tick distribution in Britain to the type of ground-cover are known for only one of the nineteen species of ticks; the biotic relationships, with two exceptions, are practically unknown. So far as British ticks are concerned, *Ixodes ricinus* has been the species most thoroughly investigated, principally because of its known disease relations. One of these diseases, Scottish louping ill, like other viruses of tick encephalitides, appears to have a casual rather than an intimate association with its hosts, which are principally sheep in Britain. Although the ease with which this disease can be transmitted by non-British ticks, for example, *Rhipicephalus appendiculatus*, suggests that any of the mammal-infesting British ticks would be capable of transmitting it to any British mammal; the infection has been demonstrated in *I. ricinus* from sheep in Nature, both by inoculation and infection.

Clinically, louping ill resembles poliomyelitis of man, and the virus multiplies primarily outside the central nervous system and during the fever, which precedes clinical signs, the pathogenic micro-organism can be detected in the blood. Dr. W. S. Gordon's experimental results indicate that most sheep on a louping ill farm eventually become infected. Many develop only a fever, recover and are afterwards immune, but a small proportion develop clinical signs of infection of the central nervous system. In these cases lesions of an encephalomyelitis can be demonstrated and virus recovered from the brain and the spinal cord. On a world scale, according to Dr. C. E. Gordon Smith, there are thirteen known tick-borne animal viruses transmitted by five genera of hard ticks and one of soft ticks. All these viruses, except one, cause disease in man or domestic animals which are usually incidental hosts of the viruses. Their long-term natural maintenance depends on the geographical and behavioural association between vector tick and ground-frequenting mammal, and bird species, in the blood streams of which the virus inoculated by tick-bite can circulate adequately to infect further ticks. Because tick populations are adequate only where suitable vegetation provides the appropriate microclimate, infections occur in restricted foci. Wild vertebrates do not usually show the disease, but can be infected and circulate virus only once because of antibody formation, and accordingly their population turnovers must supply enough new susceptibles annually. Movement of these viruses to new areas probably depends on the carriage of infected ticks by large mammals or migrant birds. A stable enzootic disease changes to epizootic or epidemic mainly because of population-changes in ticks or vertebrates, or introductions by man of domestic animals or introduction of virus to new areas.

A second febrile disease of sheep and cattle in Britain is tick-borne fever, which was discovered during the investigation of louping ill by Gordon *et al.* Hitherto tick-borne fever has been classified as a *Rickettsia*, but Dr. A. Foggie indicated that apart from the presence of an arthropod vector it has little in common with the true rickettsiae, such as those causing typhus and Rocky Mountain spotted fever. The forms seen in parasitized phagocytes have some resemblance to large viruses, and, under the phase-contrast microscope, the elementary bodies in morulæ have been seen in rapid Brownian movement, a phenomenon paralleled in colonies of psittacosis virus. While the organism had been provisionally named *Rickettsia phagocytophilia*, Dr. Foggie was of the opinion that it should now be included in the genus *Cytoecetes*, in so far as it morphologically resembles the type species *C. microti*, a tick-borne parasite of the polymorphs of voles in Massachusetts. Tick-borne fever is widespread, and an important point, made by Dr. MacLeod, was that in relation to 'inefficient' links in the biocœnose through self de-ticking, as in birds and some carnivores, transmission can occur by the second day after attachment of nymphs. Sheep are a reservoir of infection for ticks for at least several weeks after subsidence of the reaction. Cattle and goats are susceptible, and cross-infectivity and cross-immunity tests by Dr. Foggie suggest that there may be specific differences between the bovine and ovine strains of the organism; a recently isolated strain from red deer was of similar infectivity to the sheep strain. The harmful effects of louping ill are aggravated by the presence of the tick-borne fever microorganism, as shown by Dr. Gordon's experiments in exposing susceptible sheep to natural infection with louping ill and tick-borne fever.

In the wider field of rickettsial infections and ticks, Prof. D. S. Bertram outlined the characteristics of rickettsial organisms as deduced by various workers from studies, including some by electron microscopy, on species of *Rickettsia* pathogenic to man. The significance of ticks in human tick-borne rickettsiosis was considered as well as comments on tick-borne *Rickettsia*-like organisms of veterinary interest. Prof. Bertram then illustrated that differentiation within the controversial assemblage of pathogenic and symbiotic organisms may benefit from electron microscopy, and that this technique presents an opportunity for fruitful re-examination of the fate of the different rickettsiae in their tick hosts.

Although tick pyæmia is constantly associated with an infestation of *Ixodes ricinus*, the tick does not appear to be a vector of the causal *Staphylococcus*. Dr. Foggie's observations show that *Staphylococci* of the same bacteriophage types as those found in tick pyæmia cases were found to be common commensals on the skin of lambs in both tick-free and tick-infested areas. Lambs in the neutropænic phase of tick-borne fever were shown to be a hundred-fold more susceptible to the intravenous inoculation of *Staphylococci* than healthy lambs. The subcutaneous or intradermal inoculation of *Staphylococci*, either with or without an extract of tick salivary gland, or the feeding of ticks on heavily contaminated skin areas, failed to reproduce the disease in both normal and neutropænic lambs.

Piroplasmosis (redwater fever) in cattle in Britain is due to a piroplasm now believed to be distinct from *Babesia bovis*, and for which resuscitation of the earlier name of *B. divergens* is proposed. Dr. H. E. Shortt made the point that piroplasmosis is one of the major causes of morbidity and mortality in cattle, and as such has a serious effect in limiting the potential food supplies of man. So far as is known, ticks are the chief and very likely the only vector of this condition, and, although Africa is probably the most seriously affected continent, all parts of the world harbour both piroplasms and their tick-vectors. Our knowledge of the life-history of the piroplasms in the tick is still inadequate and Dr. Shortt, in describing the life-cycle of *Babesia canis* in *Rhipicephalus*, has made notable contributions to filling in many of the blanks. The possibility of the introduction into Britain of equine and canine piroplasmosis, transmitted by *Dermacentor reticulatus* on the continent, was made by Dr. MacLeod. The suggested occurrence of *B. caballi* in Britain cannot be ignored, and with the apparent establishment of *D. reticulatus* in south-west England, due probably to similar ecological requirements to those of *I. ricinus*, the wild and free-range ponies of Devon and Cornwall, and in the New Forest, may well be ecologically susceptible to devastation by one or both of these disease agents if they were introduced. Their susceptibility is more probable from the apparent catholicity of the vector-range of these piroplasms, as the latter have been transmitted experimentally by several tick species.

Man is normally insusceptible to infection, but as ticks are almost as ubiquitous as mosquitoes and in infested regions man is constantly exposed to their bites, the possibility of the tick acting as a reservoir of occult or inapparent parasites of man cannot be ignored. Prof. P. C. C. Garnham stated in this connexion that the removal of the spleen in man abolishes immunity and the occult parasites multiply and a fatal infection may ensue. The point was made that thousands, if not millions, of people living under rural conditions, and in contact with pastures, may harbour inapparent infections of *Babesia*, other piroplasms, or even certain tick-borne viruses. Whether such a condition is harmless, even in people possessing a spleen, is a subject being investigated further by Prof. Garnham.

Relapsing fever, a tropical disease associated with soft ticks, is transmitted by the bite and/or contamination of the bite wound by the coxal fluid which is produced by some species during feeding. Dr. G. A. Walton, in discussing human relapsing fever epidemiology in Eastern Africa, described the morphological, biological and distributional peculiarities of four species of Argasid ticks previously included under the name *Ornithodoros moubata* (Murray, 1877). The part played by each of them in the transmission of human relapsing fever was outlined with reference to the evolution of the East African domestic subspecies, and the decisive effect on local transmission of *Borrelia duttoni* by the feeding preferences of its races on one hand and the distribution and social behaviour of the native human races on the other. The existence and implications of immunity to the infection in man were illustrated in relation to minor and major human population movements and to other factors producing changes in the territorial incidence of the disease. Dr. M. G. R. Varma directed attention to the fact that, in an infected tick, spirochætes may be found in practically every organ; but the organs are not necessarily infected with the same frequency or to the same degree. Moreover, two species of spirochætes may behave differently towards the same tick organ. Both the frequency and the degree of infection are connected with the method of transmission of spirochætes. Thus it has been shown that the salivary glands of nymphs of *Ornithodoros moubata* are more heavily infected with *Borrelia duttoni* than are those of adults. There is also some evidence to show that infection of the salivary glands may die out in the course of time, so that old adults, apparently as a result of repeated feeds, rarely transmit the infection by bite.

Infection of the coxal glands in those species of ticks which do not produce any coxal fluid while feeding can have no importance in the transmission of spirochætes and such ticks transmit solely by the bite. Coxal fluid from such ticks has been shown to be non-infective although the glands themselves may be infected.

Continued experimental passage of the spirochætes through the vertebrate hosts may result in their failure to infect ticks successfully. However, by inoculating spirochætes directly into the hæmocœle, they are able to infiltrate the salivary glands and coxal glands and transmit the infection, suggesting that the gut may act as a partial barrier to the entry of spirochætes into the hæmocœle.

Some knowledge of the nature of the food imbibed by ticks and the methods of acquiring it may be of significance in assessing the timing of the intake and introduction of blood pathogens from and to the host. Examination of sections of larval and nymphal ticks feeding on rat skin by Miss Evelyn Sutton and Dr. D. R. Arthur shows evidence that a process involving the intake and digestion of non-blood tissue occurs. Moreover, field observations of adult *Ixodes ricinus* feeding on cattle revealed that ticks of the same degree of engorgement range in colour from light yellow to greyish, especially in the earlier stages. These colour differences are a reflexion of the colour of the gut contents visible through the integument, and, as afterwards confirmed by spectrophotometric analysis, the darker coloured gut contains a high proportion of blood and the lighter coloured gut a predominance of non-blood fluids. The ingestion of blood-inhabiting pathogens by the tick may accordingly be delayed for some days and in some cases may not occur at all. In certain larvæ, particularly those with short penetrant ability, it may well be that the diet is exclusively one of non-blood digested tissues, in which event the ingestion and passage of blood-inhabiting pathogens are negligible.

One of the significant features in ticks and mites is the ability of their pathogens to pass transovarially from one generation to the next. Prof. Bertram discussed how this may happen in rickettsiae, Dr. Varma showed how it occurred in ticks infected with *Borrelia duttoni* and Col. Shortt mentioned the passage of *B. canis* through the ovum of *Rhipicephalus*. Transovarian transmission in ticks and mites may be either obligatory or incidental. Prof. Garnham stated that obligate transovarial transmission occurs in *Karyolysus* and in *Rickettsia tsutsumagushi*, whereas *B. canis* for example, as Shortt described, may either progress from adult to egg to larva (that is, transovarial) or from stage to stage. Viruses sometimes pass through the egg, and spirochætes often are transmitted in this way, although the organism tends to become less virulent to the vertebrate host after such passage, and, if this is repeated for several generations, the progeny is eventually freed of infection. It has been suggested that ease of transovarial transmission in ticks may be related to the fact that only a single membrane separates the egg from the hæmocœle, whereas in insects greater insulation against the entry of viruses and pathogens is afforded by the presence of three membranes.

The proceedings of the symposium will be published in full by the Zoological Society of London.

D. R. ARTHUR

QUEEN ELIZABETH COLLEGE, LONDON

SIR JOHN ATKINS LABORATORIES

QUEEN ELIZABETH COLLEGE (University of London) was again honoured by a visit from H.M. Queen Elizabeth, the Queen Mother, Chancellor of the University of London, when, on May 9, she opened the new building on Campden Hill, the Sir John Atkins Laboratories. Her Majesty addressed members of the College and distinguished guests assembled outside the Laboratories, and then made a tour of the building, where she talked to a number of the staff and students who work there.

The building, designed by Messrs. Adams, Holden and Pearson, and erected by Messrs. Holland and Hannen and Cubitts (G.B.), Ltd., is six storeys of brown Buckinghamshire facing bricks, with panels of cream bricks between the lines of windows, and reconstructed Portland stone dressings. It houses the Departments of Biology, Microbiology, and Nutrition, which moved from the main College building last autumn, and released much-needed space there for the expansion of other departments. On part of the top floor there is a self-contained Isotope Unit for the use of any department needing to work with radioactive materials.

The Nutrition Department was founded in 1954, following the establishment by the University of London of the degree of B.Sc. (Nutrition), still the only degree of its kind in the world. For the first six years it worked in very restricted quarters, in part of two prefabricated huts. Now it has an area of more than 12,000 sq. ft., and is the first university department in Britain to have been specially designed for teaching of and research in nutrition. In addition to a large laboratory for forty-two undergraduates and a smaller teaching laboratory for twelve advanced students, there is accommodation for twenty-two research workers, with ten animal rooms for the rats and mice used in studying nutritional problems. Already, with the aid of grants from the research councils, from research foundations and from various industrial organizations, it has been possible to add eight graduate research workers to the staff of the Department. From this beginning the College will go on advancing by research the science of nutrition, a science which has assumed a new importance in face of the imminent danger of food production and food distribution failing to keep pace with the upsurge of world population; and by training a steadily increasing body of nutritionists, qualified in all the aspects of the subject—scientific, social and economic—which now make up the full study of nutrition, the College will provide the workers needed not only to help in the fight against hunger and malnutrition, but also to deal with the different nutritional problems of the well-fed countries.

The Department of Microbiology, already known for its research, but hitherto greatly hampered by lack of space, now has fully air-conditioned research laboratories and is probably one of the best equipped non-medical microbiology departments in any university in Britain. At present its undergraduate teaching is confined to ancillary courses, but if the University decides to introduce a B.Sc. (Special) degree in microbiology, Queen Elizabeth College will be among the first to provide courses for it. The large teaching laboratory, with about forty student places, is admirably fitted for the purpose. The University has just instituted a readership in microbiology tenable at the College, and from October 1961 the reader will be head of the Department.

The Department of Biology has the whole of the ground and first floors and part of the lower ground floor of the new building for zoological and botanical teaching and research. In its old premises it had little room for research workers. Now it has accommodation for twenty, including the teaching staff, and already six postgraduate research workers have been added to the Department, including one post-doctoral Research Fellow. The two teaching laboratories each have sixty places for undergraduates, and the College, which already had one of the biggest entries in the University for the B.Sc. (General) degree, hopes to be able to increase the number still further. Britain needs specialists, but it also needs many scientists with a broad and balanced education for industry, for teaching, and for many other important walks of life. This need is well filled by graduates with a London B.Sc. (General) degree, and the College aims at seeing that this degree is accorded the importance it deserves.

It is most fitting that this new building should be named after Sir John Atkins, the first Fellow of the College. Sir John was largely responsible for the foundation of the College. As a young doctor he felt so strongly the need for a college where domestic subjects could be taught with a proper scientific background that in 1911, by his own efforts, he raised the necessary funds for the erection of the main buildings in Campden Hill Road. He joined the Governing Body in 1912 and still serves on it. Through all these years he has watched over the interests of the College, and cherished its aims. For thirty-six years, as chairman of the Council, he guided it through the most crucial stages of its development. The Sir John Atkins Laboratories will be a permanent reminder of all that past, present and future generations of students owe to him.

DAMAGE BY *RHIZINA UNDULATA* IN CONIFEROUS PLANTATIONS

THOSE who attempt to establish, or re-establish, forests artificially on land on which there was never any natural forest, or from which every remnant of a natural forest soil has long since disappeared, are always liable to encounter fresh trouble. This fact is brought home forcibly in a recent publication by the Forestry Commission which is concerned with a fungous disease which, significantly, has been observed to be serious mainly in plantations recently established on non-forest soils*.

The title, *Group Dying of Conifers*, is unfortunate. Groups of trees may die for a variety of reasons as, for example, from strikes by lightning, from deposition of toxic materials, like manure heaps, within the stand, from attacks by fungi other than *Rhizina*, and so on, and why this forest record is not simply entitled *Rhizina undulata* with an appropriate equivalent in English is misleading and difficult to understand. A suitable name would appear to be the 'fire-site fungus'.

Rhizina undulata Fr. ex Fr. is described as 'colonizing' the sites of fires lit during forestry operations in pole-sized stands. From these sites it spreads outwards over a limited period of years, with the result that groups of dead trees occur within the stand. In some cases these breaks in the canopy give access to strong winds and form starting points of what may develop into serious windthrow. *Rhizina* has been recognized as a parasite since 1894, and has been described from both eastern and western States in the United States as well as from Europe. Significantly, it does not appear to attack leaf-tree species, only conifers. The first record of so-called 'group-dying' in Great Britain seems to have been in 1936, but it is only since 1953 that *Rhizina* has been frequently observed associated with groups of dead trees in the British Isles.

Messrs. Murray and Young, on the basis of a study of dead groups of trees in 58 forests or estates in Britain, 50 of which are situated along the western seaboard, have clearly confirmed that the fungus becomes recognizable on fire sites, and a very large proportion of the dead groups were associated with fires. This has led to the prohibition of all fires, even those lit for the brewing of tea, in or near the plantations of the Forestry Commission. This means of control can be strongly recommended to other forest owners, although it is often difficult to overcome the passion for tidiness which seems normally to be associated with artificial plantations.

The general history of the disease and its behaviour are described together with a more detailed survey of two infested forest areas in Scotland. There is an excellent description of the fungus itself; but in discussing the nature of the attacks and the behaviour of the fungus the authors have obviously been handicapped by inadequate experience of site examination and by the prevailing ignorance of soil organisms, including fungi, and of their relationship to the organic matter in the soil. It is unfortunate that no full description of any of the sites or soils examined is published although it may have been recorded elsewhere. It has been found that Sitka spruce is especially susceptible to attack, and not solely because it happens to occur in no fewer than 38 of the 58 areas examined. A point which is not made clear is whether *Rhizina* exists in the soil before the plantation is established—possibly associated with the organic matter therein—and Sitka spruce is most often planted on soils with a high content of organic matter or on grass- or rush-covered sites. *Rhizina* may exist in close association with grasses, for example, and only when the organic matter is altered or consumed by fire does it virulently attack the feeding roots of the trees. What, for example, happens when *Rhizina* encounters the mycorrhizal fungi usually associated with conifers ? There is a great need for more research into the occurrence and behaviour of all the micro-organisms found in the soil, and it is important for foresters that soil research should be based, where possible, on the soil of the natural forest. While the natural forest is a reality which has stood the test of time, the artificial forest still remains an illusory concept nowhere brought to satisfactory permanency, and liable to be seriously disturbed by organisms, like *Rhizina*, beyond the forester's control.

TRENDS IN JUVENILE DELINQUENCY

FOR some years the World Health Organization has taken an interest in the problem of juvenile delinquency. In 1949, at the request of the United Nations, the Organization carried out a study of the psychiatric aspects of the origin, prevention and treatment of juvenile delinquency as a contribution to the United Nations programme for the prevention of crime and treatment of offenders. Since then, representatives of the World Health Organization have taken part in many conferences and have regularly attended meetings of the United Nations Consultative Group on the Prevention of Crime and the Treatment of Offenders; and the Organization has, through its Regional Office for Europe in Copenhagen, organized a seminar on the psychiatric treatment of offenders.

In 1959, again at the request of the United Nations, another study was carried out by a psychiatric consultant, Dr. T. C. N. Gibbens, senior lecturer in forensic psychiatry in the University of London, who was appointed by the World Health Organization to complement the earlier study with a review of present trends in juvenile delinquency, based on his own personal experience, the recent literature and first-hand information obtained during visits to a number of countries—Australia, Denmark, the Federal Republic of Germany, Israel, Lebanon, Poland, Sweden and Yugoslavia. Dr. Gibbens's report, which was submitted to the second United Nations Congress on the Prevention of Crime and Treatment of Offenders, has now been published with some minor amendments*.

The new forms or manifestations of juvenile delinquency consist partly of delinquent acts which are a consequence of new opportunities for crime, but which do not differ in their essential character from more traditional forms, and partly of offences which appear to reveal a fundamental change in behaviour, or the participation of sections of the community which have not previously been involved in crime.

It is with these newer forms that the author is primarily concerned in his review of social changes, changes in family life and in the individual delinquent, special property offences, sexual offences, wayward girls, violent offences, alcoholism and drug addiction, and hooliganism. He also discusses present trends in prevention, paying particular attention to the development of prediction studies designed to identify young children who are in danger of being seriously delinquent in the future, and to the tendency to design preventive programmes in such a way that their results can be scientifically evaluated. A chapter on treatment deals with diagnosis, treatment at liberty and institutional treatment.

SIMIAN MALARIA

A RECENT issue of the *World Health Organization Chronicle* is concerned with the transmission of malaria parasites between monkey and man*.

The knowledge that such a transmission can take place dates back to 1932, when, in India, Knowles and Das Gupta found that *Plasmodium knowlesi* could cause a febrile infection in man. Knowledge of simian malaria in relation to man was extended in 1948, when *P. rodheini* of African chimpanzees was found to be morphologically and immunologically identical with *P. malariae* of man. Subsequent work showed that human malaria parasites such as *P. vivax*, *P. falciparum* and *P. ovale* could be transmitted to chimpanzees through anopheline mosquitoes although patent parasitæmia appeared only in splenectomized apes.

In certain parts of West Africa the chimpanzee is known to harbour *P. malariae*, and man has been shown to be readily susceptible to the strains harboured. The anopheline vector of the *P. malariae* of these chimpanzees has not been identified. In Sarawak certain strains of human parasites of quartan malaria have been observed to have a peculiar morphology which suggested that the parasite might be of simian origin. In the Amazon region of South America, some *P. vivax* infections in man have been held to be derived from simian malaria. *P. simium*, found in howler monkeys of the forests near Santos, has been suspected of being closely related to *P. ovale*.

---

* *World Health Organization Chronicle*, 15, No. 1, January 1961.

In May 1960, came a new development. During research at the U.S. National Institutes of Health, Bethesda, by Eyles, Coatney and Getz on the transmission to rhesus monkeys of *P. cynomolgi bastianelli*, some very large-scale inoculations of sporozoites into monkeys were carried out. Two staff members of the Institutes, neither of whom had had any recent contact with human malaria, were dealing at close quarters with heavily infected mosquitoes; they both developed illness with fever which, after a remittent period, proved to have tertian periodicity. Blood smears, made on new slides and stained with new stain in clean dishes, showed that both had *vivax*-type parasites with enlarged erythrocytes and Schuffner's stippling. Five millilitres of blood from each of the two individuals, injected intravenously into two uninfected rhesus monkeys, produced *cynomolgi*-type infections in 8 days in one monkey and in 10 days in the other. Two human volunteers each received 10 ml. of blood intravenously from one of the individuals; both developed clinical attacks of malaria with *vivax*-type parasites, enlarged erythrocytes, and Schuffner's stippling, but without high parasite densities.

The two individuals in whom the infection was first discovered received chloroquine treatment within 24 hr. of diagnosis. At the time of treatment both showed low levels of parasitæmia. The parasites promptly disappeared with treatment and no relapse occurred.

Another person allowed 30–50 *Anopheles freebornii*, heavily infected with *P. cynomolgi bastianelli*, to feed on him, and experienced headache, malaise and fever eleven and twelve days later. No parasites were found in his blood, but a monkey free of disease, intravenously injected with 10 ml. of his blood, developed an overt infection in 6 days. A fourth person developed a typical malaria paroxysm with *vivax*-type parasites fourteen days after being bitten by 10 *A. freebornii*, heavily infected with *P. cynomolgi bastianelli*.

Cross-immunity studies were undertaken at Bethesda on two monkeys which had recovered spontaneously from infections with *P. cynomolgi bastianelli*. On being re-inoculated with heavy doses of parasites taken from one of the two monkeys which had been infected by intravenous injection of the blood of one of the two accidentally infected staff members, one monkey showed a transient parasitæmia indicating almost complete immunity. The other had an attack of malaria that was shorter and less severe than the usual *bastianelli* attack. These results supported the view that the human infections were due to *P. cynomolgi bastianelli*.

The significance of these infections of human beings lies in the fact that they were transmitted by mosquitoes which had fed on rhesus monkeys. The theoretical possibility of natural infection of man with monkey malaria had already been suspected; but it was the anthropoid ape, not the monkey, which was formerly suspected as being a possible carrier of human malaria. Monkeys are much more numerous and widespread than apes, and live in closer association with man, and at least seven species of anophelines are known to be able to transmit *P. cynomolgi* to rhesus monkeys. Some of these species are exophilic, and therefore unlikely to be affected by residual insecticides; moreover, the host preferences of anopheline vectors for man and for the monkey are often almost the same. Consequently, experimental proof that man can be infected by monkey malaria opens up a new range of possibilities.

EFFECT OF MASS TRANSFER ON THE VELOCITY OF RISE OF BUBBLES IN WATER

By Dr. J. H. LEONARD and Prof. G. HOUGHTON

Department of Chemical Engineering, University of Pittsburgh, Pennsylvania

ALTHOUGH Datta, Napier and Newitt[1] were the first to suggest that "mass transfer (from bubbles) may be accompanied by some retarding effect", no definite conclusions were reached in this respect from their experiments on carbon dioxide bubbles rising in water. In the present measurements both velocities of rise and mass transfer-rates for bubbles could be measured separately over short distances in a column of water. The apparatus used was a modification of that[2] in which soluble bubbles were formed in a cup under mercury and allowed to rise up through a completely closed 'Pyrex' glass column (9 cm. internal diameter, 270 cm. long) filled with water; the change in volume of each bubble was recorded by registering the position of a mercury meniscus in a horizontal capillary side-arm, which provided the only opening to the atmosphere. By stretching a fine platinum wire through the capillary and connecting the wire to a bridge circuit it was possible to record the position of the mercury meniscus and hence the bubble volume on one channel of a high-speed Sanborn oscillograph. Although the principle was used earlier[3,4], these earlier experimenters used high-speed photography to determine the volume of the bubble by photographing the position of the liquid meniscus in the capillary. However, the present apparatus also differs from that of Houghton *et al.*[2] in that the rising bubbles interrupt a series of light beams and photoelectric cells placed at intervals of 47·0 cm. up the column. As the bubble passed each light beam, the change in light intensity was recorded on a second channel of the Sanborn oscillograph. In this way it was possible to determine the average bubble velocity and the average mass transfer-rate separately over each 47·0-cm. section of the column together with the corresponding average bubble diameter over the same section. In certain instances the velocities of rise, obtained by the method described, were also confirmed independently in a separate apparatus by forming the bubbles at jets of various sizes, using a micrometer hypodermic syringe, and then timing them over a 110 cm. length of column, using a stop-watch and starting the measurements at a distance of 20 cm. from the jet (cf. ref. 5).

Figs. 1 and 2 show that mass transfer has a profound effect on the velocity of rise of soluble gases in water for bubbles with equivalent spherical diameters in the range 2–6 mm. Bubbles with diameters greater than 7 mm. have not been included in these figures, since mass transfer was found to have no significant effect on the velocities of rise of bubbles in the diameter range 6–20 mm., presumably because the profile drag and inertial effects present in the larger bubbles were much more important than the surface effects. The mass transfer-rates for the gases in Figs. 1 and 2 are in the following descending order: carbon dioxide > nitrous oxide > ethylene ≃ nitrous oxide – nitrogen mixture (50 mole per cent) > nitrogen. The largest velocities of rise are found for insoluble gases represented in Fig. 1 by the data for nitrogen bubbles rising in water saturated with nitrogen; in this system, the bubbles expand as they rise, because of the reduction in the hydrostatic head. The gas with the largest mass transfer-rate is carbon dioxide, which also demonstrates the lowest velocities of rise. The systems with intermediate mass transfer-rates between insoluble nitrogen and carbon dioxide also show intermediate effects on the velocity of rise. For example, Figs. 1 and 2 show that bubbles formed from a 50–50 mixture of nitrous oxide and nitrogen have velocities of rise half-way between those of pure nitrogen and pure nitrous oxide. In fact, the figures show that the effect of mass transfer is to lower the velocity of rise as the mass transfer-rate increases, so that the velocities of rise are in the following order: nitrogen > nitrous oxide – nitrogen mixture (50 mole per cent) ≃ ethylene > nitrous oxide > carbon dioxide.

It is evident that the lowering of the velocity of rise for soluble bubbles cannot be explained simply on the basis of a change in terminal velocity of rise with diameter, since the velocities of rise of insoluble bubbles decrease with increase in diameter in the range 2–6 mm., whereas, when mass transfer occurs, the velocity either increases or does not change much with diameter. Furthermore, in no case did the diameter change more than 5 per cent of its value over any section of the column.

Another possible explanation might be that as a bubble decreases in size, it should accelerate if the velocity of rise follows the curve for insoluble bubbles. The acceleration would then produce an increase in virtual mass of the bubble (cf. ref. 6), which in turn would reduce the buoyancy forces and indirectly affect the velocity of rise. However, the experiments using pure nitrous oxide bubbles in aqueous nitric acid (*p*H 0·7) shown in Fig. 2 tend to eliminate this explanation. The velocities of rise of pure nitrous oxide bubbles in dilute nitric acid were the same as the velocities of rise of insoluble nitrogen bubbles, even though the mass transfer-rate of nitrous oxide in the nitric acid solution was the same as that in pure water. This observation indicates that, although the phenomenon depends on the mass transfer-rate, it is also sensitive to the presence of electrolytes in solution. A simple explanation for all these phenomena that comes to mind is that electrokinetic effects caused by mass transfer might induce an electrically charged layer at the bubble surface, which in turn would retard the bubble motion by increasing the skin friction. This surface potential would be analogous to the zeta-potential, which is known to be sensitive to the presence of acids and alkalis, so that the presence of a zeta-potential would also explain the apparently anomalous case of nitrous oxide bubbles in aqueous nitric acid as well as the dependence of the phenomenon on the rate of mass transfer across the boundary. Furthermore, electrokinetic effects at the surface would explain why the phenomenon is only observed with small bubbles, where the surface effects would be large and inertial and profile effects would be small.

SCHULZE–HARDY RULE AND MASS ACTION LAW

By Prof. MIRKO MIRNIK

Rudjer Bošković Institute and the Department of Physical Chemistry,
Faculty of Sciences, University of Zagreb, Yugoslavia

IN two previous papers of this series[1,2] the equation:

$${}''c(1 - x)/{}'cx = 10^{({}'z - {}''z)a} = {}'D/{}''D = S \qquad (1)$$

was shown to be valid for the equilibrium concentrations ${}''c$ and ${}'c$ and for the adsorbed fractions, x and $1-x$ of two ions of valency ${}''z$ and ${}'z$ in equilibrium with the coagulated silver iodide. a is a constant, S the selectivity coefficient, ${}''D = x\gamma/{}''c$ and ${}'D = (1 - x)\gamma/{}'c$ are their distribution coefficients.

Equation (1) can formally be obtained from the difference of the equations:

$$\log {}'c = -\,{}'za + \log (1 - x)\gamma - \log {}^0D \qquad (2)$$

and

$$\log {}''c = -\,{}''za + \log x\gamma - \log {}^0D \qquad (3)$$

resp.

$$\log {}^0D = \log {}^iD - {}^iza \qquad (4)$$

where $\gamma = \overline{C}\,w/V$ is the maximal adsorbed amount expressed in equivalents per litre, w the amount of the solid in the system of volume V, $\overline{C}$ is the adsorbing capacity of the solid, that is, the amount adsorbed per unit amount of the solid, and ${}^0D$ is the distribution coefficient of a hypothetical particle of zero valency which would be adsorbed as charged particles.

The exchange of adsorbed counter ions can be represented by association processes between counter ions and the adsorbed potential determining ions:

$$(A_{{}^iz}M_{z^-}{}^{i})_{\text{ads.}} \rightleftharpoons ({}^iz\;A^{z^-})_{\text{ads.}} + z^-M^i$$

If chemical thermodynamics is applied to these association reactions the constants in equations (1) to (4) are obtained:

$$a/0{\cdot}4343 = \mu_{A^{z-}_{\text{ads.}}}/z^-RT$$

$$\ln {}^0D = (\mu^0{}_{AM^i_{\text{ads.}}}/z^- - \mu^0{}_{M^i})/RT$$

$$\ln {}'D = \ln a_{AM'_{\text{ads.}}}/a_{M'} = \ln(1-x)\gamma/c'$$

$$\ln {}''D = \ln a_{AM''_{\text{ads.}}}/a_{M''} = \ln x\gamma/c''$$

$$\ln {}^iD = \ln a_{AM^i_{\text{ads.}}}/a_{M^i}$$

for

$$z^- = 1,\ a_{AM'_{\text{ads.}}} = (1-x)\gamma,\ a_{AM''_{\text{ads.}}} = x\gamma,$$

$a_{M'} = {}'c, a_{M''} = {}''c$. $\mu_{A^{z-}_{\text{ads.}}}$ is the chemical potential of the potential determining ion in the double layer. The constancy of a with pI for different z, was established experimentally, therefore $\mu_{A^{z-}_{\text{ads.}}}$ is constant and independent of pI, while the adsorbed quantity of the potential determining ion is inversely proportional to pI (refs. 1–3). $\mu^0{}_{M'} = \mu^0{}_{M''}$ and $\mu^0{}_{AM'_{\text{ads.}}} = \mu^0{}_{AM''_{\text{ads.}}}$ are the standard chemical potentials of the counter ions M' and M'' of valency ${}'z$ and ${}''z$ in the solution and in the adsorbed layer and $a_{M'}$, $a_{M''}$ $a_{AM'_{\text{ads.}}}$ and $a_{AM''_{\text{ads.}}}$ are their activities.

By eliminating a in equations (2), (3) and (4) the following equation is obtained:

$$K_c = {}^0D^{({}'z - {}''z)} = {}'D^{{}''z}/{}''D^{{}'z} = [(1-x)\gamma/{}'c]^{{}''z}({}''c/x\gamma)^{{}'z} \qquad (5)$$

which is identical with the mass action law equation, K_c being its constant.

If ${}'c \gg {}''c + \gamma x$, then $x \ll 1$ and $1-x \doteq 1$ and equation (5) can be written:

$$\log 1/{}''D = {}''z/{}'z \log {}'c - {}''z/{}'z \log \gamma K_c{}^{-1/{}'z} \qquad (6)$$

Equation (6) is identical with Strickland's expression[4] suggested for the determination of ion charges and was used by Kraus and Nelson[5] and others[6] for this purpose.

Consequently, the coagulated silver iodide may be considered as an ideal ion exchanger, the role of the coagulating ions being that of the exchange ions.

Supposing that two ions are exchanging in accordance with coulombic repulsion forces, one of valency ${}'z = 0$, the other of ${}''z = z$, then equation (1) may be written as:

$$\log c/{}^0c = -\,az + \log x/(1-x) \qquad (7)$$

The logarithm of the concentration at which a given constant ratio of two ions is adsorbed (x = constant) is increasing linearly with the decreasing valency of the ion. ${}^0c$ can be considered as a concentration of a hypothetical adsorbable species without charge, which follows from equation (7) for known x, z and c.

It is a general opinion that the Schulze–Hardy rule should be a consequence of the relative adsorption tendencies of the coagulating counter ions of different valencies. The coagulation value $c_{\text{coag.}}$ is an experimentally observed limiting concentration at which the coagulation sets in abruptly, and all terms determining it must be constant. The positions which are in the double layer of the coagulated silver iodide occupied by coagulating counter ions have to be occupied on the stable silver iodide by stabilizing particles. In a simple system like the system AgI—I^-—H_2O—counter ion, the only particles which can be considered as stabilizing are the water molecules. The adsorbed quantity of remaining species, the I^- ions, does not depend on the concentration of the counter ions and cannot be made responsible for coagulation. The coagulation will be induced when the stabilizing water molecules are exchanged by the coagulating counter ions. The reactions representing this process in the double layer can be written:

$$(A_zM_{z^-})_{\text{ads.}} \rightleftharpoons z\,A^{z^-}{}_{\text{ads.}} + z^-M$$

$$(A_2{}^{z^-}.z^-H_2O)_{\text{ads.}} \rightleftharpoons 2\,A^{z^-}{}_{\text{ads.}} + z^-\,H_2O$$

Chemical thermodynamics applied to these association reactions gives the equation (3) for $z^- = 1$ with equal constants, a and ${}^0D$, namely:

$$\log c_{\text{coag.}} = -\,za + \log x_{\text{coag.}}\gamma/{}^0D \qquad (8)$$

for:

$$a = (\mu_{(A_2{}^{z-}z^-H_2O)_{\text{ads.}}}/z^- - \mu_{H_2O})0{\cdot}4343/2RT =$$

$$\mu_{A^{z-}_{\text{ads.}}}\ .\ 0{\cdot}4343/z^-RT$$

$$\ln {}^0D = (\mu^0_{(AM)_{\text{ads.}}}/z^- - \mu^0_M)/RT$$

$\mu_{(A_1{}^{z^-}.x\text{-}H_2O)_{\text{ads.}}}$ is the chemical potential of the hydrated potential-determining ion in the double layer. It is constant because both $\mu_{A^{z-}_{\text{ads.}}}$ and μ_{H_2O}, the chemical potential of water in the liquid phase, are constant. ^{0} stands for the respective standard chemical potentials. Equation (8) should represent the Schulze–Hardy rule and is according to the adsorption theory, thermodynamically justified. Any other non-linear ($\log c_{\text{coag.}} - z$) relationship would contradict the requirements of thermodynamics.

A linear relation between the logarithm of coagulation value and valency was deduced theoretically by Težak[7,8] and was confirmed experimentally[7,9]. On the basis of this linear relationship, Težak *et al.*[9,10] suggested a coagulation value method for the determination of ion charges.

It was shown experimentally[1,2] that the slope of the Schulze–Hardy line in equation (8) and the slope of the adsorption line for $x/(1-x)$ = constant in equation (7), namely, the a values, are equal for the negative silver iodide system. Consequently, Strickland's and Težak's methods can be considered as the consequence of the same adsorption-desorption, respectively, ion exchange equilibria for which the mass action law is valid. The equality of a is thermodynamically justified, since a is proportional to the chemical potential of the adsorbed potential determining ions, which is the same in both cases.

If the coagulation value represents that activity of the coagulating ion in solution at which, in the double layer, its chemical potential becomes equal to the chemical potential of the stabilizing particles, then $x_{\text{coag.}} = 0{\cdot}5$.

Since ${}^0D$ cannot be determined by adsorption experiments on coagulated silver iodide (for $c > c(x = 1)$ ${}^0D$ is not constant) it follows from coagulation experiments:

$$\log {}^0D \doteq -za + \log 0{\cdot}5\,\gamma/c_{\text{coag.}}$$

I wish to express my thanks to Prof. Božo Težak for his interest in my work and for many helpful discussions.

PHOTOCHEMICAL REACTIONS IN FROZEN SOLUTIONS

By Prof. SHIH YI WANG

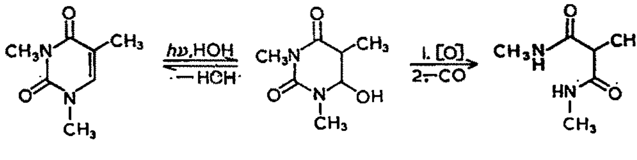
Department of Physiology, Tufts University School of Medicine, Boston, Mass.

SZENT-GYÖRGYI has shown that photochemical reactions in aqueous solutions, in frozen aqueous solutions and in frozen aqueous solutions containing organic solvents differ from each other[1]. He has recently suggested[2] that a photochemical reaction in frozen solution differs from that in liquid solution because the formation of crystalline ice forces the solute molecules into solid aggregates[3]. In confirmation of this hypothesis, he found that the phosphorescence observed in frozen solution also occurs in a dry film. Similarly, I have obtained chemical evidence that an identical photoproduct was isolated from the irradiation of pyrimidines, either in frozen solutions or as dry solid films. However, the photoproduct obtained from the irradiation of aqueous solution was different.

By extending the hypothesis of molecular aggregate formation in frozen solution, one would expect that the photochemical behaviour of a solute in frozen aqueous solution containing organic solvent would be similar to that of its organic solution; for on freezing, the organic solvent and solute molecules would be excluded from the water crystals and form 'puddles'. That the photochemical reaction actually occurs in such 'puddles' of organic solvent has been adduced from the fact that the methanolic addition product of 1,3-dimethyluracil is formed from the irradiation of 1,3-dimethyluracil either in frozen solution containing 2 per cent methanol or methanolic solution.

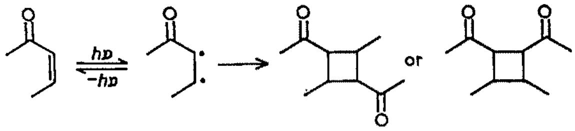
From this work, two novel techniques of great interest for photochemical study are evident: (1) frozen solution irradiation may be used as an efficient method for irradiating solids; (2) formation of 'puddles' may offer a new means for study of low-temperature photochemical reactions.

In an earlier report from this laboratory on the effect of ultra-violet irradiation on 1,3-dimethylthymine (DMT) in aqueous solution, it was suggested that a water addition product is the first intermediate formed. The intermediate is probably unstable at room temperature and reconverted to its starting material by dehydration[4]. It is not unreasonable to expect that this intermediate would become stable at low temperatures and could be isolated. In order to prove the above, an examination of low-temperature irradiation was initiated.



In frozen solution, the absorption maximum of DMT decreased rapidly when irradiated with ultra-violet light. This is to be expected if the hydration product were formed. The original spectrum would then be reconstituted by standing at room temperature. However, the product obtained from frozen solution irradiation was stable even when treated with acid, base or heat. It must be concluded that the assumed product, 6-hydroxy-1,3-dimethylhydrothymine, was not formed. This observation indicated that irradiation with ultra-violet light in aqueous solution and in frozen solution must proceed through two different mechanisms. In order to eliminate the possibility that temperature played a part in the alteration of reaction pathways, the irradiation of DMT was carried out in the aqueous solution and in the frozen solution, both at ~0°. Since this difference in irradiation behaviour still was observed, it can be concluded that temperature alone is not the cause of the difference.

In order to further our understanding of the nature of frozen solution irradiation, the isolation and identification of the product were carried out. From the elementary analysis and molecular weight determinations, the product was readily recognized to be a dimer of DMT[5].



Photodimerization has been widely observed for α,β-unsaturated keto-derivatives[6]. These dimers are generally believed to be formed through the union of the double bonds from two molecules. A diradical intermediate, as shown, is generally favoured as the mechanism for the formation of the cyclobutyl ring. The probability of dimer formation will depend on the distance between the two reacting molecules. Therefore, photodimerizations occur mostly in the solid state rather than in solution. Since highly strained cyclobutyl rings are formed in this process, the photoproducts are known to be quite unstable. It is reported that photodimers are reconverted to their monomers by treatment with either acid[7] or heat[8] or ultra-violet light[9]. DMT-dimer obtained in frozen solution irradiation, as noted above, is stable toward heat, acid or base, but ultra-violet light converted it to the monomer, DMT, in liquid solution.

Since the DMT-dimer is formed by the irradiation of frozen solution, irradiation of frozen solution must resemble irradiation of solid aggregates. Further evidence for this assumption will be presented in the ensuing sections.

(A) Nature of Irradiation of Frozen Solutions

(1) *Heterogeneity of Frozen Aqueous Solutions.* The heterogeneity which serves as the basis for the hypothesis that solid aggregates are formed on freezing aqueous solutions is analysed quantitatively as follows: Frozen solutions of DMT and 1,3-dimethyluracil (DMU) were analysed spectrophotometrically; they showed differences in their concentrations between different layers. Optical density readings for a 0·1 m*M* solution after freezing are given in Table 1.

Table 1

Layer*	Dry-ice mixture		Liq. N_2	Ice-NaCl	Freezer
	DMT	DMU	DMT	DMU	DMT
Outermost	0·66 × 10^3	0·42	0·74	0·49	0·21
Intermediate	1·08	1·10	1·04	1·04	0·82
Core	1·12	1·16	0·96	1·15	1·78

* When a beaker containing solution is frozen, crystals of ice will form first on the surface of the beaker and grow towards the centre. However, when such a beaker is placed instead in a tray, which in turn is placed directly on the metal shelf in a refrigerator, the top layer freezes first. Therefore, the reverse effect was observed (Table 2).

The concentration difference is often 8–10 times between two layers for compounds such as uridine, thymidine, etc.

After irradiation the frozen solutions were also analysed as three separate layers. For example, a thymine solution (0·1 m*M*, $\varepsilon^{H_2O}_{\text{max.}}$ 0·78 × 10^3), gave the readings presented in Table 2.

Table 2

Layer	$\varepsilon^{H_2O}_{\text{max.}}$		Yields (per cent)	
	Before irrad.	After irrad.	Relative	Absolute
Outermost	1·53	0·19	169	88
Intermediate	0·70	0·10	76	86
Core	0·17	0·02	19	88

The relative percentage yields of dimer were calculated assuming homogeneous distribution of solute while the absolute yields were calculated on the basis of the real concentration in each layer. The relative percentage yields were found to be variable. However, when the percentage yields were calculated according to the concentration of each layer, that is, the absolute amount of material present in each layer, then the absolute percentage yields were almost the same throughout. This result suggests that the irradiation is related to the absolute amount of material present.

(2) *Effect of Temperature and Methods of Freezing on Irradiation Reaction.* When individual solutions were frozen under different conditions such as in a 'deep-freeze', or by means of liquid nitrogen or carbon dioxide-2-*n*-butoxyethanol, and then irradiated at identical temperatures in a carbon dioxide-2-*n*-butoxyethanol mixture bath, the results obtained were approximately the same. In addition, when all solutions were frozen in a dry-ice mixture but the irradiation temperature of each solution was varied by means of liquid nitrogen, carbon dioxide mixture or ice-sodium chloride baths, the decrease in absorption maximum was still the same (Table 3).

Table 3

Effect of method of freezing (DMU)

$O.D.^{H_2O}_{\text{max.}}$	In ice-NaCl	In CO_2 mixture	In liquid N_2
Before irradiation	0·973	0·965	0·960
After irradiation	0·703	0·683	0·706

Effect of temperature during irradiation (DMT)

$O.D.^{H_2O}_{\text{max.}}$	– 10°	– 70°	– 190°
Before irradiation	0·838	0·838	0·840
After irradiation	0·390	0·394	0·419

Therefore, neither the temperature during irradiation nor methods of freezing altered the photochemical behaviour of solid aggregates in frozen solutions.

One attempt was made to form a homogeneous frozen solution by dropwise freezing with dry-ice mixture. Each individual drop was added after the previous drop was completely frozen; nevertheless, dimers were formed on irradiation. These findings suggest that within the means of common laboratory facilities, heterogeneity always results when an aqueous solution is frozen.

(3) *Irradiation in Rigid Medium*[10]. In order to demonstrate that no dimerization should occur in the absence of molecular aggregates, glycerol was used as the solvent for the irradiation study. On cooling,

the glycerol solution of DMT became rigid glass rather than crystalline and the individual molecules were on the average 100 Å. apart[10]. On irradiation, the absorption maximum of DMT remained the same as before irradiation, indicating strongly that no photodimerization occurs in a homogeneous solution.

(4) *Formation of Dimers in Frozen Aqueous Solutions and Films of Dry Solid.* (*a*) Irradiation in frozen solution[11–13]. Under my experimental conditions, all the uracil and thymine derivatives tested form photodimers. Therefore, this is a general phenomenon for pyrimidine molecules which have α,β-unsaturated ketone as their predominant electronic configuration. Table 4 gives some of the compounds which have been irradiated as frozen solutions. Also given is the maximum percentage decrease at $\lambda_{max.}$ for each compound and its time for reaching this maximum decrease. Based on these two values, the quantum yields were calculated. The light energy absorbed by the solution is $1 \cdot 24 \times 10^{-6}$ Einstein per minute under this condition.

Table 4

0·1 m*M* solution	Maximum decrease in $\lambda_{max.}$ (per cent)	Minimum time (min.)	Quantum yield* × 10^{-3} (mole/Einstein)
Thymine	86	3	230
1,3-DMT	75	6	100
Thymidine	49	100	4·0
Ca^{++}-thymidylate	41	120	2·8
Uracil	68	10	55
1,3-DMU	25	15	13
Uridine	21	90	1·9
Uridylic acid	40	150	2·2
6-Methyluracil	60	80	6·0
1,3,6-Trimethyluracil	50	45	9·0

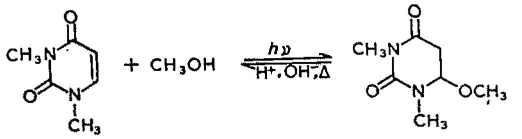
* These values are provided to indicate the order of magnitude of the quantum efficiency of the reactions. The fact that some of the light is reflected from crystalline ice surfaces renders it difficult to assign a 'true' value of light-energy absorbed by the frozen solution.

Evidence for the formation of dimers is based on the isolation and characterization of uracil-dimer (anal. found C, 42·61; H, 3·29; N, 25·16. No absorption maximum between 220–360 mμ), DMT-dimers (Isomer-I: m.p. 258–259°; mol. wt. found 301; anal. found C, 54·56; H, 6·61; N, 18·34. Isomer-II: m.p. 225–226°; mol. wt. found 302; anal. found C, 54·67; H, 6·73; N, 18·28), and thymine-dimer[13] (anal. found, C, 47·47; H, 4·69; N, 22·23. No absorption maximum between 220–360 mμ). Other photodimers were shown by the decrease of their absorption maxima during irradiation with ultra-violet light in frozen solutions. After thawing, the original spectra could be reconstituted by the irradiation of the thawed solution with ultra-violet light at *p*H ~2 (acid *p*H used to prevent the formation of the water addition product during the irradiation of aqueous solution whenever necessary).

(*b*) Irradiation of dry solid films. The question still remains, Does dimerization occur because the solute is present in dry aggregates in a frozen solution, as suggested above, or is there some more subtle reason? If only dry aggregates are required then irradiation of a dry solid film should yield similar results. When a thin layer of solid thymine or uracil was irradiated, thymine-dimer or uracil-dimer was isolated from these irradiation studies; these dimers were characterized by ultra-violet and infra-red spectra, and were found to be identical to those obtained when frozen solutions were irradiated. Not only do the foregoing results support the proposed concept, but they also emphasize that the crystalline structure of water is not necessary for the photochemical behaviour noted for frozen solution. Frozen solution irradiation offers a novel method of solid irradiation which is experimentally advantageous; it is convenient, controllable, involves neither the tedious technique nor the large quantities that are ordinarily necessary for chemical studies of irradiation reactions using dry solid.

(B) Photochemistry in 'Puddles'

Szent-Györgyi showed that the photochemical behaviour of a compound irradiated in a frozen aqueous solution is altered when the frozen solution contains 2 per cent methanol. He stated "... an admixture of 10 per cent glycerol or 2 per cent methanol to the water deprive it of its specific action on excitation because these admixtures destroyed the regularity of the water crystals"[1]. In my frozen-solution experiments, when thymine and DMT were irradiated in the presence of 2 per cent methanol or 10 per cent glycerol, the spectra were the same before and after irradiation, a finding strongly indicating that no reaction has occurred. However, since heterogeneity of the frozen solution was shown to be responsible for the photodimerization, a 'puddle effect', again based on heterogeneity, is proposed to explain the above phenomena. One may hypothesize that, on freezing, the water molecules tend to crystallize, but the solute molecules, together with some of the added methanol or glycerol, are excluded from the water to form puddles. However, 'glycerol puddles' are different from 'methanol puddles'. As noted above, the former when frozen form a rigid medium, and as a result no photodimerization should occur on irradiation. The latter when frozen form a methanolic solution, and therefore a photochemical reaction in this solution should be observed. In order to show the 'puddle effect' of methanol, a compound that fulfils the following criteria must be studied: (*a*) forms a photodimer when irradiated in frozen solution; (*b*) forms a solvent addition product when it is irradiated in solution. A compound with the above characteristics was found in DMU. When DMU dissolved in methanol is irradiated with ultra-violet light, the decreasing absorption maximum of DMU indicates the formation of 6-methoxy-1,3-dimethylhydrouracil



The addition of acid or alkali will cause 6-OCH_3 compound to revert to DMU[14]. When a frozen aqueous solution of DMU containing 2 per cent methanol was irradiated, a decrease in absorption maximum was also observed. Again, addition of acid (*p*H ~2) or alkali (*p*H ~12) caused a total reconstitution to DMU, as shown by the ultra-violet spectrum. This fact indicates that the solvent addition product was formed, which strongly supports the 'puddle effect' hypothesis. Therefore, Szent-Györgyi's observation that irradiation of a frozen solution containing 2 per cent methanol was similar to that of a liquid solution is to be expected[15].

(Irradiation of dilute solutions of 0·1 m*M* rhodamine *B* (Table 5, *B*), 0·1 m*M* flavine mononucleotide

Table 5

State	*B*	FMN	Mixture
Liquid solution	Orange	Yellowish green	Orange
Frozen solution	No light emission	Orange	Bright pink
Frozen solution + 2 per cent MeOH	Orange	Yellowish green	Orange
Solid film	No light emission	Orange	Bright pink

(FMN) and a mixture of 0·1 m*M* rhodamine *B* and 1 m*M* thiamine hydrochloride were used by Szent-Györgyi to demonstrate the dramatic changes in fluorescent colours between the frozen solutions and their liquid counterparts[1]. I have extended these experiments by the comparison of these fluorescent colour changes with solid films. These were prepared by drying 10 m*M* methanolic solutions of *B*, 10 m*M* methanolic solution of the mixture and a saturated methanolic solution of FMN on glass plates. Table 5 shows the changes in colour viewed under an ultra-violet lamp (Mineralight No. *R*. 51, Ultraviolet Prod. Co., San Gabriel, Calif.). The light emission from liquid solutions and frozen solutions with 2 per cent methanol is the same, suggesting that the 'puddle' formation probably occurs in the latter. The light emission from solid films is the same as that of their frozen solutions, suggesting that the fluorescent colours observed with frozen solutions probably is due to the formation of solid aggregates on freezing.)

This 'puddle' formation in frozen solution certainly merits further investigation. This system resembles the non-aqueous environments of living organisms which permit the occurrence of specific reactions, such as electron transport in mitochondria[15] and oxygen exchange in hæmoglobin[16]. By replacing 2 per cent methanol with various organic solvents, one may experiment with the molecular rearrangements, Diels–Alder reaction, etc., of various compounds. The formation of 'puddles' produces an essentially water-free medium at low temperatures for the reactions under investigation, a condition impractical to achieve by merely cooling organic solvents because of water condensation. It is my belief that this 'puddle effect' probably offers a new area for photochemical study.

At the outset of my systematic study of the photochemistry of nucleic acids and related compounds, I considered that photochemical changes occurring in the solid-state may possibly be related to the irradiation-induced changes of deoxyribonucleic acid (DNA) in biological systems. This concept is based on the Watson and Crick[17] and Wilkins *et al.*[18] proposal for the molecular structure of DNA. They suggested that DNA may consist of two polynucleotide chains helically wrapped around each other with 10 base residues per turn. The pitch is 34·6 Å. and the distance between the two layers of base residues is 3·4 Å. Thus, the proximity of the bases may permit the interaction of two adjacent base residues on the same chain to form pyrimidine-pyrimidine, purine-purine or pyrimidine-purine dimers coincident with the breaking of interchain H-bonds. The conditions for the irradiation of solid films, discussed above, for the yield of pyrimidine-dimers were obtained only after an understanding of the nature of the irradiation of frozen solutions was attained. Therefore, if biological systems and compounds such as chloroplasts, proteins and nucleic acids are closely related to the 'pseudocrystalline' state, the irradiation of solids or frozen solutions may yield more important information than irradiation in other media.

Irradiator. A bank of seven ultra-violet lamps (General Electric Germicidal tube *G*15*T*18) was used. The distance between the lights and the solution for irradiation was 33 cm. A voltage regulator was connected to the irradiator and a light intensity of 50 MW./sq. ft. was obtained[19]. For isolation study, the voltage regulator was omitted and a light intensity of 80 MW./sq. ft. was used.

Quantum Determination. This was measured by the method of Forbes and Heidt[20].

Frozen Solutions. Ten ml. of solution in a 50-ml. beaker was frozen by various means and the thickness of the solution was about 1 cm.

Separation of Layers. Fifteen ml. of frozen solution in a 100-ml. beaker was used (1 cm. thickness). It was thawed gradually by placing the beaker in a water bath at room temperature. Some of the thawed liquid was pipetted out until 5 ml. could be obtained. This was referred to as the outermost layer. Then, with further thawing, a second 5 ml. portion, the intermediate layer, was collected. The remainder was called the core layer.

Gross Irradiation for Isolation. One litre of 1 m*M* solution was frozen and then was irradiated in an enamel pan (11·5 × 18 in.) for 30 min. This pan was placed on a dry-ice mixture to keep the bath frozen. The irradiated solution was then thawed and was evaporated to dryness with a flash evaporator for further purification. Usually, the product of several runs was combined.

(*a*) *Uracil-dimer, thymine-dimer.* The crystalline residue was taken up in boiling water. After filtration, the filtrate was concentrated for crystallization. The crystalline product was obtained easily because the dimers are much more insoluble in water than the monomers.

(*b*) *DMT-dimers.* The crystalline residue was taken up in chloroform, and, after filtration, the combined solution from 3 pans was concentrated to 5 ml. To this an adequate volume, 25 ml., of petroleum ether (30–60°) was added to make the solution just appear cloudy. On standing, a crystalline product was obtained, m.p. 210–230°. Every 100 mgm. of the above product was dissolved in 2 ml. of chloroform and then 5 ml. of petroleum ether was added for crystallization. From this 45 mgm. of a product, m.p. 250–255° was obtained. Further crystallization of this product gave a high melting isomer, m.p. 258–259°. From the crystallization of the mother liquor, a low melting isomer, m.p. 225–226°, was obtained.

Irradiation of Solid Film. A 10-m*M* methanolic solution of thymine or uracil was prepared, and 5 ml. of this solution was pipetted on to a 'Pyrex' baking pan (9 × 12 cm.) very slowly and allowed to form an even, dry film over the bottom of the pan. After irradiation for 30 min., the residue was taken up in boiling water and then concentrated for crystallization.

(*a*) *Thymine.* A total of 5 mgm. of thymine-dimer was obtained by combining 5 runs. (*b*) *Uracil.* A total of 7 mgm. of uracil-dimer was obtained by combining 8 runs.

I wish to thank H. Keith Johnson, Mary Mouyos, Andrew Rodrigues, Milda Strikaitis and Catherine Tung for their collaboration in this work.

MECHANISM OF SODIUM TRANSPORT IN CELLULAR MEMBRANES

By JOHAN JÄRNEFELT

Research Laboratories of the State Alcohol Monopoly (Alko), Helsinki

THE function of a nerve cell in the process of conducting impulses can easily be described by the behaviour of its membrane potential. At rest, the potential difference, outside minus inside, is about +50 to +100 mV. During activity, when an impulse passes, this potential is rapidly abolished and even to some extent reversed. Afterwards, and within a few milliseconds, the original potential difference is re-established. The wave of changes in potential is termed the action potential.

It has been shown very convincingly that the first, decreasing phase of the action potential is due to the sudden and very rapid transfer of sodium ions from the outside to the inside of the cell membrane[1]. This movement of sodium ions occurs in the direction of the concentration gradient, and thus needs no additional source of energy. The rising phase of the wave is due to an outward movement of potassium, which is again in the direction of the concentration gradient. Ultimately, the repetition of this event would lead to the destruction of the ionic concentration gradients, and thus to the loss of the ability to form an action potential, or in other words, to a block in the excitability and function of the nerve cell. However, the nerve cell membrane possesses a mechanism which is capable of transporting sodium ions from the inside to the outside, against the concentration gradient[1]. Thus this gradient does not disappear, but is eventually re-established to its full extent.

When one tries to understand the basic principles of these processes, two things have first of all to be explained: (1) the ability of the cell membrane to bring about and to maintain the concentration differences of ions on its two sides; (2) the nature of the changes which occur in the membrane permiting sodium ions to enter the cell and thus cause the action potential. As regards the first problem, it must be borne in mind that the different concentrations of sodium ions on the two sides of the membrane are in a dynamic equilibrium. There is a continuous exchange of sodium ions through the membrane, but at rest the concentrations remain constantly the same[1]. The outward movement of sodium ions is dependent on an active transfer mechanism which needs metabolic energy for its function. This energy is supplied in the form of adenosine triphosphate[1], which is in turn generated through the process of oxidative phosphorylation.

The second problem, that of the mechanism of formation of the action potential, is concerned with a sudden increase in the inward movement of sodium ions. The nature of the changes in the membrane which cause this phenomenon is still quite obscure. The discussion which follows is concerned with the mechanism of active transport of sodium ions across the cell membrane. Some new data on the nature of the biochemical mechanism underlying the phenomenon of active transport will also be presented and discussed.

Microsomal Adenosine Triphosphatase as an Indicator of Sodium Transport

Recently, evidence[2-7] has been obtained which bears on the mechanism of sodium transport across the cell membrane. This evidence also provides a plausible explanation for the mode of action of general narcotics such as ethyl alcohol[5] and ether. Some implications concerning present thought on biochemical phenomena in highly organized subcellular structures are also evident.

Microsomes from rat brain, when isolated in the manner described in detail elsewhere[3], exhibit a powerful adenosine triphosphatase activity. This activity is completely dependent on magnesium ions, and shows the property of being stimulated by sodium ions (Table 1). When sodium is present in concentrations of between 30 and 100 m*M*, there is observed an activity of adenosine triphosphatase of some 20–25 per cent higher than the activity in the absence of sodium. Somewhat lower concentrations of sodium show a lower stimulation, and concentrations less than 5 m*M* do not stimulate to a measurable extent. To find an explanation for these observations, attention is directed to the well-known phenomenon of respiratory control in electron-transport-coupled phosphorylation, catalysed by mitochondria. When phosphate and phosphate acceptors are absent, no electron transport occurs. In the brain microsomal system, less dephosphorylation of adenosine triphosphate occurs in the absence of sodium. On the basis of these experiments, it is assumed that microsomes from rat brain catalyse two enzymatic reactions, one of which has adenosine triphosphate as a substrate, the other sodium ions. These two reactions would be coupled to each other in an obligatory manner, just as are electron transport and phosphorylation in the mitochondrial system. When no sodium ions are present, no reaction could occur with adenosine triphosphate, and a control mechanism analogous to the mechanism of respiratory control would therefore be in operation. Obviously the reaction with sodium cannot occur in a sodium-free medium, and the consequence is a lower rate of adenosine triphosphate dephosphorylation. The fact that the latter activity is not completely extinguished in the absence of sodium is capable of explanation when one considers that the microsomes may have suffered damage during the preparation, and that such damage is likely to produce a certain amount of 'uncoupling'. It is also possible that enough sodium is bound to the microsomes to cause the observed rate in the absence of sodium.

	K^{+}, 0·015 *M*	0·44	0
	Na^{+}, 0·05 *M* and K^{+}, 0·05 *M*	0·57	+ 0·13

The assay contained : 20 m*M* *tris*-chloride buffer, *p*H 7·5, 5 m*M* magnesium chloride, 5 m*M* *tris*-adenosine triphosphate, 0·1 ml. of enzyme suspension in isotonic sucrose, the indicated amounts of the alkali metal ions as chlorides, and when these would not make the mixture isotonic, the necessary amount of sucrose. Final volume 1 ml., temperature 30° C., incubation time 10 min.

In this connexion, it is interesting to note that potassium ions cannot cause a stimulation in the microsomal adenosine triphosphatase (Table 1). The view has been adopted that the isolated microsomal system represents and contains the sodium-specific mechanism for the transport of ions across cellular membranes. Some evidence from other laboratories can be taken as supporting this view. Some years ago, Skou demonstrated[6] that submicroscopic particles from crab nerve possess a sodium-and-potassium dependent adenosine triphosphatase activity. He also interpreted this as an expression of an active sodium transport mechanism in these particles. Skou's results indicated that the sodium-dependent mechanism was also dependent on small amounts of potassium ions, a finding which is at variance with the results obtained in this work[2,3]. It is quite possible that the microsomal preparation contained enough potassium to mask any existing effects of this ion, and the discrepancy between the findings of Skou[6] and those of this work[3] may therefore not be important. Quite recently, Post *et al.*[7] reported on a sodium-and-potassium dependent adenosine triphosphatase in erythrocyte membrane fragments which very much resembles the enzyme from crab nerves[6] and from brain microsomes[3]. Hanzon and Toschi[8] showed that the microsomes obtained in the fractionation of brain homogenates were derived from membranous structures in the cytoplasm, the endoplasmic reticulum or the α-cytomembranes. These are probably continuous with the outer cell membrane, and probably structurally and functionally identical with it. In addition, Toschi found[9] that the acetylcholinesterase was concentrated in the microsomal fraction, thus suggesting an important functional role for this fraction in the impulse-cycle. On different lines, Hokin and Hokin[10] have postulated a mechanism for sodium transport across cellular membranes. Their views are based on the mechanism for the incorporation of phosphate into phosphatidic acids of brain microsomes. The phosphatidic acids would function as sodium carriers in the internal lipide phase of the cell membrane. The overall process results in a hydrolysis of adenosine triphosphate.

Table 2. INHIBITION OF ACTIVITY OF ADENOSINE TRIPHOSPHATASE BY PYRIDINE ALDOXIME DODECYLIODIDE[4]

Exp. No.	Additions	μmoles P_i liberated			
		in absence of Na^{+}	Act. (+), inh. (−)	in presence of 0·1 *M* Na^{+}	Act. (+), inh. (−)
1	None	0·75	–	0·93	+ 0·18
	PAD, 10^{-4} *M*	0·47	– 0·28	0·47	– 0·46
	PAD, 10^{-4} *M* and Eserine 10^{-4} *M*	0·49	– 0·26	0·49	– 0·44
	Eserine 10^{-4} *M*	0·81	+ 0·06	0·94	+ 0·01
2	None	0·72	–	0·85	+ 0·13
	PAD, 3×10^{-5} *M*	0·71	– 0·01	0·72	– 0·13

The assay conditions were as in Table 1.

Note added in proof. More recent experiments have shown that the stimulation of the microsomal ATPase by sodium ions can be considerably increased by the presence of small amounts of potassium. Nevertheless, potassium alone has no effect. These findings abolish the main discrepancy between Skou's work[6] and mine.

Inhibition of the Adenosine Triphosphatase

The behaviour of the sodium-dependent microsomal adenosine triphosphatase was also studied in the presence of some substances which are known to cause a depolarization of the cell membrane, and which are accordingly of interest in connexion with the problem of active sodium transport and impulse formation. Acetylcholine showed no effect on the adenosine triphosphatase activity, either alone or in the presence of eserine, which would inhibit the acetylcholinesterase. On the other hand, the quaternary nitrogen compound pyridine aldoxime dodecyliodide (PAD) strongly inhibited the activity of adenosine triphosphatase (Table 2). The inhibition showed different characteristics in the absence and in the presence of sodium. If a suitable concentration of about $3 \times 10^{-5} M$ was chosen, only the sodium-stimulated adenosine triphosphatase was inhibited, and the remaining activity still exceeded that obtained in the absence of sodium; the unstimulated activity was not affected at all. If the concentration of PAD was increased, the inhibition also became noticeable in the sodium-free experiments. In each case where the inhibitor concentration was sufficiently high to cause inhibition in the sodium-free experiments, the remaining activity was the same, irrespective of the presence or absence of sodium. Such behaviour suggests that the reaction is sub-maximal in absence of sodium and that PAD specifically inhibits an enzymatic reaction which is involved in the splitting of ATP. As will be seen later, another type of inhibition of the adenosine triphosphatase can also be obtained.

Dettbarn *et al.*[11,12] have shown that PAD depolarizes the nerve cell membrane. They assume that the depolarizing action of PAD is due to the fact that this substance is analogous to acetylcholine in structure. It has indeed been shown[13] that its action on acetylcholinesterase can be explained on the basis of this molecular analogy. The foregoing experiments show that PAD inhibits the microsomal adenosine triphosphatase in a specific manner, suggesting that PAD directly interferes with the mechanism of reaction. According to the views of Nachmansohn *et al.*[14], this would mean that acetylcholine should also cause a similar inhibition. The fact that this is not so is perhaps not too serious an obstacle, if the lipide insolubility of acetylcholine is taken into account. A more serious obstacle, however, is the fact that eserine does not block the inhibition by PAD. In Dettbarn's experiments[12], eserine blocked the effect of PAD, and this effect is one of the main points in his argument for an analogy between PAD and acetylcholine.

Grundfest[15] has suggested that the inhibition of the mechanism of sodium transport is a cause of the action potential. However, such a mechanism does not seem to be sufficient to explain the great speed of the inward sodium flow during the action potential. It has been pointed out by Katz[16] and by Hodgkin and Keynes[1], that a mere inhibition of the active transport mechanism would not provide a quantitatively satisfactory basis for this phenomenon. However, as the experiments described here suggest that the active mechanism of sodium extrusion from the cell is inhibited by acetylcholine analogues, the role of this substance in the formation of the action potential in a manner closely related to that suggested by Grundfest cannot be ruled out completely.

Non-Specific Inhibitions

In addition to PAD, a number of other substances cause a decrease in the rate of hydrolysis of adenosine triphosphate by brain microsomes. Detergents, alcohols, and the anæsthetics ether and chloroform are such substances. The type of inhibition acquired with these compounds is quite different from that obtained by PAD. While the behaviour of the adenosine triphosphatase in the presence of PAD suggested a specific mode of action for this compound, no such specificity seems to be involved in the case of the other substances. Thus the same concentration of an inhibitor, for example, deoxycholate, causes about the same amount of inhibition, irrespective of whether sodium is present or not. The remaining activity is thus always, within certain limits of inhibitor concentration, higher in the presence of sodium than in its absence. It is of particular interest that dodecylsulphate, a detergent with the same lipophilic alkyl group as PAD, also causes this type of non-specific inhibition (Table 3). The role of the dodecyl group as the inhibitory principle in PAD can thus be ruled out, and the quaternary nitrogen assumes a dominant position as the active grouping in this compound. The analogy between PAD and acetylcholine is thus strengthened, and support is given to the possibility of an inhibition of the sodium transport mechanism by acetylcholine.

Table 3. INHIBITION OF ADENOSINE TRIPHOSPHATASE BY SODIUM DODECYL-SULPHATE (DS)[4]

	μmoles P_i liberated			
Additions	in absence of Na^+	Act. (+), inh. (−)	in presence of 1·0 M Na^+	Act. (+), inh. (−)
None	0·75	–	0·93	+ 0·18
DS 10^{-4} M	0·59	− 0·16	0·72	− 0·21

The conditions were as described in Table 1.

Table 4. THE EFFECT OF ETHYL ETHER AND CHLOROFORM ON THE MICROSOMAL ADENOSINE TRIPHOSPHATASE

	μmoles P_i liberated			
Additions	in absence of Na^+	Act. (+), inh. (−)	in presence of 0·1 M Na^+	Act. (+), inh. (−)
None	0·73	–	0·81	+ 0·08
Ether 0·02 M	0·68	− 0·05	0·75	− 0·06
Ether 0·04 M	0·66	− 0·07	0·73	− 0·08
Chloroform 0·01 M	0·62	− 0·11	0·70	− 0·11

The conditions were as described in Table 1.

It is interesting to note that in addition to the above-mentioned detergents, compounds such as alcohols, ether and chloroform cause a non-specific inhibition of the microsomal adenosine triphosphatase (Table 4). The concentrations of these compounds used in the experiments are approximately such as would occur during heavy alcohol intoxication or during anæsthesia. The effects observed with these substances offer a new and interesting possibility of explaining their mechanism of action on a biochemical basis. First, it is known that ethanol causes a decrease in the resting membrane potential of the nerve cell[17]. Secondly, the rate of adenosine triphosphate hydrolysis is diminished by ethanol[4]. This leads to a smaller quantity of adenosine diphosphate being formed, and thus, through the well-known mechanism of respiratory control in mitochondria, to a decrease in the rate of oxygen consumption. This is in very close agreement with findings on the effect of ethanol on the oxygen consumption of the whole brain or brain slices[18]. The biochemical mechanism of the action of alcohol and of anæsthetics thus seems now to be within the reach of studies on a subcellular level.

Mechanism of the Non-Specific Inhibition

It was explained above that the inhibition by PAD of the sodium-dependent adenosine triphosphatase seems to be due to a specific inhibition of the adenosine triphosphatase reaction. The inhibition caused by the other substances mentioned above is of another type, and could not be interpreted as an inhibition in the classical manner. The mechanism of this inhibition therefore remains to be explained. All the substances tested are lipophilic in character, and would have a considerable affinity for the lipide structures forming the major part of the microsomal mass. A certain structural disorganization undoubtedly follows when these structures are exposed to detergents. In mitochondria, such phenomena have been observed and subjected to thorough study. In the present case, it is not possible to delineate the exact mechanism of the inhibition. More extensive data are needed for a complete explanation. One possibility could be that the substances mentioned bring about a disturbance in the spatial arrangement of the enzymes involved, and thus a decreased reaction-rate.

Conclusion

The study of phenomena related to the active, energy-consuming transport of molecules across cellular membranes has generally been possible only with preparations consisting essentially of intact cells. Such a situation is not ideal for a detailed biochemical analysis of the phenomenon. A number of extremely important cell functions are intimately connected with the active transport of various substances across the cell membrane. The secretory mechanisms of glands, the re-absorption of a great number of substances in kidney tubuli, and the electrical activity of nerves and other conducting tissues may be mentioned. From the biochemical point of view all these phenomena are almost entirely unexplained. The possibility of studying phenomena related to the active transport of sodium ions through the nerve cell membrane by the use of a suspension of isolated microsomes from the brain has been indicated above. Such a technique may prove useful in the study of the mechanisms involved in these processes.

CODING RATIO FOR THE RIBONUCLEIC ACID VIRUSES

By C. R. WOESE

General Electric Research Laboratory, Schenectady, New York

IT is a generally held view that nucleic acids carry the information necessary to specify the primary structure of proteins. As there are only four kinds of nucleotides in any one kind of nucleic acid and 18–20 kinds of amino-acids in protein, it is reasonable that at least a triplet of nucleotides is required to specify a particular amino-acid[1]. Several hypotheses have been advanced to account for the coding of protein primary structure in terms of nucleotide triplets[2,3]. A nucleotide triplet is presumed to be composed of adjacent nucleotides along a single polynucleotide chain (at least in the case of ribonucleic acid (RNA)).

Yčas, however, has recently advanced the interesting hypothesis that, in the case of virus RNA, not a triplet of nucleotides along the RNA chain but rather a single nucleotide corresponds to any given amino-acid. This hypothesis necessitates that the 18–20 amino-acids fall into four groups, one group for each kind of nucleotide[4]. Further, in order to distinguish among amino-acids within any one group, it is necessary to invoke a second source of information not contained in the RNA of the virus (at least in the above sense of coding). This hypothesis, if true, should presumably hold for more than RNA viruses. We might expect to find a coding ratio, n (defined as the number of nucleotides specifying an amino-acid) of unity for most RNA molecules. It is the purpose of the present article to discuss Yčas's novel and important suggestion.

First, let us briefly outline Yčas's approach in arriving at the conclusion that n is unity. This approach is to compare both the protein and nucleic acid composition of six well-characterized RNA viruses, southern bean mosaic (SBM), tomato bushy stunt (TBS), cucumber (CV), tobacco mosaic (TMV), turnip yellow (TY) and polio (PV). To do this the quantity $1/2\Sigma|D_a|$ is defined as "one-half the sum of the absolute values of the differences between the quantities, expressed as moles per cent, of corresponding amino-acids in two proteins". An analogous expression, $1/2\Sigma|D_n|$, is defined for the two corresponding virus RNA's. The ratio of these two, $1/2\Sigma|D_n| \;/\; 1/2\Sigma|D_a|$, is designated r. This and the coding radio, n, are considered for the case of 'non-overlapping' codes only. The author then suggests that in general $r \leqslant 1/n$. However, this conclusion rests on several assumptions, mentioned below.

By comparing the composition of each of the RNA viruses in turn to that of turnip yellow (which has the most extreme compositional differences of all six viruses), Yčas finds the ratio r to be 0·90, SBM; 0·75, TBS; 0·66, CV; 0·83, TMV; and 1·09, PV. Two of these figures, at least, are indistinguishable from unity, and all are greater than 0·6. These high values of r are taken to mean, then, that the coding radio, n, cannot be greater than unity itself, as $r \leqslant 1/n$. Yčas shows it is possible to assign the individual amino-acids to four groups such that for all viruses the sum of the mole fractions of the amino-acids in any group is equal to the mole fraction of a particular nucleotide in the corresponding RNA, in keeping with a coding ratio $n = 1$. The nucleotide groupings are these: adenylate – glutamic acid (glutamine), glycine, leucine, phenylalanine and tryptophan; cytidylate – cysteine, lysine, methionine, proline and threonine; guanylate – alanine, arginine, tyrosine and valine; uridylate – aspartic acid (asparagine), *iso*leucine, histidine and serine. Unknown, X, factors not carried on the RNA distinguish among members of the same group.

Assuming a coding ratio $n = 1$, let us see what effect transformation of one nucleotide into another, or one group of nucleotides into another, has on the ratio r. For this purpose define the nucleotides as

A, C, G and U, and the corresponding amino-acids as $a_1, a_2, \ldots, c_1, c_2, \ldots, \ldots$ There are in all twelve possible kinds of single transformations among nucleotides, when transforming (formally) the composition of one virus into that of another. These are symbolized by the diagram:

$$\begin{tikzcd}
& U \arrow[dl, shift left] \arrow[dr, shift left] \arrow[dd, shift left] & \\
A \arrow[ur, shift left] \arrow[rr, shift left] \arrow[dr, shift left] & & C \arrow[ul, shift left] \arrow[ll, shift left] \arrow[dl, shift left] \\
& G \arrow[ul, shift left] \arrow[ur, shift left] \arrow[uu, shift left] &
\end{tikzcd}$$

All these taken singly have an r value of unity. However, we can distinguish several types of pairs of nucleotide transformations, some of the overall r value of which is less than unity. For example,

$$\begin{matrix} A \to C \\ a_1 \to c_1 \end{matrix} \text{ and } \begin{matrix} C \to A \\ c_1 \to a_1 \end{matrix} \tag{1}$$

this cannot be distinguished from no transformation at all, so all such pairs are eliminated from the diagram as contributing nothing:

$$\begin{matrix} A \to C \\ a_1 \to c_1 \end{matrix} \text{ and } \begin{matrix} C \to A \\ c_2 \to a_2 \end{matrix} \tag{2}$$

this has an overall value $r = 0$;

$$\begin{matrix} A \to G \\ a_1 \to g_1 \end{matrix} \text{ and } \begin{matrix} G \to C \\ g_1 \to c_1 \end{matrix} \tag{3}$$

this is identical with $\begin{matrix} A \to C \\ a_1 \to c_1 \end{matrix}$, and $r = 1$;

$$\begin{matrix} A \to G \\ a_1 \to g_1 \end{matrix} \text{ and } \begin{matrix} G \to C \\ g_2 \to c_2 \end{matrix} \tag{4}$$

this has an overall value $r = 0{\cdot}5$.

Therefore, we see that if we are to maintain the overall r value of unity, we have to eliminate all nucleotide transformations (or pairs, etc., of transformations) which have $r < 1$ associated. Consequently, for a case, say, where two viruses, X and Y, differ in RNA composition by $C_x > C_y$ and A_x, G_x, $U_x < A_y$, G_y, U_y respectively (as is the case for TY and PV), the above diagram for possible nucleotide transformation would be restricted to $\begin{tikzcd} U \arrow[dr] & \\ A \arrow[r] & C \\ G \arrow[ur] & \end{tikzcd}$ in order that r be unity.

In addition to these considerations we must determine what effect transformations in the unknown, X, factors have on the ratio r. If such a transformation occurred, it could cause the following compositional change: $\begin{matrix} A(X) \to A(X') \\ a_1 \to a_2 \end{matrix}$, with an associated r value of 0. However, when X factor transformations can be coupled (formally) to nucleotide transformations as in the following example, the resulting r value for the two taken together is unity.

$$\begin{matrix} A(X) \to A(X') \\ a_1 \to a_2 \end{matrix} \text{ and } \begin{matrix} A \to C \\ a_2 \to c_2 \end{matrix} \text{ or } \begin{matrix} G \to A \\ g_1 \to a_1 \end{matrix}$$

The entire argument above, while it does not militate against the hypothesis of Yčas, does point out that there is no *a priori* reason to suspect that, given a coding ratio $n = 1$, the ratio r should be also unity. In fact, one would *a priori* suspect that r would be less than unity. All these considerations make me feel that the hypothesis of a coding ratio $n = 1$ is somewhat artificial, and that the experimental fact $r \infty 1$ is best explained on some other basis.

Table 1. AMINO-ACID AND NUCLEOTIDE COMPOSITION OF RNA VIRUSES

The data on composition of the viruses is that compiled by Yčas (ref. 4); amino-acid abbreviations are those of the same reference

* Without regard to order within a triplet.

For this reason I have re-investigated Yčas's assertion that coding ratios greater than unity are necessarily ruled out. His proof that $r \leqslant 1/n$ is contingent on the condition that many different kinds of amino-acids contribute to $\Sigma|D_a|$. Also, the exact nature of the code will affect r somewhat. However, in order to disprove the contention that n must be unity for the RNA viruses, it is merely necessary to show that some code for which $n > 1$ is compatible with the published data. That such is the case is shown in Table 1. This triplet code was devised by the inelegant process of trial and error. There is no reason for believing that it is unique, or that one which fits the data better might not be devised. Although the agreement with experiment is not so good as with the singlet code, the code does accomplish the one end for which it was designed: to show that the composition of the six viruses is not incompatible with at least one triplet code. This relieves us of the necessity of having to assume a coding ratio of $n = 1$ and the concomitant postulate of other unidentified carriers of information not residing within the virus nucleic acid.

It will be noticed that the present code is neither a commaless code (that is, it contains UUU and CCC) nor is it a code according to Gamow's formulation (that is, order within the triplet is important). The present triplet code is examined in more detail elsewhere.

I wish to thank Dr. Martynas Yčas for stimulating my interest and for discussing his hypothesis with me.

A SEQUENTIAL GROWTH RESPONSE TO GIBBERELLIC ACID, KINETIN AND INDOLYL-3-ACETIC ACID IN THE WHEAT COLEOPTILE (*TRITICUM VULGARE* L.)

By Dr. S. T. C. WRIGHT

Agricultural Research Council Unit on Plant-Growth Substances and Systemic Fungicides,
Wye College, University of London

IN earlier work[1] the two fundamental growth processes of cell division and cell expansion in relation to the growth and differentiation of the wheat coleoptile were investigated. This was done by estimating the cell number, using the hæmocytometer method of Brown and Rickless[2], and cell volume by dividing the fresh weight of the coleoptile by the respective cell number, making the usual assumption that cell volume is equivalent to the fresh weight of the cell. In these experiments the wheat (var. Eclipse) was grown at 23° C. in darkness. Whole coleoptiles were excised from young seedlings and the enclosed primary leaves teased out under a dissecting microscope. The results are presented in Table 1.

Table 1

Age of coleoptiles (hr.)	Fresh weight per coleoptile (mgm.) (± 2 *s.e.*)	Cell No. per coleoptile × 10^{-3} (± 2 *s.e.*)	Average cell volume × 10^{9} (cm.^{3}) (± 2 *s.e.*)

144	75·9 ± 10·6		50·9 ± 7·20

From these results the rate of increase in cell volume, cell number and coleoptile fresh weight over 6-hr. periods was calculated and the histograms are depicted in Fig. 1 *a–c*. The histogram representing the average rate of increase in cell volume (Fig. 1*a*) is rather misleading since the method of estimation of cell volume incorporates the negative growth-rate of cells in the process of division (that is, the volume of a cell is halved approximately when it divides), and therefore tends to under-estimate the growth-rate when cell division is taking place. A much better estimate of the average rate of increase in cell volume is given by the histogram of fresh weight for the whole coleoptile, ignoring cell number altogether. Reference to this histogram (Fig. 1c) shows that cell expansion in the coleoptile can be divided into two phases: an initial phase in which the rate of cell expansion increases rapidly and then falls abruptly, and a second slower, almost linear, phase of cell expansion which continues for 30 hr. before declining. A very similar histogram showing these two phases of cell expansion has also been obtained for another variety of wheat (King II).

Since it has been shown that gibberellic acid and kinetin elicit greater elongation in young tissues than in the more mature[3], it was postulated that the early rapid growth-phase in the coleoptile might be regulated by endogenous gibberellin or kinin-like substances, whereas the second, slower, linear phase of cell expansion might be invoked by endogenous auxins.

As a means of testing this hypothesis, the reaction of coleoptiles of different ages to exogenous solutions of gibberellic acid, kinetin and indolyl-3-acetic acid was investigated. This experiment was carried out in two stages. First, dosage-response curves were determined for a series of coleoptile ages for each growth regulator (Fig. 2). The wheat was grown under the conditions already described here. Four replicates of five coleoptiles (with their enclosed primary leaves) were used for each treatment. Each batch of five coleoptiles was placed in a test-tube (3 in. × ½ in.) containing 0·6 ml. of the solution to be tested, and after sealing with 'Parafilm' the tubes were transferred to a klinostat for 24 hr. at 26° C. in red light. The coleoptiles were measured before and after treatment.

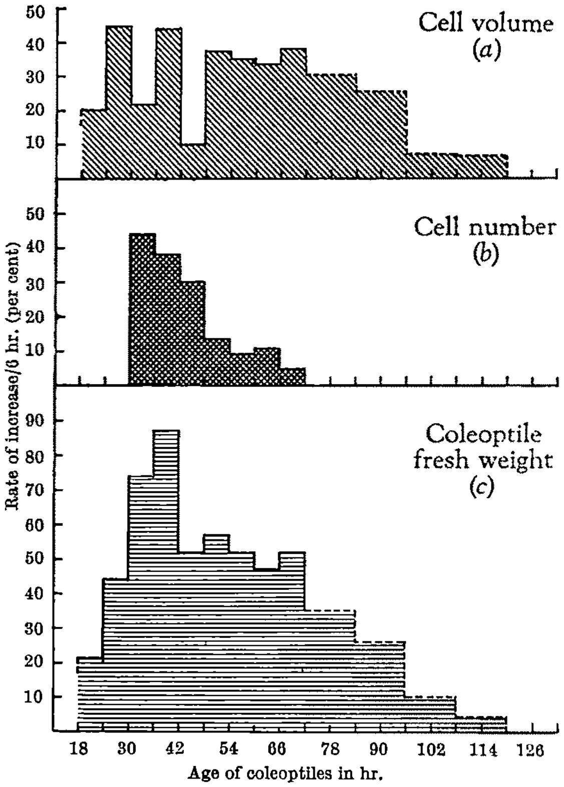

Fig. 1. Histograms illustrating the percentage rates of increase during 6-hr. periods of (*a*) the average cell volume, (*b*) cell number, and (*c*) the coleoptile fresh weight, during the growth and differentiation of the wheat coleoptile

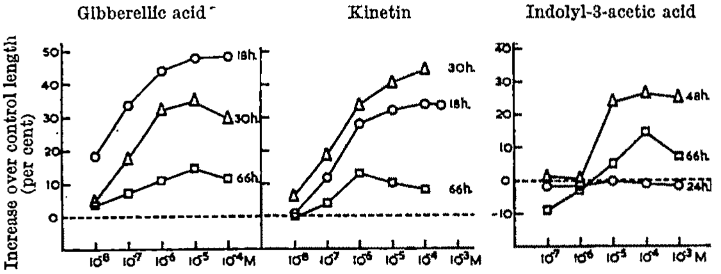

Fig. 2. Dosage-response curves for gibberellic acid, kinetin and indolyl-3-acetic acid given by coleoptiles of different ages (*h* = hours from sowing)

By referring to the dosage-response curves, it was possible to note the concentrations giving the optimal growth-response over a range of coleoptile ages for each growth regulator (Fig. 2). Thus a 10^{-5} *M* solution of gibberellic acid invoked an optimal response for coleoptiles at 18, 30 and 66 hr. after sowing and was therefore chosen to represent gibberellic acid in the final stage of the experiment. Similarly, a 10^{-4} *M* solution was selected for both kinetin and indolyl-3-acetic acid. (There was no significant difference between the growth response of 66-hr. coleoptiles to 10^{-4} *M* and 10^{-6} *M* concentrations of kinetin.)

By using only one concentration for each growth regulator, it was possible to determine the growth response of coleoptiles at 18, 30, 42, 54, 66 and 78 hr. after sowing in one large-scale experiment and thereby eliminate any inter-experimental variation in coleoptile sensitivity. These results are shown in Fig. 3 with twice *S.E.* limits. The wheat coleoptile is most sensitive to exogenously supplied gibberellic acid at or before 18 hr. after sowing, and during growth and development the response declines until at 78 hr. it is only 2 per cent above controls. Kinetin, on the other hand, gives a maximal growth stimulation at 30 hr. after sowing. Lastly, coleoptiles do not give a positive response to indolyl-3-acetic acid until 30–42 hr. after sowing and are most sensitive at about 54 hr. Thus under these experimental conditions it was established that there is a sequential growth response of the coleoptile to the three growth regulators, first to gibberellic acid, then to kinetin and finally to indolyl-3-acetic acid. This result has been obtained on three separate occasions.

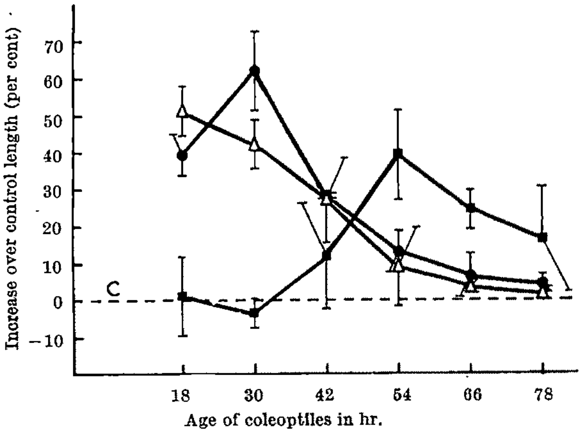

Fig. 3. Sequential growth response of the wheat coleoptile to exogenous solutions of gibberellic acid, kinetin and indolyl-3-acetic acid. The vertical lines indicate the 2 *S.E.* limits. △, Gibberellic acid, 10^{-5} *M*; ●, kinetin, 10^{-4} *M*; ■, indolyl-3-acetic acid, 10^{-4} *M*

The greatest sensitivity to gibberellic acid can be correlated with the period of cell expansion that precedes division (compare Fig. 1 *b* and *c* with Fig. 3), whereas kinetin elicits the greatest response from coleoptiles in which many of the cells are about to divide (compare Fig. 1*b* with Fig. 3). These results suggest that these two growth regulators have separate roles to take in the growth process. Nevertheless, their concerted efforts could account for the initial rapid cell expansion phase as postulated in the hypothesis above. This dual-action concept was supported by: (1) an examination of stained sections of 18-hr. coleoptiles after treatment with gibberellic acid and with kinetin for 24 hr., which showed that the growth response for both substances was due to cell expansion only; and (2) by a correlation between the rapidly falling growth-rate occurring at 42–48 hr. with a corresponding fall in sensitivity of the coleoptile to gibberellic acid, and kinetin (compare Fig. 1c with Fig. 3). Although indolyl-3-acetic acid did not induce cell expansion in very young coleoptiles, this does not mean that it is not required for other physiological functions and, indeed, tissue culture studies suggest that both it and kinetin are necessary for cell division[4,5].

One cannot be certain from these results that the natural growth of the coleoptile is controlled in this way by endogenous growth regulators, but evidence is accumulating in the literature for the presence of gibberellin[6,7] or kinin-like substances[5] in young tissues, and the occurrence of indolyl-3-acetic acid in oat coleoptiles (20–30 mm. long) has been claimed by several workers[8,9].

Perhaps the most plausible explanation of the sequential growth-response is that there is an optimal concentration ratio of these three types of growth regulators (and possibly others) for each stage of cell growth. One might postulate that, in a predetermined order, one concentration ratio induces the early type of cell expansion, another invokes cell division and another the final cell expansion phase. Such a coding system might operate by its action on enzyme activation or synthesis at each stage of growth[10,11]. Thus it is conceivable that cellular growth and differentiation proceed as the result of growth regulators, individually[11], or in certain concentration ratios[4,10] leading to the activation of a particular enzyme spectrum. These enzymes, by their action on their specific substrates, could in turn bring about a gradual change in the concentration pattern of the growth regulators in the cell and thereby initiate the activation of a different enzyme spectrum and so on, until differentiation is complete.

I thank Prof. R. L. Wain for his interest and encouragement in this work. The results will be reported in detail elsewhere.

EFFECTS OF QUALITY OF LIGHT ON DEVELOPMENT OF ROOTS ON DWARF BEAN HYPOCOTYLS IN PRESENCE AND ABSENCE OF BORON

By Dr. E. C. HUMPHRIES
Rothamsted Experimental Station, Harpenden, Herts.

SINCE Warington[1] discovered that boron is an element essential for growth of *Vicia faba* and demonstrated[2] that meristems cannot develop normally without it, many theories about its role have been advanced but none is entirely satisfactory. The latest theories are by Gauch and Dugger[3], who consider that boron plays a part in the transport of carbohydrate, and by Winfield[4] and Whittington[5], who postulate that it is concerned in the formation of pectic substances in the cell wall. The results described here suggest that boron metabolism is influenced by the quality of light received by the plant. Hemberg[6] found that cut plants of *Phaseolus vulgaris* with two developed leaves formed roots on their hypocotyls only when the solution bathing them contained boron. This was afterwards confirmed by Gorter[7], and Weiser[8] obtained similar results with *Clematis* cuttings. My work followed a chance observation that the extent to which roots developed on hypocotyls of cut bean plants without boron depended on whether the light supplied was from fluorescent tubes only or these tubes plus incandescent lamps.

Plants of dwarf bean (*Phaseolus vulgaris*; var. Canadian Wonder) were grown from surface-sterilized, weight-graded seed sown in John Innes compost; the plants were in cabinets at a constant ambient temperature of 20° C. and light was provided either by fluorescent tubes alone (3,500° K., white, reflector) or these were supplemented with incandescent tubes ('architectural' strip lights), when the ratio of watts consumed by the fluorescent to incandescent light was 8 : 3. Humidity was not controlled, and the plants were given a daily photoperiod of 8 or 16 hr. The light intensity at the leaf surface was 1,400 ft.-candles.

When the first pair of leaves was fully expanded and the next leaf just beginning to unfold, the hypocotyls were severed 4 cm. below the cotyledonary node, sterilized by agitation for a few seconds in hydrogen peroxide ('10 vol.'), washed in distilled water and then placed in 100 ml. conical flasks covered with black paper. The flasks contained 100 ml. of half-strength Hoagland solution + 1 mgm./l. iron as tartrate, made up in glass-distilled water further purified by passage through a mixed anion and cation exchange resin and which was stored in polythene containers. The solution in half the flasks also included 10 μgm. of boron as boric acid, because preliminary experiments showed 0·1 mgm./l. to be optimal for stimulating root growth. The flasks were of boro-silicate glass and may have supplied some boron to the plants, but, if so, they had little effect compared to added boron. The cut plants with no additional boron are referred to as the low-boron and the others as high-boron plants. While the plants were growing in the compost, before the hypocotyls were cut, they showed no signs of boron deficiency, but when the hypocotyls were severed and placed in solutions without added boron the plants quickly showed symptoms of boron deficiency.

After severing the hypocotyls, half the plants previously grown in fluorescent light were given incandescent light in addition, while the other half was maintained in fluorescent light alone. Similarly, half the plants previously given both fluorescent and incandescent light were maintained in this condition and the other half transferred to fluorescent light alone. Thus, there were four light treatments, and in each the same photoperiod was maintained both before and after severing the hypocotyl. The cut hypocotyls were placed in the different culture solutions topped up daily with the purified distilled water. After 14 days, the roots emerging from the hypocotyls were counted as well as the number of 'root initials'—the number of protrusions at the surface of the hypocotyl which failed to develop further. The total fresh weight of roots of each plant was also determined as well as the dry weight of the 4-cm. length of hypocotyl. The number of roots formed is taken to indicate the number of meristems that developed, whereas fresh weight measures the growth of the meristems. The length of hypocotyl occupied by roots was found to be constant in all treatments. A total of 136 plants was used in the 16-hr. photoperiod and 160 in the 8-hr. photoperiod.

All plants received a treatment with fluorescent light (−). Treatment in which plants received incandescent light before excision is called X, and after Y; thus, a combination of $X + Y$ indicates that the plants received incandescent light throughout the experiment. There was no effect of quality of light in the 8-hr. photoperiod and the following remarks refer mainly to results from a 16-hr. photoperiod. Table 1 shows that incandescent light given before or after excision of the hypocotyl decreased root number and total root fresh weight of low-boron plants. By contrast, the light treatments did not affect high-boron plants. As many roots were formed on high-boron plants in an 8-hr. photoperiod as in a 16-hr. period, but the shorter day-length decreased the number of roots formed by low-boron plants. In addition to affecting root formation, boron alters the response to the type of light. Although estimates of root initials are subjective and those in Table 1 are only approximate, they show that root initials were few with treatments that formed roots freely, and many with others. Thus, root initials usually varied inversely with the number of roots, but roots and root initials together totalled many more with high-boron than low-boron plants. Root fresh weight varied with root number, with the additional effect

(−), fluorescent light. *X*, incandescent light before excision. *Y*, incandescent light after excision.

that incandescent light after excision decreased fresh weight of high-boron plants also. Incandescent light, however, affected low-boron plants more, for without it plants had similar root fresh weights whether or not they were given boron (350 and 335 mgm.). In other words, boron deficiency restricts root growth only with incandescent light. Although boron increased the number of roots, the low-boron plants had greater fresh weight per root than high-boron plants in both photoperiods (Table 1), perhaps because the fewer meristems of low-boron plants suffered less competition for products of photosynthesis. Similarly, the primary leaves of whole bean plants grown in water culture without boron were larger than those grown with boron (boron-deficient plants had a mean midrib length of 70 mm. and those with boron 65 mm., based on a sample of 360 plants), possibly because nutrients which would normally go to the growing point are diverted to the leaves when the growing point aborts in boron-deficient conditions[9].

The growth of the hypocotyl was decreased in low-boron plants by incandescent light given before excision but not after. By contrast, incandescent light decreased hypocotyl dry weight in high-boron plants after excision. Thus, boron had little effect on root formation in plants illuminated only with fluorescent light; but with incandescent light, root formation depended on added boron.

The leaves were fully illuminated but little radiation reached the submerged hypocotyl, because covers on the flasks excluded lateral illumination and direct illumination was confined to the narrow opening of the flask partly obscured by the primary leaves. The action of light on root formation can therefore be assumed to be indirect. Incandescent light inhibited root formation only in the 16-hr. photoperiod, perhaps only because too few roots formed on low-boron plants in an 8-hr. photoperiod to show differences. Any inhibition presumably arises in the leaf and persists after the hypocotyl is severed. How inhibition by incandescent light is linked with boron deficiency is uncertain, but there are several possibilities. For example, boron may protect a root-promoting substance from destruction by incandescent light or perhaps incandescent light affects mobility of boron in the plant.

The site where the light stimulus interacts with boron depends on the mobility of boron in the cut plants. Published evidence that boron is rather immobile is confirmed in my experiments. The soil contained enough boron for growth of the plants, but as soon as the hypocotyl was severed, more was necessary for meristems to develop in both root and shoot, indicating that boron already in the plant could not serve for this. Scholz[10], in experiments using single tobacco leaves with a divided root system, found that boron was not transferred from roots supplied with boron to those without it, but accumulated in the leaf. He concluded that boron moves only in the direction from root to shoot, and Albert[11] came to a similar conclusion. When I treated leaves of boron-deficient plants with boron solution, boron was evidently translocated to the hypocotyl, because meristem development was stimulated, and in the experiments described above boron was transferred from the solution bathing the hypocotyl to the shoot, because apical meristem development continued in these plants. Evidently under these conditions boron is translocated either upwards or downwards, but perhaps this applies only to inorganic boron, and conditions in intact plants may be different. The evidence does not show where boron and the light stimulus interact.

In some respects boron resembles indoleacetic acid in stimulating root formation on hypocotyls; but indoleacetic acid and boron differ in that the former is necessary to stimulate meristem activity, whereas, as Hemberg (*loc. cit.*) points out, the latter does not affect the formation but only the growth of roots; hypocotyls grown in media deficient in boron develop wart-like elevations (called 'root initials' here), which do not develop into roots. It seems unlikely, therefore, that the present phenomenon is concerned with indoleacetic acid metabolism. My experiment suggests a connexion between radiation in the red or far-red part of the spectrum that inhibits root-growth when boron is a limiting factor, but this has yet to be investigated fully. That light and boron metabolism may be connected is suggested by other work. Symptoms of boron deficiency develop sooner and more severely in long than short days (Gauch and Dugger[3]) and Stegemann[12] concluded that the action of radiation is regulated by boron. Albert[11] suggested that some factor, other than carbohydrate, present in the top of the plant, is affected by light and may influence the response of tomato plants to boron deficiency. Skok[13] found that sunflower leaves were more radiosensitive with than without boron.

AN ESTIMATE OF THE AROMATICITY OF THE ORGANIC MATTER OF A PODZOL SOIL

By Dr. J. R. WRIGHT and Dr. M. SCHNITZER

Soil Research Institute, Department of Agriculture, Ottawa, Canada

IN our work on the chemical structure of the organic matter of the A_0 and B_h horizons of a podzol we were interested in a practical method for estimating the aromaticity of these materials. Such a method has recently been described by Mazumdar *et al.*[1] and Chakrabartty *et al.*[2] for determining the aromaticity of lignite, bituminous and higher-rank coals. Since soil organic matter resembles lignites and brown coals in many respects, we thought application of this procedure to such material might yield valuable information with regard to its aromaticity. As a check on our technique, we included a sample of lignite in this investigation because values for the aromaticity of this material are available in the literature.

According to Mazumdar *et al.*[1], heating of coal in air at 170° C. for approximately 500 hr. causes the complete oxidation of the 'disordered' (aliphatic and alicyclic) carbon while leaving the aromatic network intact. The oxidation of the 'disordered' carbon results in the formation of oxygen-containing functional groups, mainly carboxyls. Therefore, the only aliphatic carbon and hydrogen in the final oxidized product is that in carboxyl groups. Thus the total carbon and hydrogen in the final oxidized product, corrected for the carboxylic carbon and hydrogen, gives the total aromatic carbon and hydrogen present in the original material. In addition, in the case of hydrogen, it is necessary to correct for hydrogen replaced by quinone groups[2].

The soil samples and methods of extraction of organic matter were the same as those described previously[3] except that all extractions were made under nitrogen and the extracts were dried under reduced pressure at room temperature. The lignite sample originated from the Souris, Manitoba, area. Carboxyl groups were determined by reaction with calcium acetate[4], phenolic hydroxyls by reaction with barium hydroxide under nitrogen and correcting for carboxyls[5]. Carbonyls were determined by the method of Fritz *et al.*[6] and ultimate analyses by dry combustion.

1-gm. samples, spread in thin layers in aluminium dishes, were heated in an oven at 170° C. for various lengths of time up to and including 600 hr. A current of air was passed through the oven at a constant rate. Samples were withdrawn every 100 hr., weighed and analysed for functional groups and ultimate composition. Under these heating conditions, Mazumdar and Lahiri[7] reported that lignite and higher-rank coals reached constant weight after 300–400 hr. With our samples the A_0 material reached constant weight at approximately 500 hr. while the lignite and B_h preparation still continued to lose weight although the rate of loss was low (1·8 and 1·6 per cent in the 500–600 hr. period). In view of these findings we adopted a heating period of 600 hr. for all samples.

All results shown in Tables 1–4 under "after oxidation" refer to 600 hr. of heating.

Heating caused an increase in the carbon contents of the A_0 and B_h materials and a decrease in that of lignite (Table 1). All materials reached a constant carbon content between 200 and 300 hr. Most of the hydrogen was lost during the first 100 hr. This is in agreement with the findings of Chakrabartty *et al.*[8] that dehydrogenation appears to be the main reaction in the initial stages of coal oxidation. After 600 hr. of heating, 100, 93 and 87 per cent of the original nitrogen still remained in the oxidized residues of the lignite, B_h and A_0 materials respectively.

The carboxyl contents of the original lignite, A_0 and B_h materials were 2·0, 6·7 and 40·9 per cent respectively. In the case of lignite the carboxyl content increased to a constant value after about 400 hr. of oxidation. On the other hand, the carboxyl contents of the A_0 and B_h materials decreased during the initial stages of the oxidation. This was followed by a slight rise with constant values being obtained after 400 hr.

The values for carbon aromaticity (Table 2) represent aromatic carbon as a fraction of total carbon. The values in brackets represent aromatic carbon as a fraction of total carbon less carboxyl carbon. These values are shown in order to give an estimate of the aromaticity of the carbon skeleton. As shown in Table 2, the two values for lignite are identical because this material and higher-rank coals contain few or no carboxyl groups prior to oxidation in contrast to soil organic matter preparations. The value of 0·56 for the aromaticity of lignite agrees well with that reported by Chakrabartty *et al.*[2]. The hydrogen aromaticity, similar to the carbon aromaticity, was calculated on the basis of both total hydrogen and total hydrogen minus carboxyl hydrogen (Table 3). Hydrogen aromaticity of the lignite analysed by Chakrabartty *et al.*[2] was 0·29.

Infra-red spectra of the A_0 and B_h materials taken at various stages of the oxidation showed a gradual decrease and finally complete disappearance of the 2,920 and 2,850 cm.$^{-1}$ bands (aliphatic C—H). After 50 hr. of heating the infra-red spectra of the B_h material showed new bands at 1,840 and 1,775 cm.$^{-1}$ which, together with the band already present at

1,200 cm.$^{-1}$, indicated the probable formation of cyclic anhydrides[9]. Also, new bands appeared at 920 cm.$^{-1}$ (OH deformation vibrations of COOH) and at 740 cm.$^{-1}$ (polycyclic aromatic structures). All these bands increased in intensity with heating. From the infra-red spectra we estimated that not more than 10 per cent of the carboxyl groups of the B_h material had formed anhydrides. On this assumption the correction for H_{COOH} (Table 3) should be 10 per cent lower resulting in a correspondingly higher hydrogen aromaticity.

A carbon and hydrogen balance is shown in Table 4. Exclusive of the carboxylic carbon and hydrogen, the A_0 material contained more aliphatic and/or alicyclic carbon and hydrogen than the B_h preparation. This would indicate that the carbon skeleton of the B_h is more aromatic than that of the A_0 material. Similar conclusions were reached from oxidative degradation studies of these two materials[10].

LETTERS TO THE EDITORS

RADIOASTRONOMY

Secular Variation of the Flux Density of the Radio Source Cassiopeia A

Högbom and Shakeshaft[1] have recently presented evidence for a secular variation of the intensity of radio emission from the source Cassiopeia A. Their observations, made at a frequency of 81·5 Mc./s. over a period of 12 years, suggest that the flux density of Cassiopeia A relative to that of Cygnus A is decreasing at a rate of about 1 per cent per annum. This type of measurement may be sensitive to unknown systematic instrumental effects, and the importance of the result makes independent confirmation desirable.

Observations of the ratio of flux densities of Cassiopeia A and Cygnus A were begun at the National Radio Astronomy Observatory in 1959, in order to search for a possible change in intensity of Cassiopeia A. While these observations cover a period of only one year, they do, in conjunction with earlier observations at about the same frequency obtained at other observatories, provide some confirmation of the result of Högbom and Shakeshaft.

The available 1,400-Mc./s. observations of the ratio of Cassiopeia A to Cygnus A are given in Table 1. The Leyden[2], Bonn[3] and National Radio Astronomy Observatory[4] observations were made with antennae of about the same diameter, 82–85 ft., and were corrected for atmospheric extinction and receiver non-linearity. The Naval Research Laboratory observations[5] were made with a 50-ft. diameter antenna. The Leyden, Bonn and National Radio Astronomy Observatory observations all have small internal uncertainties. Systematic effects should also be small, as in each case the observational procedures were specifically selected to minimize them so far as possible. Although the Naval Research Laboratory measurements are of lower accuracy than the others they are of particular value because they are the earliest measurements of these sources at this frequency. Details of the equipments, observing techniques and reduction procedures used in the various measurements are given in the references cited.

Fig. 1 shows the 1,400-Mc./s. flux density ratios as a function of time. The solid line in Fig. 1 represents the change in Cassiopeia A/Cygnus A at 81·5 Mc./s., found by Högbom and Shakeshaft. The 1,400 Mc./s. observations suggest a secular change in reasonable agreement with that found at 81·5 Mc./s. The vertical displacement of the 1,400 Mc./s. and 81·5 Mc./s. ratios is due to the difference in spectra of the two sources.

Table 1

Date	Cas. A/Cyg. A	Frequency (Mc./s.)	Source
1954	1·8 ± 0·1	1,394	NRL
1956	1·63 ± 0·01	1,395	Leyden
1958	1·63	1,419	Bonn
1959	1·608 ± 0·003	1,400	NRAO
1960	1·592 ± 0·003	1,400	NRAO

NRAO, National Radio Astronomy Observatory.

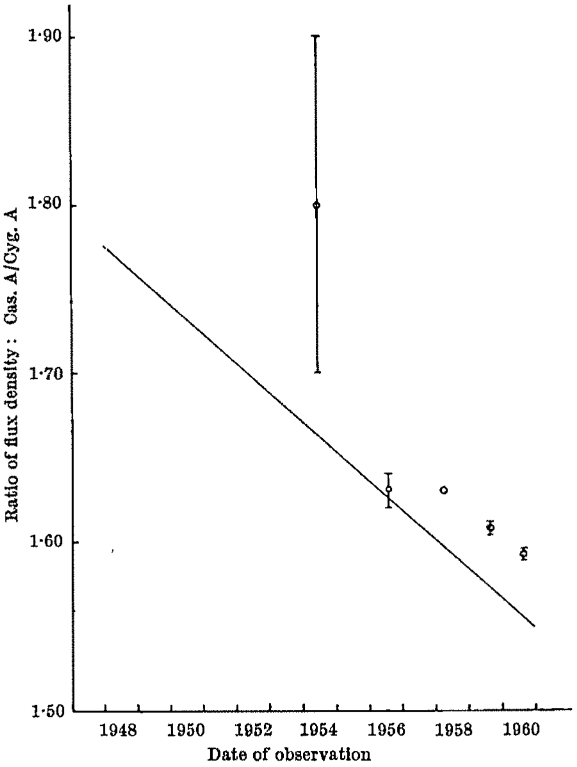

Fig. 1. Variation of the ratio of intensities of Cassiopeia A and Cygnus A as a function of time. Points with circles give measurements at a frequency of 1,400 Mc./s. Vertical lines show the published uncertainties in the measurements. No estimate of error was given for the 1958 measurement. The solid line is the variation of Cas.A/Cyg. A with time at 81·5 Mc./s., as found by Högbom and Shakeshaft (ref. 1)

The 1960 result, given in Table 1 and Fig. 1, is the mean of sixteen sets of observations made at one-week intervals in the period June 17–September 30, 1960. These observations were made with the same receiver and antenna, under as nearly identical conditions as possible. They have high relative accuracy and should be largely free of any systematic

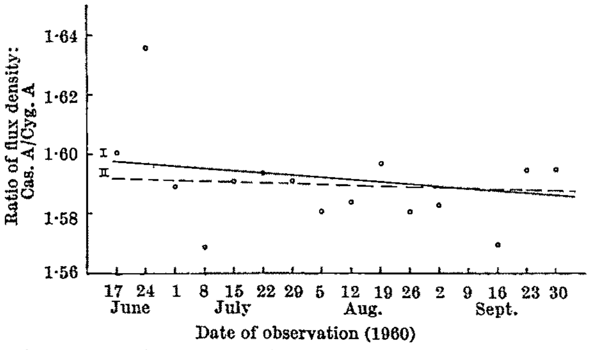

Fig. 2. Weekly measurements of Cas. A/Cyg. A at 1,400 Mc./s. The solid line (I) is the least squares straight line which best fits all the measurements. The dashed line (II) is the straight line which best fits the data if the four least accurate measurements are omitted

instrumental effects over the time-interval involved. The weekly measurements are shown in Fig. 2. Even over this short interval of time there is evidence of a systematic change in the ratio of Cassiopeia A to Cygnus A flux density. A least-squares solution for the best straight line representing all sixteen measurements gives a rate of decrease of 2·3 per cent per annum. This solution is shown by the solid line (I) in Fig. 2. A second solution was made omitting the four days on which the measurements deviated from the mean value by more than five standard errors. On two of these days (June 24 and July 8) the observer had noted on the records as they were obtained the probability of interference or marginal receiver performance. This solution, indicated by the dashed line (II) in Fig. 2, gives a rate of decrease of 0·9 per cent per annum. Both values are in good agreement with the results of Högbom and Shakeshaft.

The 1,400-Mc./s. measurements are not sufficiently accurate to determine the rate of decrease of intensity of Cassiopeia A with any reliability, so the question as to whether the rate of change is independent of frequency remains open.

We wish to thank Messrs. Högbom and Shakeshaft for a copy of their paper prior to its publication.

ASTROPHYSICS

Solar Wind and Terrestrial Oxygen

STEFANSSON[1] pointed out that nothing gained such universal acceptance as an error. This should make us all wary of unanimity, and it has led me to question persistently the general assumption that Earth's original atmosphere contained little or no oxygen and that the origins of life are to be sought exclusively among anaerobic reactions. The atmosphere now contains 230 gm. of oxygen per sq. cm. and perhaps twice that amount must have passed through the atmosphere at an early stage of Earth's development to account for ferric iron, sulphates, etc., in sediments. These quantities are so small that slightly different assumptions lead to radically different conclusions about the amount of oxygen at various times during the past 3×10^9 years. It has, nevertheless, been difficult to account satisfactorily for the oxygen and there is opposition to all the mechanisms proposed for its formation.

Those interested in the origins of life are therefore eager for comment on the suggestion[2] that Earth is gaining 1·5 tons of hydrogen a second from the solar wind, for this rate of accretion would provide all the hydrogen in the ocean in 3×10^9 years. If this is so, the oxygen in the ocean comes into the category of 'fossil oxygen' along with ferric iron. There are 230 kgm. of it per sq. cm., that is, 500 times the amount that has been causing trouble hitherto. If we exist, and have always existed, in this hydrogen hurricane, the problem of the origin of oxygen is more intractable than we thought.

RADIOPHYSICS

Variation in Height of Anisotropy and Random Drift Velocity of the Irregularities in the Ionosphere

HORIZONTAL ionospheric drift records taken by the spaced receiver method of Mitra[1] are used here to analyse the variation with height of anisotropy and random drift speed $(V_C)_v$ along the direction of steady drift of the irregularities.

Horizontal drift records were taken in rapid succession on several frequencies corresponding to different levels of reflexion on six days around the morning hours of 0900 I.S.T. The drift records were analysed by Phillips and Spencer's[2] correlation method to determine the steady and random drift velocities as well as the axial ratio r and orientation of the anisotropy ellipse. It is generally assumed that these values refer to the irregularities in the ionosphere. The true height of reflexion corresponding to each drift record was calculated, using Schmerling's[3] method, from an $h'(f)$ record taken at the same time.

Values of ν, the orientation of the major axis of the correlation ellipse in degrees east of north, showed no preferred direction, a feature which has also been reported earlier by Phillips and Spencer. However, on each occasion, the variation of ν with height in the ionosphere was found to be very systematic. A clockwise rotation of the major axis with increasing height is clearly evident on five of the six occasions. The gradient $\partial\nu/\partial h$ was found to vary between 54′ to 1° 42′ km.$^{-1}$ with an average of 1° 28′ km.$^{-1}$.

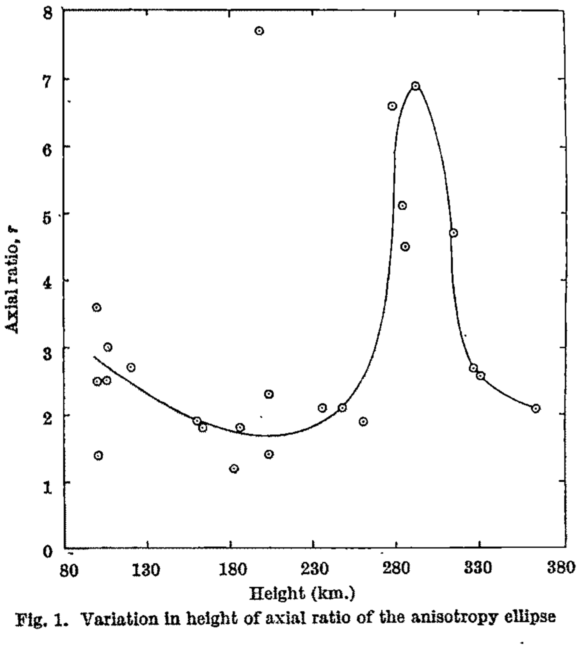

Fig. 1. Variation in height of axial ratio of the anisotropy ellipse

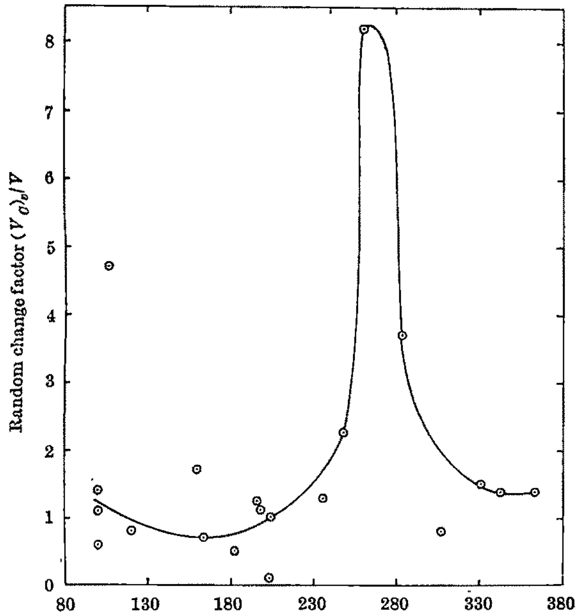

Fig. 2. Variation in height of the random change factor

The axial ratio r also showed a more or less systematic variation with height. In Fig. 1 is presented a plot of the axial ratio variation with height for all the six days. A smooth curve is drawn which passes through most of the observations. It can be seen that r decreases with height at first, slowly from about 100 km. to 190 km., then rises rapidly, reaching a maximum value of about seven at a height of about 290 km. Above this height, the value of r is found to decrease rapidly.

In Fig. 2 is presented a plot of the 'random change factor' $(V_C)_v/V$ versus height, where V is the steady drift velocity of the diffraction pattern on the ground. In this case, too, a smooth curve is drawn passing through most of the observations. This plot of $(V_C)_v/V$ is very similar to that in Fig. 1, except that the peak occurs at about 270 km. instead of at 290 km. It appears, from this work, that the ionospheric irregularities are highly elongated in regions where random motion predominates over the steady drift. It may be of interest here to point out that Yerg[4] also arrived at a similar conclusion when he stated that "large random changes are anisotropic and tend to cause the correlation pattern to be oriented along the magnetic field", although the latter trend is not clearly observed in our investigation. It is, thus, quite possible that, at this latitude, the irregularities responsible for the radio-star scintillations and spread F are located at about the level of 270–290 km. since $(V_C)_v/V$ and r are each a maximum in this region. However, it may be pointed out that the investigations were conducted by us only during daytime. Booker[5] suggested that radio-star scintillations cannot be explained in terms of turbulence if the height of irregularities causing the scintillation phenomena were taken to be located at 400 km. He concluded from certain theoretical considerations that a reasonable explanation can be offered for the scintillation phenomena if that height is about 200–300 km. The observation of large random drift velocities and also of intense spread F in the range of 200–300 km. at this station seems to lend support to this view.

A detailed paper on the investigations will be published elsewhere. We are indebted to the Council of Scientific and Industrial Research for supporting this investigation.

Irregularities in the E_s Layer of the Ionosphere

It has been shown from oblique incidence backscatter experiments that the equatorial type of sporadic E ionization (E_s) contains irregularities which are elongated in a north–south direction, that is, along the direction of the Earth's magnetic field[1]. On the other hand, observations made at high latitudes have shown that the auroral type of E_s layer contains irregularities which are elongated in an east–west direction, that is, perpendicular to the field[2]. The results in the second case were based on observations of the diffraction pattern produced on the ground by a reflected wave. No corresponding observations relating to the E_s layer in medium latitudes have been reported.

In the present communication, some observations made at Cambridge (lat. 52° N., long. 0° E.) are described. The method was based on measurements of the diffraction pattern produced by a wave reflected at vertical incidence. The transmitted pulses were 100–200 μs. in length, and the frequencies used were in the range 4·0–4·5 Mc./s. during the day, and 2·0–2·4 Mc./s. at night. The reflected waves were received on three crossed-loop aerials, arranged to accept the 'ordinary' circularly polarized component of the down-coming wave, and placed at the corners of a right-angled triangle having two equal sides 130 m. long in the north–south and east–west directions. The amplitudes of the received pulses were recorded using a pen-recorder, or on film if the fading became too fast to be recorded faithfully by the pen-recorder. Correlation analysis was applied to typical portions of the records for eighteen occasions between March 1959 and August 1960. The auto- and cross-correlation functions of the fading curves were calculated using an electronic digital computer, and the graphical method of Phillips and Spencer[3] was used in subsequent calculations to determine the properties of the diffraction pattern.

The results of the analysis show great variability in the scale of the irregularities in the diffraction pattern on the ground. For only nine of the eighteen occasions was it possible to determine a characteristic ellipse representing an average single irregularity in the pattern ; on the other occasions the irregularities were either very large (1 km. approximately) or very small (80 m. approximately) and their scale could only be estimated very roughly.

While it is not possible in general to determine the size of irregularities in the ionosphere simply from measurements of amplitude in the diffraction pattern on the ground[4], the axial ratio and orientation of the characteristic ellipse of the diffraction pattern do give a measure of the elongation and orientation of the irregularities in the ionosphere. When the characteristic ellipse could be found, it was not usually very elongated; on only three of the nine occasions was the axial ratio greater than 2·0, and there was no evidence of any preferred direction of elongation. This is in contrast with the systematic elongation found at high and low latitudes.

On all the occasions when the fading of waves reflected from the E_s layer was observed at Cambridge, E_s was also found on ionograms obtained at Slough, 90 km. to the south-south-west. There was, however, no apparent association between the scale of the irregularities in the diffraction pattern at Cambridge and the type of E_s (c, f, h or l) as determined by its appearance on the Slough ionogram[5]. There was also no association between the scale of the pattern and the magnetic K-index (K was in the range of 0–4 for the occasions observed).

This work forms part of a programme of research on ionospheric irregularities supported by a grant from the Department of Scientific and Industrial Research. I was in receipt of a maintenance grant from the same Department. Thanks are due to the Director of the Mathematical Laboratory, University of Cambridge, for permission to use the computer *Edsac* 2.

108–216 Mc./s. Radio Signals from Satellites below the Horizon

Smyth Research Associates have been conducting an experimental programme on low-angle refraction of radio waves penetrating the atmosphere.

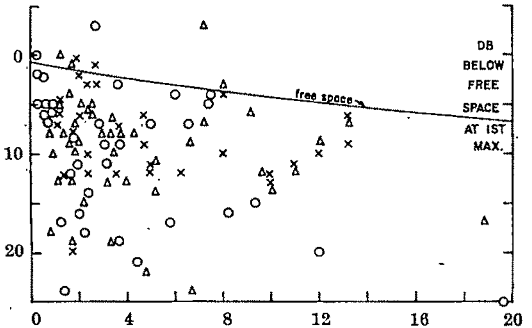

Fig. 1. Precursor signal-levels. ○, 108 Mc./s.; ×, 162 Mc./s.; △, 211 Mc./s.

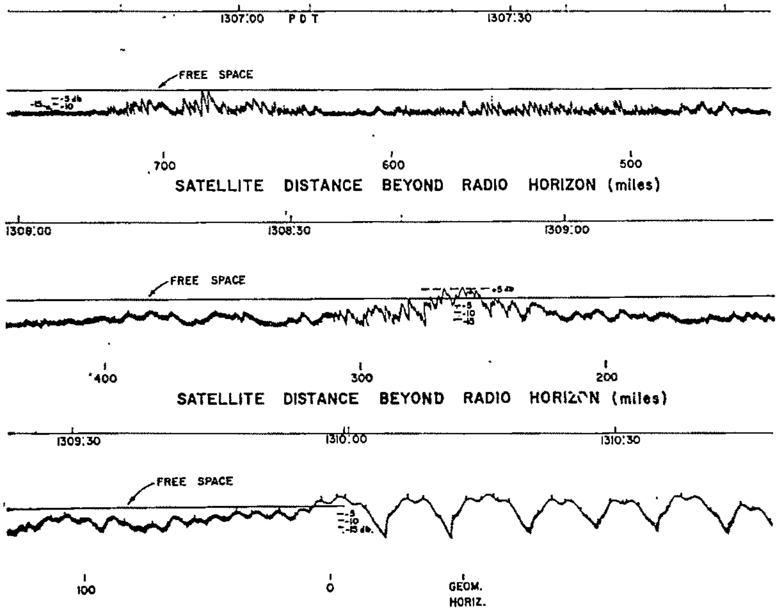

Fig. 2. Satellite precursor signals. Tiros I, 108 Mc./s. June 13, 1960

Satellite transmitters at 108, 162, and 216 Mc./s. have been used as signal sources in these studies. During the course of the measurements (June, July and August 1960) it was found that, on the majority of passes, signals were received while the satellite was well beyond the radio horizon. Out of a total of 49 cases when such 'precursor' signals were sought, only 14 failed to yield signals for at least one minute beyond the radio horizon.

In two cases, signals were first received when the satellite was 1,900–1,950 miles beyond the radio horizon point at orbit height. On these passes the satellite was roughly twice as far away as the distance to the horizon. The signal strength on these occasions was 11 db. below the free space-level on 216 Mc./s. and 18 db. below the free space-level on 108 Mc./s. As can be seen in Fig. 1, there appears to be no distinct dependence of received signal strength on frequency. Even simultaneous data on 162 and 216 Mc./s. show no consistent dependence on frequency.

The combination of low attenuation and no frequency-dependence suggests a tropospheric ducting mechanism. Correlation of local radiosonde data with signal strength and maximum path-length supports this view. The duct thickness and intensity in all cases when signals were observed exceeded the trapping requirements for frequencies greater than 100 Mc./s.

Fig. 2 shows the data record for one of these cases, together with a scale of the great circle distance of the satellite below the radio horizon. The record was taken at the Smyth Research Associates Point Buchon field site on the coast-line near San Luis Obispo, California, with a sea-interferometer system, giving rise to the pattern of maxima and minima above the horizon. Relatively minor tumbling nulls can also be seen superimposed on the interferometer trace.

A Transatlantic Communication Experiment via *Echo* I Satellite

THE article in *Nature* of January 28, p. 268, by Carru, Gendrin and Reyssat, described the reception by the Centre National d'Etude des Télécommunications of 960-Mc./s. signals reflected from the *Echo* I satellite during pass 70.

The signals originated at the Bell Telephone Laboratories' station in Holmdel, New Jersey, U.S.A. The transmitter frequency was measured just before pass 70 and found to be 960·045 Mc./s., which is in good agreement with the value of 960·045053 Mc./s. calculated by Carru *et al.* during reception some 20 min. later.

The 60-ft. diameter transmitting antenna used at Holmdel has a gain of 43·1 ± 0·1 db. instead of the value of 44 db. assumed by Carru *et al.* Transmitter power at the time of reception was 7·5 kW. and was further reduced by the 0·5 db. antenna-transmission line loss to 6·7 kW., which is 0·8 db. less than that assumed by Carru *et al.* Inspection of pointing records for the reception period shows that the Holmdel antenna was aimed to within 0·2° of the satellite, which would add an additional loss of no more than 0·1 db. These factors predict a smaller value for received signal by 1·8 db.; on the other hand, there is no justification for the assumption that the cross-section of the balloon varies with the geometry of the transmission path, as borne out by our own measurements on *Echo* I and the correct theoretical treatment[1]. Thus the 1·3 db. factor used by Carru *et al.* can be omitted, leaving a net loss of 0·5 db., or a predicted received level of −143·0 dbm. This is in good agreement with the value reported, −142 dbm. ± 1 db.

Accurate information regarding the Holmdel transmission is available on request to any independent experimenters who need such information to evaluate their own measurements.

The results of the radio transmission tests supported by the U.S. National Aeronautics and Space Administration and using the *Echo* I satellite over the period August 1960–March 1961 have been evaluated and will be published shortly.

PHYSICS

Apparent Intermediate Supervelocity of Detonation

THE transition from the low to the high detonation velocity in a cylindrical dynamite charge is seen as a rather sharp bend in the streak camera curve. At the transition point the high velocity often starts with an apparent supervelocity which is much greater than the stationary high velocity. The reason is probably that the high velocity is initiated by the low velocity at a point on the axis. Good accordance between observed and calculated values is obtained if it is assumed that the high-velocity detonation sets off from a point a little behind the luminous zone of the low velocity. This accords with the fact that the latter, according to instantaneous photographs, is at the front of the preliminary reaction zone of Selberg and Sjölin[1].

An analogous phenomenon is the initiation of a cylindrical charge by an axial shock-wave. In that case the detonation sets out from a circular, coaxial area on the shock front, the radius of which is smaller than the radius of the charge[2], and the maximum apparent supervelocity goes to infinity.

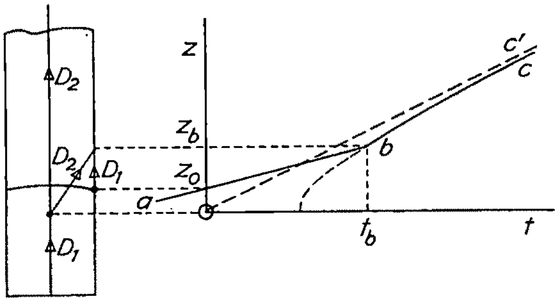

Fig. 1

Fig. 1 gives a schematic picture of the course of events. To the left is shown the cylindrical charge with the front of the low velocity and the starting point of the high velocity when the high velocity starts ($t = 0$). In the time diagram to the right, *abc* shows the course of the luminous front at the envelope surface of the charge. It is obtained from the streak camera photography. *b* is the point where the high-velocity front overtakes the low-velocity front. *Oc'* shows the front of the high-velocity detonation along the axis. The slope of *ab* gives the low velocity D_1, and the derivative of the curve

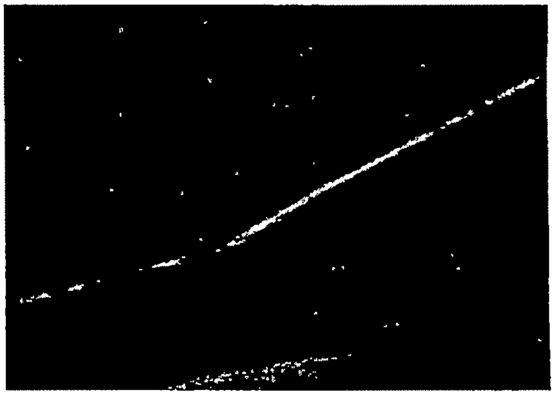

Fig. 2

bc in b gives the maximum apparent supervelocity D_2'. The slope of the asymptote Oc' to the curve bc gives the steady high velocity D_2. If R denotes the radius of the charge, z_b and z_o ordinate values according to Fig. 1, $n = D_2/D_1$ and $m = D_2'/D_2$, we get $z_b = R\sqrt{m^2 - 1}$, $z_o = z_b\ (1 - m/n)$ and $t_b = (z_b - z_0)/D_1$.

Fig. 2 shows a streak camera photo of a charge of gelatinized ammonium dynamite with 35 per cent nitroglycerine/nitroglycol (1 : 1). It was initiated by a donor charge of the same explosive detonating with high velocity. Both charges were in a common tube of 'Plexiglass' with 36 mm. interior and 40 mm. exterior diameter separated by an air gap of 40 mm. The transition point was 27 mm. from the end of the receiver. From Fig. 2 we get: D_1 = 3,030 m./s., D_2 = 5,760 m./s. and D_2' = 7,350 m./s. This gives $n = 1{\cdot}89$, $m = 1{\cdot}28$, $z_b = 22{\cdot}5$ mm., $z_o = 7{\cdot}3$ mm. and $t_b = 5{\cdot}0$ µs.

Damped Free Oscillations of a Gyroscopic System

THE equations of motion of a gyroscopic system consisting of a symmetric rotor of axial moment of inertia C mounted in heavy gimbals are :

$$\left.\begin{aligned} A\ddot{\theta}_1 + c_1\dot{\theta}_1 + Cn\dot{\theta}_2 &= 0 \\ -Cn\dot{\theta}_1 + B\ddot{\theta}_2 + c_2\dot{\theta}_2 &= 0 \end{aligned}\right\} \quad (1)$$

where n is the constant angular velocity of the rotor about its axis ; θ_1 and θ_2 are small angles denoting rotations about the outer and inner gimbal axes respectively ; c_1 and c_2 are the corresponding coefficients of viscous friction ; A is the moment of inertia of the entire system about the outer gimbal axis and B that of the inner gimbal plus rotor about the inner gimbal axis. These equations are based on three principal assumptions : (1) the centres of mass of the rotor and of the gimbals lie at the intersection of the gimbal axes, (2) the axis of the rotor is nearly perpendicular to the axis of the outer gimbal, and (3) the axes of rotation are principal axes of inertia. If there is no friction at the gimbal axes, equations (1) define a free, undamped oscillation in which the rotor axis performs a conical whirl about its central position and the gimbals vibrate at frequency $p = Cn/\sqrt{AB}$.

Now it is well known that friction normally reduces the frequency of free vibrations of an oscillatory mechanical system. The gyroscopic motion defined by equations (1), however, provides an exception to the rule, as may be seen by eliminating θ_2 from (1). This gives

$$\dddot{\theta}_1 + \left(\frac{c_1}{A} + \frac{c_2}{B}\right)\ddot{\theta}_1 + \left(\frac{c_1c_2 + C^2n^2}{AB}\right)\dot{\theta}_1 = 0 \quad (2)$$

Equation (2) represents a damped free oscillation the frequency, p_d, of which is :

$$p_d = \sqrt{\left[\frac{C^2n^2}{AB} - \frac{1}{4}\left(\frac{c_1}{A} - \frac{c_2}{B}\right)^2\right]} \quad (3)$$

Thus the frequency of the damped oscillations will normally be less than that of the undamped oscillations. However, when:

$$\frac{c_1}{A} = \frac{c_2}{B} \quad (4)$$

an exceptional and interesting case occurs, for then p_d is independent of both c_1 and c_2. This condition might easily arise in practice. Even if it were only approximately true, the decrease in frequency due to damping would still be very small: it would, for example, be considerably less than that associated with a conventional system having a single degree of freedom.

It is also interesting to note that if (4) is satisfied, the motion can never be critically damped and must remain oscillatory, even although the damping coefficients and hence the rate of decay of oscillations may become very large.

CHEMISTRY

Precision and Accuracy in Gas Chromatographic Analysis

THE extensive use of gas chromatography to provide quantitative information on the composition of mixtures of organic compounds has prompted an investigation designed to give some indication of the reliability expected. With the exception of the gas density balance, the commonly used detectors do not give a response which can be predicted accurately from the physical or chemical properties of the compounds concerned, so that for highest accuracy calibration is necessary. The development of high-sensitivity detectors has made possible the achievement of high column performance by virtue of the smaller sample loads used, but since reproducible loading becomes more difficult the use of internal standards becomes desirable.

The most widely used high-sensitivity detector is the argon ionization detector devised by Lovelock[1], which combines very high sensitivity with a high degree of stability to changes in rate of flow of gas, temperature and pressure. The linear range of the detector at any given applied voltage is limited but adequate, and a wide dynamic range is achieved by change of applied voltage.

The argon detector in its present form is of robust construction, and when used with suitable power supply and electronic circuitry is capable of giving very accurate and reproducible results. Experience shows that the major cause of detector malfunction is through contamination of the argon carrier gas with either organic or inorganic substances.

Quantitative results obviously rely on the proper functioning of the detector, and a knowledge of the way in which accuracy and reproducibility can be affected is essential.

Organic contamination of the argon entering the detector causes an increase in the background current. Superimposition of a chromatographic peak on this background could result in the observed response extending into the non-linear region. Variation in the level of organic contamination produces a variation in the detector background current, which appears as an unstable chromatogram baseline. Deposition of organic material derived from stationary phase decomposition on the collecting electrode can result in low detector response. Common sources of organic contamination are cylinder gauge heads, unclean tubing used to convey argon to the column and stationary-phase stripping from the column used.

The process of ionization in the detector is brought about by the transfer of the excitation energy of metastable argon on collision. The formation of sufficient metastable argon for normal detector operation requires the collision of molecular argon with electrons acquiring sufficient energy by acceleration in the applied potential field. The effect of some inorganic contaminants is to prevent the electrons acquiring sufficient energy to create metastable argon; the response of the detector is thereby destroyed. (This effect has been used by Willis[2] to produce a high 'negative' response for permanent gases in a detector fed with an argon stream containing an organic component.) Recent results published by Lovelock[3] show that the greatest effect is produced by water vapour, the sensitivity of the detector being reduced ten-fold by a change in water vapour concentration from about 30 p.p.m. to about 1,000 p.p.m. At less than 30 p.p.m. of water vapour the detector response is constant. The effect of other inorganic contaminants is similar but sets in at higher concentrations. With oxygen, reduction in sensitivity begins at 100 p.p.m. and with nitrogen at 1,000 p.p.m.

It is clear that in order to achieve constant sensitivity and hence reproducible chromatograms it is essential to eliminate or reduce to acceptable limits contamination of the argon supply or to maintain at a constant level deliberately introduced contaminants. Sources of contamination are listed in Table 1.

Table 1

Site of contamination	*Contaminant*	*Source*	*Effect*
Argon cylinder	Water vapour	Present in cylinder	Low and variable sensitivity
Rubber or plastic argon line	Water vapour, permanent gases	Diffusion through walls of tubing	Low and variable sensitivity
Column	Organic bleed	Unstable stationary phase or operation at too high temperature	High background current, non-linearity, variable sensitivity

Contamination can be avoided by conveying the argon from the cylinder to the column through clean metal tubing and a molecular sieve trap, and by pretreating the column at a temperature in excess of the proposed working temperature.

In order to determine the precision obtainable from a gas chromatograph employing an argon ionization detector, a two-component gas mixture was sampled automatically at regular intervals and chromatographed on a standard Pye argon chromatograph (Fig. 1). Contamination of the argon supply was prevented by passing the argon from the cylinder through a molecular sieve Linde 5*A* trap and thence to the column in copper tubing which had been cleaned previously by heating to a dull red in a stream of argon. The column used was 10 per cent squalane on 100/120 mesh alumina which had been rendered stable by heating at 100° C. for 24 hr. in a stream of argon. The column temperature was 75° C. and the carrier gas flow-rate 30 ml./min. The sample gas was passed through the automatic sampling valve at about 5 ml./min. to atmosphere, no attempt being made to control the pressure since small variations in the volume injected would not affect the results obtained. Under these conditions the gas mixture consisting of approximately equal amounts of propane and butane was eluted in 8 min. with complete resolution of the two components. A fresh injection of 0·30 ml. of argon containing 1,600 p.p.m. of organic material was made every 10 min. and the run was continued for 4 days. The ratio of the peak heights of the two components was then determined for each injection.

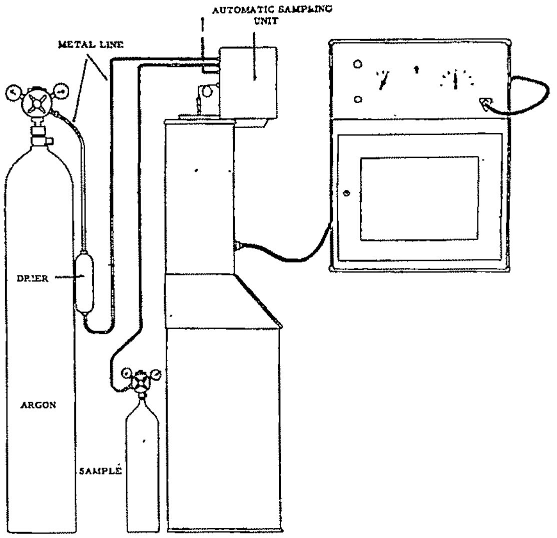

Fig. 1. Apparatus used in the determination of reproducibility

The results obtained (Fig. 2) show an overall spread of about 1 per cent for 110 consecutive determinations. The standard deviation is 0·23 per cent and the 95 per cent confidence limits are ± 0·35 per cent. The base-line deviation was 1·7 per cent full-scale deflexion over 4 days. The sample load added varied by about ± 4 per cent. A second series of injections was carried out, this time using an integrating amplifier to give an

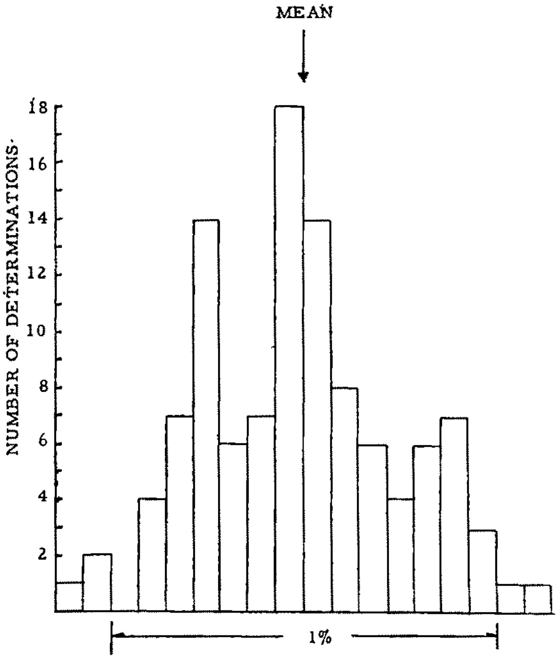

Fig. 2. Variation in peak height ratios from 110 consecutive chromatograms

accurate measurement of peak areas; an overall spread similar to that quoted was obtained.

An Organo-clay Complex for the Separation of Isomeric Dichlorobenzenes using Gas Chromatography

White[1] has shown that dimethyldioctadecyl ammonium bentonite is particularly suitable as a stationary phase for the chromatographic separation of aromatic and aliphatic compounds, while Hughes, White and Roberts[2] have shown that this material is equally suitable for the separation of isomeric xylenes, toluidines and cresols. Further work by Cowan and White[3] has shown that similar organo-clay complexes are adsorbents for phenols, the adsorbents showing widely differing specificity for the various isomers, and from the data presented the authors propose that the electronic transitions occurring within the sorbate molecules are the main contributory forces governing the extent of adsorption. In consequence, the use of organo-clay complexes for separating isomeric compounds is particularly appropriate and a further example, the separation of dichlorobenzenes, has been investigated and the results obtained compared with those for a conventional liquid stationary phase.

The relative retention volumes for the dichlorobenzenes are given in Table 1 and these are expressed relative to the *para* isomer—in all cases the values are corrected for the dead space of the column. A typical chromatogram is shown in Fig. 1 and this was obtained with a column 200 cm. long × 0·4 cm. bore containing 10 gm. 60–80 mesh 'Celite' as a diluent for 1·0 gm. of dimethyldioctadecyl ammonium bentonite ('Bentone 34', Abbey Chemicals, Ltd.)—the detector was a β-ray ionization unit as supplied by Gas Chromatography, Ltd.

It is noted that using 'Bentone 34' as a stationary phase, a complete resolution of the dichlorobenzenes is obtained whereas with the silicone oil virtually no separation of the *para* and *meta* isomers is effected. Furthermore, even with a capillary column and dinonyl sebacate as a stationary phase complete resolution of these isomers is not possible. It is also noted that, with the solid 'Bentone' stationary phase, symmetrical elution peaks are obtained.

Table 1

	Relative retention volume			
	Silicone oil		'Bentone 34'	
	80° C.	110° C.	80° C.	110° C.
Benzene	0·08	—	0·11	—
Chlorobenzene	0·28	0·37	0·68	0·79
p-Dichlorobenzene	1·00	1·00	1·00	1·00
m-Dichlorobenzene	1·02	1·02	2·23	2·14
o-Dichlorobenzene	1·17	1·12	5·64	4·80
1,2,4-Trichlorobenzene	3·11	2·47	—	16·0
	Specific retention volume (ml.)			
p-Dichlorobenzene	440	161	840	246

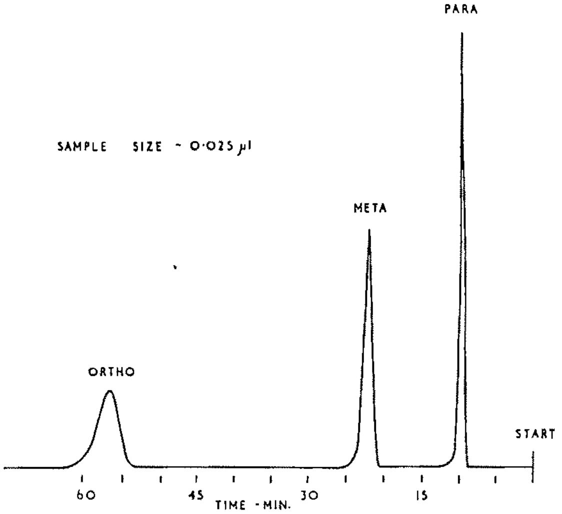

Fig. 1

From the results and those obtained by previous workers, it is suggested that the use of organo-clay complexes as stationary phases in chromatography warrants more detailed investigation. Since interlamellar distances within the clay complex play an important part in the adsorptive properties, and as these distances are governed by the size of the substituting amine ion[4], it is expected that further work will reveal that it is possible to prepare an organo-clay stationary phase of pre-determined resolving characteristics for a specific separation of organic compounds.

The Possibility of obtaining E.M.F. directly from Acid-Base Reactions: Electrodes of the Third Kind reversible to Alkaline Earth and Other Ions

Some years ago Shedlovsky[1,2] suggested that proton transfer reactions could give rise directly to e.m.f., and apparently confirmed this idea by demonstrating that a glass electrode, coated with lauric acid and barium laurate, acted as a barium electrode. There is a simpler explanation of this result, however: namely, the glass electrode with lauric acid and barium laurate acts as an electrode of the third kind. In a barium chloride solution saturated with these substances, the activities of barium and hydrogen ions must be related by the equation:

$$a_{\mathrm{H}} = (k_{\mathrm{HL}}^{2}/k_{\mathrm{BaL}_2})^{1/2} \cdot a_{\mathrm{Ba}}^{1/2}$$

k representing the thermodynamic solubility product. In such solutions the glass electrode, responding to

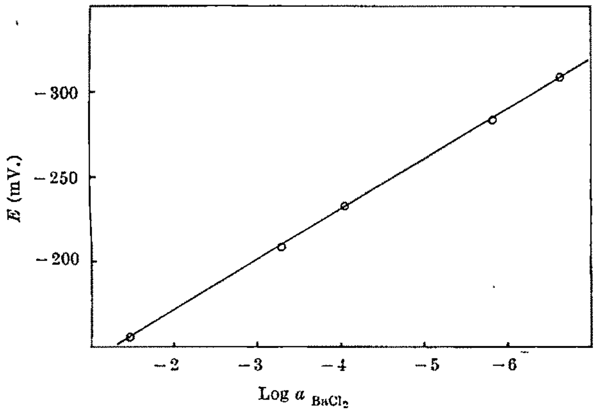

Fig. 1. E.m.f. of the cell: $\mathrm{Ag,AgCl}\Big/\begin{matrix}\mathrm{BaCl_2\ sat.\ with}\\ \mathrm{Ba}L_2\ \text{and}\ \mathrm{H}L\end{matrix}\Big/$glass electrode

hydrogen ion activity in the normal way, would therefore appear to act as a barium electrode.

To check this possibility, solutions of barium chloride ranging in concentration from 0·005 to 0·5 *M* have been shaken with mixtures of solid lauric acid and solid barium laurate at 25° C. and the potential difference between a glass and silver–silver chloride electrode then determined in each of these solutions. The results of these measurements are shown in Table 1 and Fig. 1, in which the straight line has been drawn with the theoretical slope of 29·6 mV. per logarithmic unit. The points referring to 0·5, 0·1 and 0·01 *M* solutions were obtained with one glass electrode and the others with a second glass electrode which was also measured in 0·5 *M* solution. For both electrodes the e.m.f. was set equal to -156 mV. in the latter solution in order to fit the data for the two electrodes together. The measurements are seen to give the expected result. A further check is possible, since the potential difference between the glass and silver chloride electrode in 0·01 *N* hydrochloric acid was also determined. The value was $-101·3$ mV. compared with the value of -156 mV. in the 0·5-*M* barium chloride solution. Since the e.m.f. of the chain:

$$\mathrm{Ag,AgCl}\Big/\begin{matrix}\mathrm{BaCl_2\ sat.\ with}\\ \mathrm{H}L\mathrm{(s)\ and\ Ba}L_2\mathrm{(s)}\end{matrix}\Big/\begin{matrix}\text{glass}\\ \text{electrode}\end{matrix}-\begin{matrix}\text{glass}\\ \text{electrode}\end{matrix}\Big/\mathrm{HCl}\Big/\mathrm{AgCl,Ag}$$

should obey the equation:

$$E=(RT/2F)\ln(k^2_{\mathrm{H}L}/k_{\mathrm{Ba}L_2})+(RT/2F)\ln(a_{\mathrm{BaCl_2}}/a^2_{\mathrm{HCl}})$$

the ratio $(k^2_{\mathrm{H}L}/k_{\mathrm{Ba}L_2})$ can be calculated. The value thus obtained was $3·9 \times 10^{-9}$. Combining this with the value $k_{\mathrm{Ba}L_2}=1·2 \times 10^{-11}$, calculated from solubility data[4], one then obtains for the solubility product of lauric acid in water at 25°, $k_{\mathrm{H}L}=2·15 \times 10^{-10}$, and hence for the molality of undissociated lauric acid in the saturated solution, $2·15 \times 10^{-5}$, if lauric acid is assumed to have a dissociation constant of 10^{-5}. Finally, the solubility of lauric acid at 25° C. is found to be $3·6 \times 10^{-5}$ mole kgm.$^{-1}$ water. This may be compared with the value $1·9 \times 10^{-5}$ mole l.$^{-1}$ reported by McBain and Eaton[5] from conductivity measurements.

This explanation of Shedlovsky's results implies that the laurate layers on his electrodes were porous or cracked, so that the underlying glass surface was in reality in contact with solution. It also implies that the solutions inside and outside his glass electrodes differed in *p*H, contrary to what he believed. This must have been so in fact, in view of the much smaller buffer capacity of his solutions compared with that of the solids barium laurate and lauric acid, which would therefore determine the equilibrium *p*H of the solution.

Table 1

E.m.f. of the cell: $\mathrm{Ag,AgCl}\Big/\begin{matrix}\mathrm{BaCl_2\ sat.\ with}\\ \mathrm{Ba}L_2\ \text{and}\ \mathrm{H}L\end{matrix}\Big/$glass electrode

M ($\mathrm{BaCl_2}$)	$\gamma_{\pm}$ (Ref. 3)	E_{25° (mV.)
0·005	0·774	$-308·8$
0·01	0·716	$-283·2$
0·05	0·564	$-233·1$
0·1	0.500	$-208·8$
0·5	0·397	$-156·0$

It should obviously be possible by this method to obtain electrodes reversible to the other alkaline earth ions, while by varying the acid the list might be extended still further. The method is especially convenient since it makes use of the glass electrode.

Although it is true that the e.m.f. of cells of the type tested does arise directly from acid-base reactions, the detailed mechanism is probably not that suggested by Shedlovsky. Even with the simpler mechanism suggested here, however, acid-base reactions might still be the origin of some bioelectric potentials.

Spectrum of Vanadium in the Tri-positive Oxidation State (V^{3+}) in Tetrahedral Co-ordination[†]

Vanadium in the tri-positive oxidation state has two unpaired electrons in the 3*d* shell. The interaction of the crystalline electric field with the two *d*-shell electrons has been treated theoretically for fields of various symmetries[1–3]. Most of the information concerning the electronic structure of V^{3+} comes from work on compounds in which the metal ion is co-ordinated to six ligands.

The optical spectra of V^{3+} in alums[4] and in corundum[2,5], where the co-ordination is to six oxygens, agree reasonably well with the calculated energy-level diagrams. The *Dq*-value which fits these data best is 1,800 cm.$^{-1}$. Using the strong field theory, McClure[6] gives the octahedral site preference energy as 12·3 k.cal./mole for oxide lattices.

Since energy-levels are profoundly influenced by a change in co-ordination number, it is of interest to learn more about four co-ordinate V^{3+} (ref. 7). We have now obtained the spectrum of V^{3+} substituted for Al^{3+} in the $CsAlCl_4$ lattice (Fig. 1). Single crystals of this material were grown containing a few tenths per cent of V^{3+}. They are blue in colour. Tetrahedral $AlCl_4^-$ ions have been shown to exist as structural units in the $NaAlCl_4$ lattice[8] and, presumably, are present also in the $CsAlCl_4$ lattice.

The room temperature spectrum is characterized by four bands with maxima at 15,000; 10,250; 9,400; and 8,250 cm.$^{-1}$. The total oscillator strength

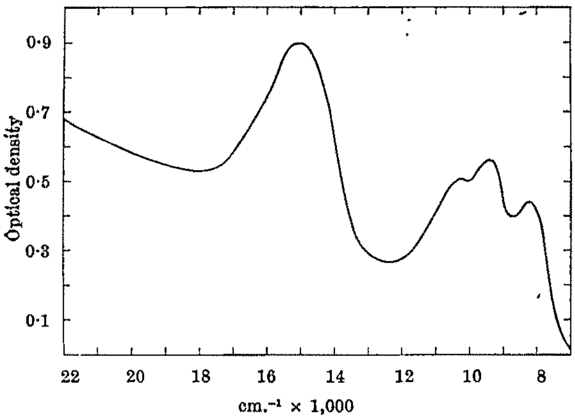

Fig. 1. Absorption spectrum of V^{3+} in $CsAlCl_4$ at room temperature

in the region 17,000–7,000 cm.$^{-1}$ is about 10^{-3}. The bands overlap and are not symmetrical. They can be expected to show additional structure at low temperatures. Liehr and Ballhausen's energy-level diagram, based on pure crystal field theory calculations for a d^2 system in a tetrahedral field[1], gives two $^3T_1$ levels at 16,000 and 9,000 cm.$^{-1}$ and a $^3T_2$ level at 5,000 cm.$^{-1}$ for $Dq = -500$ cm.$^{-1}$.

Tripositive vanadium can also be situated in an octahedral chloride ion environment. This would appear to be the case, for example, in molten lithium chloride-potassium chloride eutectic[9,10]. In this solvent, two bands are found at 18,000 and 11,000 cm.$^{-1}$ corresponding to transitions from the $^3T_1$ ground-state to $^3T_1$ and $^3T_2$ excited states, respectively. Good agreement with the theoretical energy-level diagram is obtained with $Dq = 1{,}200$ cm.$^{-1}$. Using Dq-values of -500 and 1,200 cm.$^{-1}$ for tetrahedral and octahedral environments respectively, one finds the octahedral site preference energy for V^{3+} in chloride lattices to be 10·5 k.cal. on the strong field model.

Spectral intensity calculations on $CuCl_4^{2-}$ and $CoCl_4^{2-}$ ions led Ballhausen and Liehr[11] to postulate that tetrahedral complexes display a certain degree of covalency. It would appear from the present work that covalent bonding in VCl_4^- affects not only the intensity of the spectrum but also the energy-level structure of the ion. An extension of the theory, which would include covalency effects, will undoubtedly be required in order to obtain better agreement with the experimentally observed spectrum.

The technique of isomorphous substitution of a transition metal ion in a colourless host lattice was applied in the present case to obtain a particular configuration difficult to produce by other means. Other examples of host lattice configuration stabilization have been reported for tetrahedral Co^{2+} and Ni^{2+} in oxide[8] and chloride[11] lattices. The phenomenon is being put to use in work on a number of other transition metal ions.

This work was performed under the auspices of the United States Atomic Energy Commission.

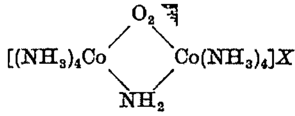
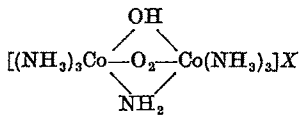
Structure of Polynuclear Cobalt Complexes

It is known that molecular oxygen will react with the hexaminecobalt(II)-ion, whereby different kinds of complexes are formed. Among these complexes, the following types are described in the literature:

$$[(NH_3)_5Co{-}O_2{-}Co(NH_3)_5]X_5$$





Lately the bonding in these compounds has been much discussed, and it therefore appears to be of considerable interest to establish their structures. Work on the crystal structures of compounds belonging to the first of the above-mentioned types have been going on at this institute for several years. The following compounds have been investigated by the usual X-ray methods:

$$[(NH_3)_5Co{-}O_2{-}Co(NH_3)_5](NO_3)_5$$

$$[(NH_3)_5Co{-}O_2{-}Co(NH_3)_5](NO_3)_4.HF_2.(H_2O)_2$$

The nitrate was found to have tetragonal symmetry, corresponding to the space group $P4_2nm$ (No. 102). The dimensions of the elementary cell are $a = b = 11 \cdot 94$ Å. and $c = 8 \cdot 06$ Å. The cell contains two formula units. Parameter values for all the atoms with the exception of the hydrogens have been determined by a three-dimensional Fourier summation (Table 1). The reliability index R is calculated to be 0·20.

Table 1. Parameter Values for $[(NH_3)_5Co{-}O_2{-}Co(NH_3)_5](NO_3)_5$. Space Group $P4_2nm$

O	*b*	4			

The constitution of the cation complex can be seen from Fig. 1. It will be noted that the axis of the peroxide group is perpendicular to a line connecting the two cobalt atoms, as predicted by Vlček[1].

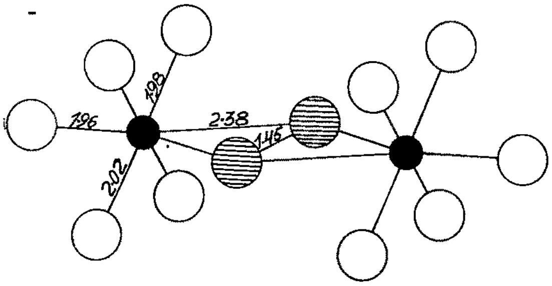

Fig. 1. Configuration of the ion $[(NH_3)_5Co-O_2-Co(NH_3)_5]^{5+}$. Shaded, O; white, NH_3; black, Co

The compound containing the fluoride as well as the nitrate anion has been prepared by treating the nitrate with a concentrated aqueous fluoric acid solution. The following crystallographic data have been obtained for this compound: space group *Pbca* (No. 61) and unit cell dimensions $a = 13{\cdot}14$ Å., $b = 12{\cdot}21$ Å. and $c = 14{\cdot}14$ Å. The unit cell contains four formula units.

As expected, the compound is composed of complex groups, as indicated in Fig. 1, in addition to water, nitrate groups and hydrogen difluoride groups. The atomic parameter values obtained so far give an *R*-factor of 0·34. A least-square refinement of the structure has therefore been undertaken.

A complete report of both these and related structure investigations will be published elsewhere.

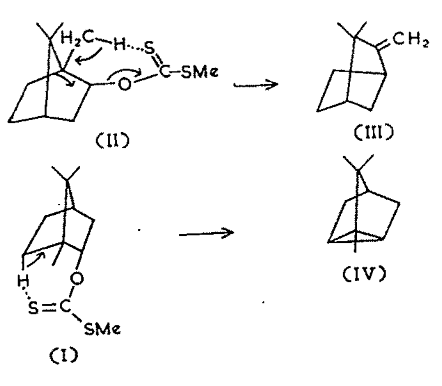
Pyrolysis of Esters of Borneol and *iso*Borneol

It is generally believed that esters pyrolyse to give the products of *cis* elimination in a six-membered cyclic transition state[1]. Recently, however, products corresponding to a *trans* elimination have been shown to be formed by the pyrolysis of methyl xanthates of some substituted *cyclo*hexanols[2]. The pyrolyses of xanthates and acetates of 1-alkyl*cyclo*hexanols give predominantly the more stable endocyclic olefins[3], and both *cis* and *trans* elimination have been observed in pyrolyses of chlorosulphites[2], and sulphoxides[4].



Tschugaeff isolated bornylene, containing some tricyclene, from the pyrolysis of bornyl methyl xanthate[5]. Hückel has isolated camphene from the pyrolysis of *iso*bornyl xanthate[6], and camphene has been shown to be a pyrolysis product of bornyl sulphites[7]. We have examined the pyrolysis products of methyl xanthates and benzoates of borneol and *iso*borneol; cf. (I) and (II), respectively. The methylxanthates were decomposed using a bath at 300°, at which temperature the decomposition was almost instantaneous; the benzoates decomposed comparatively slowly when the bath was at 350°. The products distilled off and were analysed and separated by gas-liquid chromatography (Table 1).

Table 1. Composition and Configuration of Pyrolysis Products. (Figures in parentheses are percentage retention of configuration)

	Bornylene (per cent)	Tricyclene (per cent)	Camphene (per cent)
Bornyl methyl xanthate	70 (100)	13·5	16·5 (~ 30)
*Iso*bornyl methyl xanthate	38·5 (92)	—	61·5 (~ 100)
Bornyl benzoate	24·5 (97)	21·5	54 (~ 30)
*Iso*bornyl benzoate	—	13	87 (~ 30)

The bornylene was probably formed through the classic *cis* elimination mechanism[1], but this mechanism cannot explain the formation of camphene (III) and tricyclene (IV). Maccoll[8] and co-workers have emphasized the similarity between the gas-phase pyrolyses of alkyl halides and their unimolecular solvolyses, and emphasize the importance of charge separation in the transition state[2]. Following these ideas, we can explain the composition of the product by assuming that the part of the reaction which gives camphene and tricyclene is 'quasi-heterolytic'[8], because the initial elimination product of the solvolyses of bornyl and *iso*bornyl chlorides is always camphene. The amount of camphene is greater in the pyrolyses of the *iso*bornyl esters, and *iso*bornyl compounds form carbonium ions much more readily than do bornyl compounds. Similarly, carbonium ions should be generated much more readily by benzoates than by xanthates, and the former always give more camphene and less bornylene; although the temperature difference may make this comparison misleading.

The formation of camphene of high optical purity from *iso*bornyl methyl xanthate suggests that there is a seven-membered cyclic transition state, in which breaking of a C—H bond is synchronous with the migration of C—C bond electrons, and separation of the leaving group, but the formation of partially racemic camphene from the other esters shows that for them the decomposition must be step-wise, with loss of asymmetry at some stage. A similar synchronous mechanism can be written for the formation of tricyclene (IV).

As might be expected, the bornylene is more than 90 per cent optically pure, and bornylene and camphene and reactants have the same configuration. Because in these pyrolyses we observe products typical of a Wagner–Meerwein rearrangement, we have stressed the analogy with carbonium-ion chemistry, but our cyclic mechanisms could be considered to have some homolytic character, and it is also possible that some 1 : 1-elimination might lead to a carbene intermediate.

We are grateful to Dr. D. J. Cram for interesting discussions.

BIOCHEMISTRY

Hydrolysis of Paraoxon in Mammalian Blood

Several publications have indicated that in the detoxication of paraoxon (diethyl *p*-nitrophenyl phosphate, '*E*600,' 'Mintacol') the mammalian blood serum might be of importance[1-3]. Aldridge[4] was first to describe the existence of an *A* esterase (aryl-, aromatic esterase) which hydrolyses paraoxon. This enzyme occurs in the sera of various species[1], but the extent of its involvement in the metabolism of paraoxon is not yet clear[5,6]. Among other properties, the arylesterase cleaves phenyl acetate[7], and it has been shown with this substrate that the enzyme requires the presence of calcium for activity[8,9]. The arylesterase is activated by calcium and inhibited by sodium ethylenediaminetetraacetate and numerous other compounds[8-11]. In human blood plasma it occurs in fraction IV–1[12,13]. Since preliminary experiments indicated that in addition to this arylesterase, at least one more factor might be responsible for the hydrolysis of paraoxon in blood serum or plasma, we undertook the present investigations.

The cleavage of paraoxon was followed in a Cary recording spectrophotometer, by determining the amount of *p*-nitrophenol liberated at a wave-length of 4000 Å., or in some of the experiments at 3470 Å. The temperature was kept constant at 37° C., the *p*H at 7·9. The 0·1 *M* *tris*(hydroxymethyl)aminomethane buffer was 4·5 × 10^{-3} *M* in substrate and 2·4 per cent in propylene glycol. The results were calculated from the initial rates of hydrolysis.

Fig. 1 summarizes some of the results. As shown in Fig. 1*A*, fresh pooled human serum hydrolyses paraoxon at an appreciable rate. This activity was inhibited only 86 per cent by a 0·01 *M* concentration of ethylenediaminetetraacetate. Since the cleavage of paraoxon by purified human arylesterase (fraction IV–1) was completely abolished by a concentration of ethylenediaminetetraacetate 20 times lower (*D*), clearly the residual activity in the serum was not due to arylesterase, but to something else. The splitting of paraoxon, however, was completely blocked when the serum, in addition to ethylenediaminetetraacetate, contained 10^{-3} *M* aurin tricarboxylic acid ammonium salt (aluminon) (*A*). While looking for the source of the activity resistant to ethylenediaminetetraacetate we found that human albumin (fraction V or crystallized) also hydrolyses paraoxon, and indeed this hydrolysis is inhibited by aluminon (*C*). Even after 18 hr. of incubation ethylenediaminetetraacetate had no effect on the albumin. On the other hand, the enzymic hydrolysis of paraoxon by fraction IV–1, as indicated above, was inhibited by ethylenediaminetetraacetate, and unaffected by aluminon (*D*). When plasma arylesterase (fraction IV–1) and albumin (fraction V) were mixed (*B*) the results with selective inhibitors were similar to those with normal serum. However, in the presence of albumin the activity of fraction IV–1 is somewhat higher than expected.

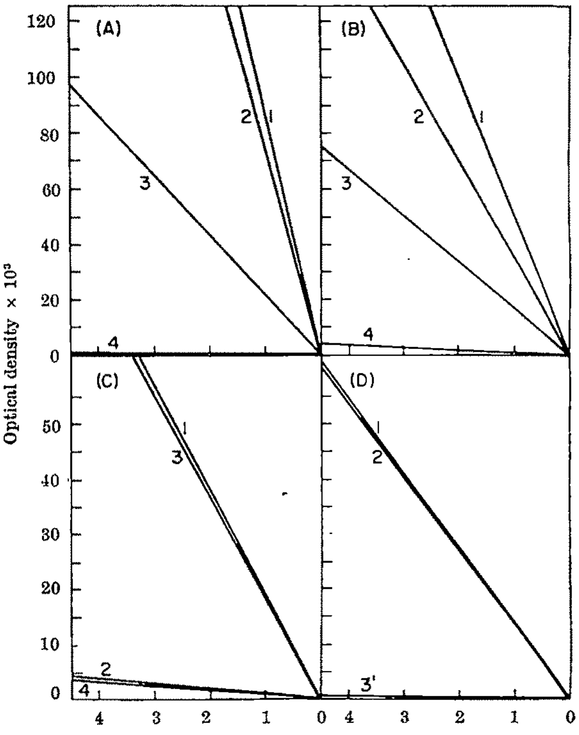

Fig. 1. Inhibition of the hydrolysis of paraoxon in human blood serum (*A*) and plasma fractions (*B*, *C*, *D*). Dilutions : *A*, pooled serum, 1 : 20 v/v; *B* fractions IV–1, 1 mgm./ml. + V, 4 mgm./ml. w/v; *C*, fraction V, 4 mgm./ml.; *D*, fraction IV–1, 0·5 mgm./ml. (1) control; (2) aluminon 1 × 10^{-3} *M*; (3) ethylenediaminetetraacetate 1 × 10^{-2} *M*; (3′) same 5 × 10^{-4} *M*; (4) aluminon 1 × 10^{-3} *M* + ethylenediaminetetraacetate 1 × 10^{-2} *M*

The behaviour of albumin with paraoxon was further explored with the help of various agents. Albumin (or a factor in albumin) was inhibited to about 50 per cent (I_{50}) by 2 × 10^{-4} *M* aluminon. This inhibition was not reversed by overnight dialysis. Lineweaver–Burk-type plots[14] showed a non-competitive inhibition. Some other enzyme inhibitors or activators such as oxalic acid (0·01 *M*) or mercuric chloride (5 × 10^{-4} *M*) nevertheless gave negative results. Since the preparations used were not activated by Sr^{2+} and Ba^{2+}, the presence of a phosphoryl phosphatase[15] is unlikely. But albumin was definitely inhibited by sodium, potassium or lithium chloride. The I_{50} values were roughly 0·5 *M*. Albumin was more sensitive to monovalent anions than to cations; the I_{50} of sodium bromide is about 0·1 M; that of sodium iodide, 0·01 M.

Fluoride was not tried as an inhibitor because we had seen that 10^{-3} M potassium or sodium fluoride catalyses the hydrolysis of paraoxon at a relatively high rate. The rate of this reaction was similar to the one catalysed by albumin in the concentration shown in Fig. 1,*C*. Other metals and organic compounds, among them the cholinesterase reactivator pyridine-2-aldoxime methiodide (2–PAM), used frequently in paraoxon poisoning[16,17] had an analogous effect. (The subject was recently reviewed extensively by O'Brien[18].) This catalytic activity at a 1 × 10^{-3} M concentration decreased in the following order: 2–PAM, sodium fluoride, *p*-chloromercuriphenylsulphonic acid, zinc sulphate, cadmium sulphate, manganese chloride, cobalt chloride, mercuric chloride. The zinc-ethylenediaminetetraacetate was not active.

Reagents and procedures known to denature proteins also destroyed the activity of albumin. For example, albumin became inactive after heating it at 70° C. for 10 min. Furthermore, 4 M urea abolished 80 per cent of the activity in 1 hr. Calcium chloride protected the protein; in the presence of 0·01 M calcium chloride only 40 per cent was inactivated. In contrast to the results with arylesterase[19], lanthanum chloride was less effective than calcium chloride. Other alkaline earth salts (magnesium chloride, strontium chloride) also protected the albumin, but less than calcium chloride.

When the investigations were expanded to serum proteins of other mammals, swine serum was found to behave like human serum (see Fig. 1,*A*). Serum albumin of other animals also destroyed paraoxon. The relative activity of the various albumin fractions decreased in the following order: rabbit, human, porcine, bovine, equine. Under our conditions, 100 mgm. of human albumin hydrolysed 2·4 μM paraoxon per hour. These albumins were also inhibited to a varying extent by aluminon but unaffected by ethylenediaminetetraacetate, etc. On the other hand, ethylenediaminetetraacetate blocked partially or completely the hydrolysis of paraoxon in the sera of pig, horse, rabbit, guinea pig, and sheep.

Lactalbumin, lysozyme, and human plasma cholinesterase (fraction IV–6–3) hydrolysed paraoxon to a negligible extent. Like arylesterase, albumin also splits phenyl acetate. While the relative ratio of hydrolysis-rates of phenyl acetate to paraoxon by fraction IV–1 was about 600 : 1 in the two systems employed, it became 1 : 1 with albumin as source of 'enzyme'.

In preliminary studies with the Spinco model *E* analytical ultracentrifuge fraction V gave a single peak, but in starch-gel electrophoresis human albumin from various sources showed contamination by globulin. However, in experiments where the sample had been pre-treated with the inhibitor aluminon, the albumin band migrated at a higher speed in front of the field.

The similarities and dissimilarities between the hydrolysis of paraoxon and other 'substrates' of albumin, for example, β-naphthylacetate, β-carbonaphthoxycholine[10], carbamates[12,20], di*iso*propoxy phosphoryl fluoride[21], indophenyl acetate[22] and other details are discussed elsewhere.

Our present experiments indicate that mammalian serum albumin (or a factor in it) hydrolyses paraoxon at an appreciable rate. Selective inhibitors can distinguish its activity from that of serum arylesterase.

The kind co-operation of Drs. W. Jensen, R. Rice and M. Westerman in some of the experiments is gratefully acknowledged.

Precautions in the Use of Ferri- or Ferrocyanide for the Study of Hæmoproteins

POTASSIUM ferri- and ferro-cyanide are extensively used as oxidizing and reducing reagents respectively, or as buffer systems in the study of the oxidation-reduction potentials of hæmoproteins and other biological compounds. It was shown, however, by Schönbein and some other workers, especially Baudisch and Bass[1], that these reagents easily undergo photodecomposition accompanied by the liberation of a certain amount of cyanide. Solutions of these reagents must therefore be not only freshly prepared, but also well protected from light, especially when used for the study of hæmoproteins which may have high affinities for cyanide, forming with it well-defined complexes.

In this respect it may be interesting to recall a red compound described by Bock[2] as 'photomethæmoglobin', which he obtained from methæmoglobin exposed to strong light. He also recorded the absorption spectrum of this derivative, which differed markedly from those of methæmoglobin and hæmoglobin. Bock's 'photomethæmoglobin' was re-examined by Haldane[3], who identified it as the cyanmethæmoglobin compound discovered and well described by Kobert[4]. Cyanide, according to Haldane, originated in Bock's experiments from the photodecomposition of ferricyanide present in his solution of methæmoglobin when it was exposed to light. Haldane[3], being unaware of the fact that the light-sensitivity of ferricyanide had already been recorded before, carried out some interesting experiments on this subject. Thus, on treating methæmoglobin in the dark with a solution of ferricyanide previously exposed to light, Bock's 'photomethæmoglobin' was immediately obtained, and was indistinguishable from cyanmethæmoglobin formed by treating methæmoglobin with cyanide. Haldane's conclusion as to the nature of 'photomethæmoglobin' was corroborated by Zeynek[5].

On several occasions in the course of recent experiments, I have observed the formation of the cyanferriperoxidase complex during spectroscopic examinations of samples of pure peroxidase treated with ferri- or ferro-cyanide solutions freshly prepared, but not protected from light. These experiments suggest that if a hæmoprotein compound, treated with ferri- or ferro-cyanide solutions, shows certain changes in its absorption spectrum, or in some of its other properties, which cannot be accounted for by simple oxidation or reduction reactions, it is advisable to compare the derivative thus obtained with the same hæmoprotein solution treated with different concentrations of cyanide.

A New Technique of Chromatography and Ionophoresis on Ion-exchange Paper. Application to Separation of Barbiturate, Salicylate, Acetophenetidin and *p*-Acetylaminophenol

IN a previous communication, we[1] showed that a mixture of salicylate, barbiturate, and acetophenetidin could be separated by a combination of chromatography and ionophoresis on a sheet of cellulosic anion-exchanger.

According to Stewart and Stolman[2], a major metabolite of acetophenetidin in the human body is *p*-acetylaminophenol. When *p*-acetylaminophenol is subjected to chromatography on Whatman *DE*20 ion-exchange paper, it moves at approximately the same speed as phenobarbitone, so that a mixture of these two compounds is not resolved. However, if the paper is now subjected to ionophoresis, the *p*-acetylaminophenol moves more slowly than the barbiturate. This means that, by using our new technique[1] of chromatography and ionophoresis on ion-exchange paper, it is possible to obtain complete resolution of a mixture of salicylate, phenobarbitone, acetophenetidin and *p*-acetylaminophenol. The results are illustrated in Fig. 1.

It also has been observed that when the wet sheet (following ionophoresis) is viewed in the light from a mercury-vapour lamp emitting radiation at 2,537 Å., the *p*-acetylaminophenol shows up as a dark purple absorbing spot. However, after the paper has dried, the spot shows a very light blue fluorescence when viewed in the ultra-violet light. This phenomenon is observed when only *p*-acetylaminophenol is present. It occurs following chromatography in dilute ammonia solution, but not when applied to the paper without ammonia treatment. Hence, the final dried sheet when examined in ultra-violet light shows the pale-blue fluorescent spot of *p*-acetylaminophenol differentiated quite clearly from the faster moving and dark purple absorbing spot of phenobarbitone.

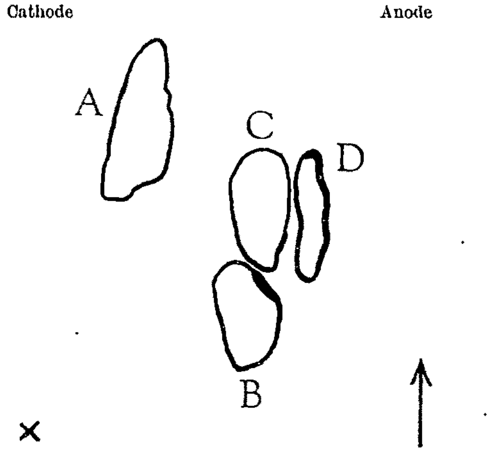

Fig. 1. Chromatography in 0·2 *N* ammonia (15 min.) followed by ionophoresis in 0·2 *N* ammonia (60 min.; constant current, 5 m.amp.; initial voltage, 250 V.) of a mixture of acetophenetidin (*A*), salicylate (*B*), *p*-acetylaminophenol (*C*) and phenobarbitone (*D*). Arrow indicates direction of ascending solvent-flow during chromatography; mixture applied at *X*

The chromatography separation takes about 15 min., ionophoresis about 1 hr. 0·2 *N* ammonia solution is used as 'solvent'.

A full account of these procedures will be published elsewhere.

Isolation of Beta-Alanine from *Iris tingitana* (var. Wedgewood)

BETA-ALANINE has often been reported (for example, Hulme and Arthington[1]) in plants on the basis of chromatographic evidence and is now considered to be a common plant constituent[2].

Virtanen and Laine[3] isolated beta-alanine from the root nodule bacteria of peas, but there is no published report of the isolation of beta-alanine from higher plants. In the process of isolating beta-amino*iso*butyric acid from iris bulbs[4], beta-alanine has been obtained in crystalline form and characterized by classical physical and chemical methods.

Beta-alanine and beta-amino*iso*butyric acid were separated from the other neutral amino-acids in the 80 per cent ethanol extract of iris bulbs (45 kgm.) on 'Dowex I' in the salt form[5]. The two beta amino-acids were separated from each other by chromatography with *n*-butanol/methanol/water (2 : 2 : 1) on a paper roll. Final purification was accomplished by crystallization from aqueous ethanol, resulting in 300 mgm. of material. Quantitative analysis of an extract of a different sample of Wedgewood iris resulted in a value of 0·045 µmole of beta-alanine per gm. of tissue fresh weight. The elemental analysis of the isolated material was 40·5 C, 7·93 H and 15·7 per cent N (theoretical values for beta-alanine are 40·3 C, 8·15 H and 15·6 per cent N). The infra-red spectrum of the isolated material in a potassium bromide disk was identical with that of authentic beta-alanine. The iris amino-acid co-chromatographed with beta-alanine in phenol/water (8 : 3), butanol/acetic acid/water (9 : 1 : 2·5) and *n*-butanol/methanol/water (2 : 2 : 1).

The 2,4-dinitrophenyl derivatives of the isolate and authentic beta-alanine were prepared by Levy's method[6]. After several recrystallizations from 95 per cent ethanol, the derivatives of the isolated and synthetic amino-acids melted at 146–147° C. (uncorrected). A mixed melting point of 146–147° C. was observed. Co-chromatography of the two derivatives in Levy's solvent system produced no separation.

Possible Role of Nucleopeptides in Protein Biosynthesis

WE have reported on the isolation of nucleopeptides from guinea pig liver[1]. Further work[2,3] has revealed that these compounds were oligonucleotides combined with various peptides containing more than ten amino-acids. Steinberg *et al.*[4] have isolated some compounds of similar kind from rat kidney and liver, as well as from rabbit liver.

This communication presents some results concerning nucleopeptide biosynthesis within a cell-free system, as well as their incorporation into protein.

Guinea pigs were used for experiments. The nucleopeptide synthesis was carried out by a method identical with that applied for protein biosynthesis *in vitro*. The mixture composition was that described under Fig. 2, the only difference being that in this experiment 1 ml. of the mixture contained, instead of nucleopeptides, 0·66 μc. of L-glutamate, 0·66 μc. of L-aspartate, 0·66 μc. of L-arginine and 0·3 mgm. of each of the twenty various non-radioactive L-amino-acids ; the radioactive ones just mentioned were omitted. One-half of this mixture was sampled at the beginning of the experiment and saturated with solid ammonium sulphate. The other half was incubated at 37° for 20 min., then treated with ammonium sulphate in the same manner. Nucleopeptides were isolated from these solutions by means of ethanol according to the procedure described in ref. 1. The residue obtained, after removal of ethanol, was eluted with acidified acetone (0·4 ml. of 1 *N* hydrochloric acid per 10 ml. of acetone), transferred on strips of Whatman No. 1 paper (5 × 57 cm.) and electrophoresis was carried out in the Markham and Smith apparatus[5]. The applied conditions were : ammonium acetate buffer 0·08 *M*, *p*H 5·0, potential gradient 50 V./cm., temperature 10–15°, and time 2 hr. The material examined was separated into three fractions visible in ultra-violet light and moving towards the cathode. The control test showed that these fractions did not contain free glutamate at all and neither aspartate nor arginine. The fractions were excised, eluted with 0·01 *N* hydrochloric acid, concentrated by evaporation and chromatographed within the solvent system containing butanol–acetic acid–water (4 : 1 : 5). The chromatography of radioactive glutamate, aspartate and arginine was performed under identical conditions. The photograph of the chromatogram was then taken in ultra-violet light and autoradiographed for 6 weeks (Fig. 1). The darkened areas of the autoradiograph corresponded to spots in the picture taken in ultra-violet light, although some spots showing absorption at 260 mμ did not contain any radioactivity. The paper was then sprayed with 0·5 *N* salt-free hydroxylamine and dried in air. After treatment with acidified ferric chloride some pink-brown spots arose which indicated the presence of hydroxamic acids. They corresponded in their localization to the spots found in the picture taken in ultra-violet light, as well as to the darkened areas of the autoradiogram. The spots showing high radioactivity were excised, eluted with 0·01 *N* hydrochloric acid and the eluate hydrolysed with 6 *N* hydrochloric acid for 16 hr. at 105°. Then hydrochloric acid was evaporated, iron removed with ammonium hydroxide, the residue chromatographed, as described, and the chromatogram developed with ninhydrin. Three to seven spots were found. The spots corresponding to glutamate, aspartate and to arginine were excised and their radioactivity was recorded.

Experiments were undertaken afterwards to establish whether the peptide part of nucleopeptides might

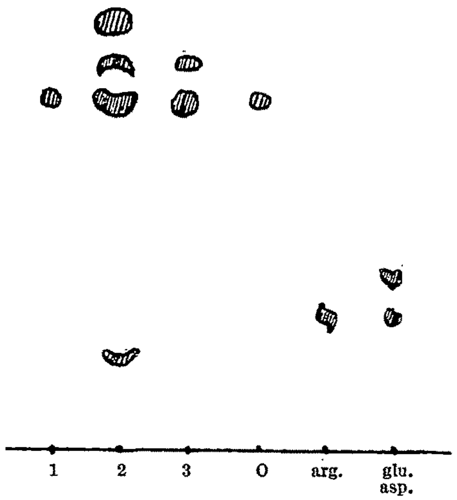

Fig. 1. The autoradiographed chromatogram of the nucleopeptides obtained *in vitro* in the presence of carbon-14 labelled glutamate, aspartate and arginine, as well as that of the standard amino-acids. 1, 2 and 3 are fractions of nucleopeptides after incubation and electrophoresis; O, before incubation

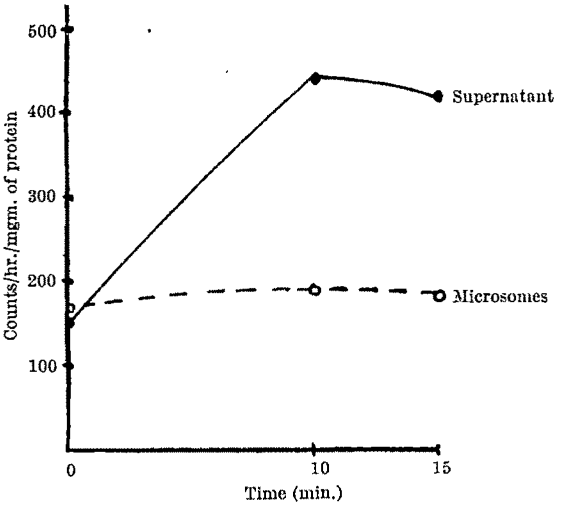

Fig. 2. Incorporation of nucleopeptides into proteins within a cell-free system. Incubation mixture contained in 1 ml. : 12 mgm. of the guinea pig liver microsomal protein (obtained in 0·25 *M* sucrose between 10,000*g* and 40,000*g*), 5·6 mgm. of the *p*H 5 enzymes from the supernatant at 40,000*g*, 0·58 mgm. of ATP (potassium), 4·4 mgm. of potassium chloride, 0·12 mgm. of $MgCl_2$, 4·6 mgm. of phosphocreatine (sodium), 0·3 mgm. of the phosphocreatine kinase, 0·07 mgm. of GTP ($2Na.2H_2O$) ^{14}C-nucleopeptides, 3,200 c.p.m. Components were dissolved in 0·1 *M tris* buffer, *p*H 7·5. Samples for the radioactivity measurement were diluted with a threefold volume of 0·25 *M* sucrose and centrifuged at 40,000*g*

be incorporated into protein when preparations for synthesizing protein *in vitro* were applied. Radioactive nucleopeptides were derived from the liver of a guinea pig which had been injected into the heart with carbon-14 labelled glutamate, aspartate and arginine at doses of 45 μc./kgm. body-weight. The animal was killed by decapitation 3 min. after injection and nucleopeptides were isolated[1,2], the free radioactive amino-acids being removed by means of paper electrophoresis as described. The nucleopeptides formed *in vivo* eluted from electropherograms were added to the system for synthesizing protein *in vitro*. Then the radioactivity of protein was measured in microsomes as well as in the supernatant after centrifugation at 40,000*g*. The purification of proteins for this estimation was carried out according to the commonly applied procedure[6]. The radioactivity was measured with an end window Geiger–Müller counter. Fig. 2 shows that radioactivity appears mainly in the supernatant proteins, whereas its incorporation into microsomes is considerably less.

Our experiments prove that nucleopeptides are formed in the system for synthesizing protein *in vitro* and it seems that they participate in protein biosynthesis.

Details of these investigations will be published in *Acta Biochimica Polonica*.

Configuration of the 6-Hydroxyl Group in Phenolic Steroids

DURING recent years reports from various laboratories have indicated that phenolic steroids substituted at C_6 may have biological significance. Thus, Mueller and Rumney[1] provided evidence for the conversion of radioactive œstradiol-17β to 6-hydroxyœstradiol-17β by mouse liver microsomes *in vitro*. Furthermore, 6-hydroxyœstradiol-17β has been isolated as a metabolite after incubation of œstradiol-17β with slices of rat liver[2] and human fœtal liver[3]. Bush *et al.*[4] detected 6-hydroxyœstradiol-17β in the follicular fluid of the mare, and Marrian[5] reported on the isolation of a new Kober chromogen (*KC–6B*) which appears to be identical with a 6-hydroxyœstrone.

The 6-hydroxyœstradiol-17β which served as a reference compound in this work was obtained by borohydride reduction of 6-oxo-œstradiol-17β [6]. Wintersteiner and Moore[6] have given reasons for believing that the 6-hydroxyl group thus formed may have a quasi-equatorial configuration; accordingly the compound was provisionally designated as 6'α'-hydroxyœstradiol-17β.

There seemed to exist various possibilities of obtaining more decisive configurational evidence, one of which involved the biological aromatization of 6α- and 6β-hydroxylated C_{19}-steroids to the corresponding phenolic steroids. After preliminary experiments it was decided to employ the aromatizing enzyme preparation from human placenta which has been shown by Ryan[7] to be most efficient in converting C_{19}-steroids to C_{18}-steroids. The investigation of the problem necessitated a paper chromatographic system for the separation of the two epimeric 6-hydroxyœstradiols. Both compounds are easily separated from each other in the system formamide/chloroform (5): ethyl acetate (1), the 'α'-epimer (formed by reduction of 6-oxo-œstradiol-17β with sodium borohydride[6]) travelling faster than the 'β'-epimer (formed by catalytic reduction of 6-oxo-œstradiol-17β with platinum oxide in ethanol[6]).

The incubation of 6α-hydroxy-Δ^4-androstene-3.17-dione with the 10,000*g* supernatant fraction of human placenta homogenate in the presence of adenosine triphosphate and diphosphopyridine nucleotide resulted in the formation of a phenolic metabolite which had the same R_F value as 6'α'-hydroxyœstrone[8] in the system formamide/chloroform. After reduction of the 17-oxo-group with sodium borohydride and subsequent chromatography in the formamide/chloroform-ethyl acetate system the substance showed the same mobility (14·7 cm./14 hr.) as the 6-hydroxyœstradiol-17β provisionally designated by Wintersteiner and Moore[6] as the 6 'α'-compound. When 6β-hydroxy-Δ^4-androstene-3.17-dione was incubated with the placental enzyme a phenolic metabolite was formed having a similar R_F value to 6'β'-hydroxyœstrone in the system formamide/chloroform. Reduction with sodium borohydride yielded a substance which on chromatography in the system formamide/chloroform-ethyl acetate showed the same mobility (12·8 cm./14 hr.) as the 6-hydroxyœstradiol-17β provisionally designated as the 6'β'-compound. After elution from the paper the material was acetylated and subjected to sublimation under atmospheric pressure. The melting point of the crystals (175–177°) was identical with that of authentic 6'β'-hydroxyœstradiol-17β-triacetate. An additional experiment was carried out with 6β-hydroxy-19-nor-testosterone. The phenolic substance obtained after incubation of this steroid with the placental enzyme showed the same mobility in the formamide/chloroform-ethyl acetate system as 6‘β’-hydroxyœstradiol-17β. By control experiments, the possibility was excluded that epimerization or oxido-reduction of the 6-hydroxyl groups in the neutral and phenolic steroids had occurred during incubation with the aromatizing enzyme.

Since the configuration of the 6-hydroxyl groups in neutral steroids[9] is well established, the experiments reported here now permit the definite assignment of configurations to the two epimeric 6-hydroxyœstradiols. The 6-hydroxyœstradiol-17β which results from reduction of the 6-oxo group with sodium borohydride is assigned the 6α-configuration, whereas the other epimer which is formed by catalytic reduction with platinum oxide has the 6β-configuration.

Full experimental details will be published elsewhere. We wish to express our thanks to Prof. M. Ehrenstein, University of Pennsylvania, Philadelphia, for a generous gift of 6α- and 6β-hydroxy-Δ^4-androstene-3.17-dione, and to Dr. A. Szpilfogel, N.V. Organon, Oss, for a sample of 6β-hydroxy-19-nortestosterone. We are also indebted to Dr. G. F. Marrian, Imperial Cancer Research Fund, London, and to Prof. M. Ehrenstein for reading the manuscript and for their helpful suggestions.

Determination of Enzyme Activity by a Linear Measurement

The determination of the activity of proteolytic enzymes usually requires chemical analysis. A substrate, which can be either natural or synthetic, is being hydrolysed by the enzyme under specified conditions, and after a certain time the concentration of either the products or the remaining substrate is determined analytically. These methods are generally rather cumbersome. Furthermore, it is essential to perform the reaction under conditions such that only a small percentage of the substrate is transformed, so that the effect of the products on the reaction-rate should be negligible. This again leads to some analytical difficulties.

Let us suppose that a natural polymeric substance can be prepared in a homogeneous hydrated form, such as a gel, and then it can be cross-linked by some chemical means. A small number of cross-links, while leaving the chemical nature of the substrate virtually unchanged, will render the system insoluble, and relatively rigid. The matrix of the cross-linked substance may permit the penetration of small molecules or ions, but will be impenetrable to macromolecules, such as enzymes. Consequently, the action of the enzyme will be restricted entirely to the surface. Since the enzymatic breakdown products are usually soluble in aqueous media, these products will constantly be removed, and a fresh surface exposed to the enzyme.

If the enzyme-substrate interaction is restricted to the surface of the substrate, it is reasonable to assume that the reaction-rate will be proportional to the exposed surface area. Provided the substrate is homogeneous the reaction-rate will appear as a rate of change of volume of the substrate. These considerations can be expressed in the following relationship: $\frac{dV}{dt} = -k\,A$, where V is the volume of the substrate, t is the time, and A is the exposed surface area.

Denoting by dx the thickness of the layer of cross-linked substrate solubilized during time dt, then $dV = A dx$ or $\frac{dx}{dt} = -k$. In other words, the rate of change of any linear dimension perpendicular to the surface is constant. To determine k one measures a linear dimension perpendicular to the surface, for example, an edge of a cube, and plots the change of this length against time. A straight line should result, the slope of which is k. Since the concentration and the degree of cross-linking of the substrate are kept constant, different slopes will correspond to different enzyme activities. Measurement of the slope thus furnishes a means to determine enzyme activities.

The above principle has been applied successfully to the case of a number of proteolytic enzymes. A slightly modified gelatin was used as substrate, which is being manufactured by Schwarz BioResearch, Inc., under the trade name of ‘Thiogel’. ‘Thiogel’ differs from ordinary gelatin in that it has a few homocysteine residues attached to the chain through peptide bonds with the lysine ε-amino groups. By virtue of this, ‘Thiogel’ has approximately 10 sulphydryl groups per 100,000 molecular weight. Oxidation of these sulphydryls to disulphide groups provides a convenient way to cross-link the polymer. ‘Thiogel’ gels can be cross-linked, for example, by atmospheric oxygen at slightly alkaline *p*H values.

The properties of cross-linked ‘Thiogel’ gels make them well suited for enzyme studies. These gels are rigid, unmeltable and can be cut into convenient geometric shapes. The chemical characteristics of gelatin are fully preserved. The equilibrium volume of the gel changes only very slightly with temperature, *p*H or ionic strength of the medium. For example, the linear expansion of the gel is only about 4 per cent when the temperature is raised from 4° C. to 40° C. The gel represents a protein in a highly hydrated form, and due to its high water content (94 per cent) it is freely permeable to small molecules and ions, such as the hydronium ion, yet completely impermeable to macromolecules, such as enzymes.

Cross-linked ‘Thiogel’ gel of about 6·5 per cent concentration has been prepared and cut into cubes of about 2 ml. volume. These cubes can be stored under water at room temperature, if some preservative, for example a few drops of chloroform, is added to the water. Before use a cube is immersed in about 200 ml. buffered solution and equilibrated for 20–30 min. at the temperature and *p*H of the determination. After this the distance between two parallel planes of the cube is measured with a micrometer. This initial

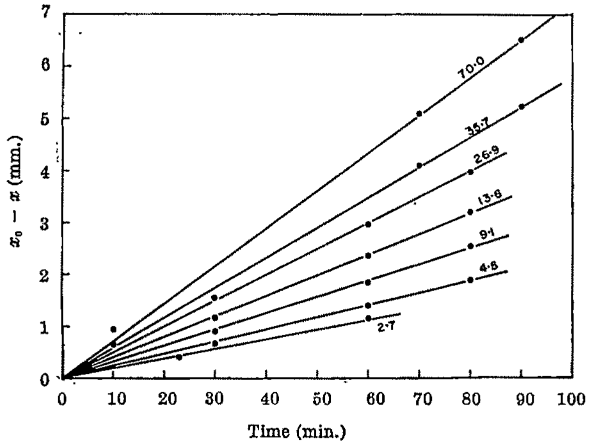

Fig. 1. Crystalline trypsin (pH 7·6, 36° C.)

distance was designated as x_0. At zero time a known amount of enzyme solution is added, and constant stirring applied. At regular intervals the cube is removed from the reaction mixture, rinsed with water to stop the reaction, and the distance x between the two parallel planes is again measured with the micrometer. After each measurement the cube is put back into the solution and the reaction continues. When plotting x_0–x against time, good linearity is generally obtained, so the slope can easily be determined and expressed in mm./hr. Sometimes at low enzyme concentrations a short induction period could be observed. In such cases it is advisable to determine x_0 about 10–20 min. after the addition of the enzyme.

Results obtained with crystalline trypsin are illustrated in Fig. 1. The trypsin concentrations (in mgm./l.) employed are given on the lines. All determinations were made at $36 \pm 0{\cdot}5°$ C. and at pH 7·6. The crystalline trypsin was prepared by Worthington Biochemical Corp., and its activity assayed about 8,500 units per mgm. determined with N-benzoyl arginine ethyl ester as substrate. Good linearity of $x_0 - x$ versus time was observed for at least 90 min. The slopes were reproducible to about 5 per cent. The magnitude of the slope is not proportional to the enzyme concentration, but follows the relationship: $\frac{x_0 - x}{t} = 0{\cdot}74\ c^{0{\cdot}427}$, where x is the distance in mm., t is the time in hours, and c is the trypsin concentration in mgm. per litre.

Other proteolytic enzymes are also being investigated using cross-linked 'Thiogel' as a substrate. Activated papain solubilizes the substrate readily. The change in linear dimension is proportional to time for about an hour. The slope is again proportional to a fractional power of the enzyme concentration. The action of crystalline pepsin and α-chymotrypsin was also studied, and it has been found that the rate of solubilization of cross-linked 'Thiogel' by these enzymes is lower by orders of magnitude as compared to the rate with trypsin. Thus the determination of the activity of trypsin can be performed in the presence of chymotrypsin.

The principal advantages of our method are that: (1) simple distance measurements are used instead of chemical analyses; (2) the enzyme–substrate interaction can be arrested merely by physical removal of the cross-linked gel from the solution; (3) the reaction can proceed over a long period of time without the reaction products having any effect on the rate since the region near the surface of the substrate may be continuously renewed. The sensitivity of our method depends on the precision of the distance measurement. The measurement need be made only over a short period of time if the substrate is a very thin sheet and one is observing the time of complete dissolution of the film. In Nature, proteases act on the surface of insoluble substrates and hence our system perhaps more closely resembles the natural condition than that with soluble protein substrates. When the cross-linked gel is removed from the enzyme solution, rinsed with water, and placed in a fresh buffer solution the dissolution of the substrate continues but at a progressively slower rate. In this manner the rate constant for the enzyme–substrate complex can be studied without the presence of free enzyme.

Our method should be applicable to other enzyme and substrate combinations. All that is required is that the enzyme be capable of cleaving either the polymer chain or the cross-linking bond of the hydrated cross-linked polymer substrate.

Inhibition of Proteolytic Enzymes by Decarboxylated Amino-Acid Derivatives. Effect of Toluenesulphonyl(Tosyl)agmatine (4-Toluenesulphonamidobutylguanidine) on Thrombin and Trypsin

PROTEOLYTIC enzymes are known to catalyse the hydrolysis of specific amino-acid esters and amides[1]. Specificity is usually determined by the side-chain of the amino-acid contributing the carbonyl function to the bond being split, and, for several reasons, it may be inferred that this ester or amide bond lends very little to the initial binding of the substrate to the enzyme. Thus we suggest that derivatives of specific decarboxylated amino-acids would act as good competitive inhibitors of these enzymes. Since these derivatives would not be subjected to simultaneous hydrolysis, the effect would be longer lasting than that obtained with competing substrates.

One can readily construct a list of decarboxylated amino-acids which, when N-(amino) acylated, would be potential inhibitors for a number of enzymes. For example:

(1) Agmatine for thrombin, trypsin, plasmin and papain.

(2) 1,5-diaminopentane for trypsin and plasmin.

(3) 2-phenylethylamine or tyramine for chymotrypsin and pepsin.

(4) β-alanine or γ-aminobutyric acid for pepsin.

This list could, of course, be extended to include other enzymes with known specificities.

Thrombin (prepared by Rasmussen's method[2]) and trypsin (Worthington) were the enzymes chosen to test these ideas, and the kinetics of the hydrolysis of N$^{\alpha}$-tosyl-L-arginine methyl ester (L-TAMe)[3] were studied with the use of a pH-stat (pH 7·7; μ, 0·069; 37°). Tosylagmatine (m.p. 178°) was synthesized and tested for inhibitory activity. The latter compound inhibited the ester hydrolysis by both enzymes in a competitive manner, with the results summarized in Table 1.

Table 1. TOSYLAGMATINE INHIBITION OF L-TAME HYDROLYSIS

Enzyme	Inverse Michaelis constant l./mole	K_I (inhibition constant) l./mole
Thrombin	$1 \cdot 79 \times 10^3$	$7 \cdot 6 \times 10$
Trypsin	$2 \cdot 78 \times 10^3$	$2 \cdot 9 \times 10^2$

The inhibitory effect of tosylagmatine on thrombin was also examined by the independent technique of measuring *p*-nitrophenol production from the substrate carbobenzoxyglycine *p*-nitrophenyl ester[4]. Tosylagmatine again proved to be a competitive inhibitor, $K_I = 8 \cdot 12 \times 10$ l./mole (at μ 0·133; *p*H 7·5; 38·4°). Furthermore, this compound effectively inhibited clotting in the thrombin-fibrinogen system, and it also greatly delayed the clotting time of whole plasma after recalcification.

One may conclude that, in spite of the fact that optical activity is lost by decarboxylation, derivatives of decarboxylated amino-acids retain most of the required characteristics of fit to the enzyme surface to classify them as competitive inhibitors. We have reasons for believing that modifications to the acylating group added to the decarboxylated amino-acids will yield even better inhibitors.

PHYSIOLOGY

Effect of Iproniazid on the Antileukæmic Action of Reserpine

AN earlier communication reported the ability of reserpine to exert an antitumour effect[1]. This effect has been, in general, associated with the depressant action of the drug on the central nervous system[1-3]. Treatment with reserpine produced a significant increase in the survival-time of mice carrying advanced lymphoid leukæmia (*L*1210) and caused regression of the local tumour which develops at the inoculation site[1]. Robison *et al.* have made similar observations[2]. Belkin observed that reserpine and chlorpromazine inhibited the growth of the solid tumour, sarcoma 37 [3]. Cranston[4], on the other hand, failed to demonstrate inhibitory action on recent transplants of spontaneous mammary adenocarcinoma in mice with reserpine, chlorpromazine, promazine or promethazine. Chorazy[5] found no inhibitory effect of chlorpromazine on Crocker sarcoma or Ehrlich carcinoma in mice.

Shore and Brodie[6] showed that, following pretreatment of rabbits with iproniazid (a monoamine oxidase inhibitor), reserpine administration resulted in excitatory and sympathomimetic responses. However, when iproniazid was administered after reserpine, it failed to alter the depressant effects on the central nervous system[6,7]. In an effort to dissociate the central depression induced by reserpine from its antitumour activity, experiments were conducted to determine the effect of prior administration of iproniazid on the antileukæmic effectiveness of reserpine in mice.

The reversal by iproniazid of the action of reserpine against advanced leukæmia is illustrated in Fig. 1. In this experiment daily injection of iproniazid (200 mgm./kgm.) was begun 6 days after the inoculation of mice with leukæmic cells. Reserpine was administered on day 8. The median survival-time of control leukæmic mice was eleven days. The median survival-time was increased progressively by increasing the dose of reserpine, reaching a maximum of 17 days at a dose of 12·5 mgm./kgm. of the drug. Daily injection of iproniazid reduced the median survival-time to that of the controls over the entire dose range of reserpine. Mice receiving iproniazid alone had the same median survival-time as the controls (11 days).

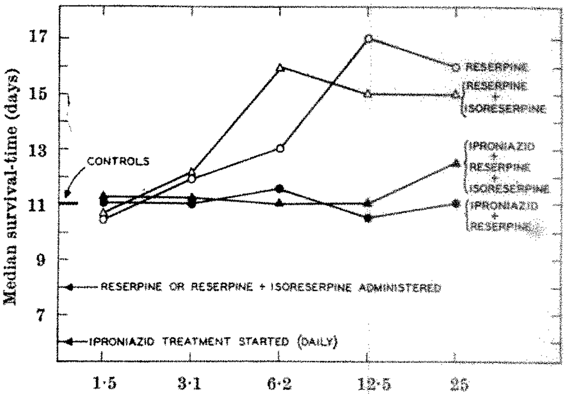

Fig. 1. The general methods have been previously described by Goldin *et al.* (refs. 9 and 10). Experiments were conducted in hybrid male mice ($(BALB/c\ An \times DBA/2J)F_1$) 8–10 weeks old and 20–25 gm. in body-weight. They were inoculated in the right hind leg with 0·1 ml. of a suspension of *L*1210 leukæmic cells. Treatment of advanced leukæmia was initiated when the local tumour reached a diameter of 9–12 mm., at which time the disease is systemic and can be transmitted by the blood. Iproniazid (200 mgm./kgm.) was administered intraperitoneally daily from day 6 until death. *Iso*reserpine (50 mgm./kgm.) was given subcutaneously on day 8. Reserpine at the doses noted was administered subcutaneously on day 8, 30 min. after the *iso*reserpine. Ten mice per group

The activity of 3-*iso*reserpine, a stereoisomer of reserpine, was of particular interest, since this compound is known to be devoid of depressant effects on the central nervous system. (One preparation of 3-*iso*reserpine produced marked central nervous system depression and antileukæmic activity similar to that seen with an effective dose of reserpine[1]. This preparation was later shown to be contaminated with 5 per cent reserpine.) The combination of 3-*iso*reserpine (50 mgm./kgm.) and reserpine (6·2 mgm./kgm.) prolonged survival-time three days over that observed with reserpine alone at this dose. This is suggestive of a potentiating effect by *iso*reserpine. This dose of *iso*reserpine alone did not produce depression of the central nervous system or increase the survival-time of mice with acute leukæmia. (This potentiating effect by 3-*iso*reserpine has been seen in several experiments. In addition, potentiation of reserpine action by 3-*iso*reserpine was also demonstrated in the prolongation of pentobarbital-induced anæsthesia. In one experiment, reserpine alone (2·5 mgm./kgm.) prolonged pentobarbital (70 mgm./kgm.) anæsthesia approximately four times, while in combination with 3-*iso*-reserpine (50 mgm./kgm.), anæsthesia was extended six times[8]. Reserpine and 3-*iso*reserpine were injected subcutaneously four hours prior to intraperitoneal pentobarbital.) However, when the same dose of 3-*iso*reserpine (50 mgm./kgm.) was used in combination with larger doses of reserpine, no further enhancement of survival-time was obtained. Injection of iproniazid decreased the median survival-time to that of the controls up to a dose of 12·5 mgm./kgm. of reserpine with *iso*reserpine (50 mgm./kgm.). At the highest dose (25 mgm./kgm. reserpine with 50 mgm./kgm. *iso*reserpine), the median survival-time of 15 days was reduced by iproniazid to 12·5 days.

Iproniazid appeared to reverse the depressant action both of reserpine and of reserpine in combination with 3-*iso*reserpine. Iproniazid also prevented the loss of body-weight and inhibition of local tumour growth. Only in the group receiving 25 mgm./kgm. of reserpine and 50 mgm./kgm. of 3-*iso*reserpine with iproniazid was depression of the central nervous system evident. The reversal of reserpine action by iproniazid was also demonstrated in other experiments, including one in which the drugs were administered early (3 days after inoculation with leukæmic cells) in the course of the disease.

The experiments reported in this communication failed to demonstrate a dissociation of the depressant action of reserpine on the central nervous system from the ability of reserpine to inhibit leukæmic tumour growth. Therefore, it remains to be determined whether this correlation is indicative of a non-specific host-mediated antileukæmic effect or whether there is a specific antitumour action of reserpine.

We wish to thank Ciba Pharmaceutical Products, Inc., for the reserpine ('Serpasil') and 3-*iso*reserpine used in this study and Hoffmann-LaRoche, Inc., for the iproniazid ('Marsilid phosphate').

This work was supported in part by a grant from the National Institute of Mental Health, National Institutes of Health, United States Public Health Service (*M*–2338C1), and a grant-in-aid from Hoffmann-LaRoche, Inc.

Influence of Gamma-Aminobutyric Acid on the Acetylcholine Responses of the denervated Rat-Diaphragm Preparation

THE literature on the actions of γ-aminobutyric acid was reviewed comprehensively by Elliott and Jasper in 1959 [1]. Several investigators have demonstrated that it and related substances are normal products of brain metabolism, and that it has an important action on brain function as well as on certain peripheral nerve structures[2]. It is known to reverse the surface-negative post-synaptic potentials of the apical dendrites of the cerebral cortex[3] and also blocks transcallosal conduction when injected into the internal carotid artery[4]. The exact mechanisms by which these effects are produced are still unknown. Hence work on the influence of γ-aminobutyric acid on the acetylcholine responses of the denervated rat's diaphragm was undertaken.

Denervation was carried out on the right side by section of the roots of the phrenic nerve and the preparations were used at variable times after the denervation.

A triangular strip of the right half of the diaphragm was dissected carefully and fixed by means of threads to a special electrode holder made of 'Perspex'. The whole preparation was immersed in a bath containing Krebs–Henseleit solution[5] and oxygenated by passing very fine bubbles of 95 per cent oxygen and 5 per cent carbon dioxide. The temperature of the bath was maintained at 37° C. The muscle was connected by its tendinous portion to a lever, and the activity of the muscle was recorded on a slowly moving smoked drum.

The muscle could be stimulated either electrically using a physiological stimulator (Ritchie–Sneath) or chemically using acetylcholine. The complete details of the technique are published in my thesis on the denervated rat-diaphragm preparation published in 1951 (ref. 5).

Several experiments were conducted and the results were accepted only after each new finding could be repeated several times. The following results were obtained:

(1) 400–1,000 µgm. γ-aminobutyric acid had no action on the responses of the innervated rat's diaphragm, when stimulated by maximal stimuli through its nerve (rate 4–5/min.). This work confirms that of Hobbiger[2].

(2) 1,000 µgm. of the drug has no action on the responses of the denervated rat-diaphragm prepara-

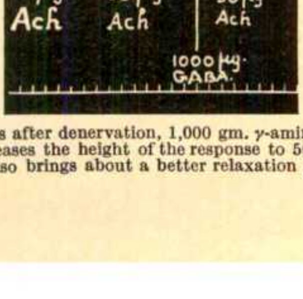

Fig. 1. 7 days after denervation, 1,000 gm. γ-aminobutyric acid not only increases the height of the response to 50 µgm. acetylcholine but also brings about a better relaxation of the muscle

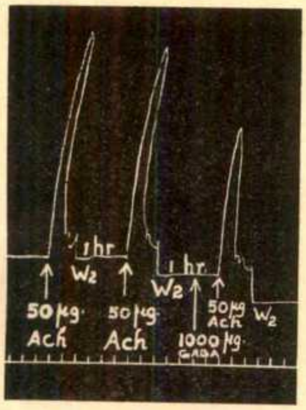

Fig. 2. 8 days after denervation, 1,000 gm. γ-aminobutyric acid not only reduces the height of the response to 50 μgm. acetylcholine but also brings about better relaxation of the muscle

tion (8–10 days after denervation) when stimulated by maximal stimuli at a rate of 4–5 per min.

(3) In my thesis on the denervated rat diaphragm preparation[5], I observed that the first noticeable response to a test dose of acetylcholine (50 μgm.) was obtained on the third or fourth day after nerve section. The sensitivity thereafter increased progressively and was fairly well established by the second week. This state was maintained up to the fifth to sixth week, and then there was a steady decline to almost nothing by the third month after denervation.

As the sensitivity of the denervated preparation alters with time, the influence of γ-aminobutyric acid on the acetylcholine responses was studied with preparations 7, 8, 9 and 10 days after denervation. It was noticed that 1,000 μgm. produced two main changes to the responses of the denervated preparation to 50 μgm. of acetylcholine: (*a*) An alteration in the height of the contracture. The height was always increased in 7-day preparations and diminished in 8-day preparations (Figs. 1 and 2). (*b*) A more complete relaxation of the muscle was noticed in both preparations. It was also found that 1,000 μgm. γ-aminobutyric acid had variable actions on the acetylcholine responses of 9-day-old preparations and no influence whatsoever on 10-day-old preparations.

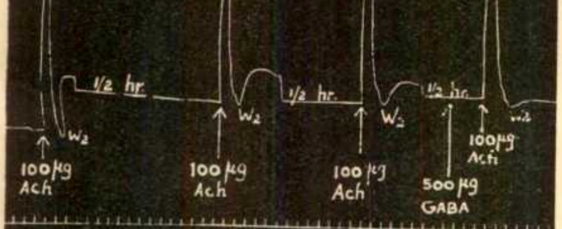

Fig. 3. Responses of a denervated preparation (8 days) when immersed in Krebs–Henseleit solution containing one quarter the normal concentration of potassium chloride. 500 μgm. γ-aminobutyric acid is found to bring about a better relaxation of the muscle after the same dose of acetylcholine (100 μgm.)

(4) It was noticed that 500 μgm. γ-aminobutyric acid abolished the second contracture that occurs when 100 μgm. of acetylcholine was introduced into a bath containing a denervated preparation with a potassium concentration one quarter that found in normal Krebs solution (normal Krebs has 5·52 gm. potassium chloride/15 litres, Fig. 3).

(5) 1,000 μgm. γ-aminobutyric acid had no influence on the contracture produced by 50 μgm. adrenaline on the denervated rat-diaphragm preparation.

Effect of Duodenal Administration of Highly Unsaturated Fatty Acids on Composition of Ruminant Depot Fat

Although linolenic acid is the main fatty acid of pasture lipids, the fats of pasture-fed ruminants contain little if any of this constituent[1]. Also, feeding large quantities of highly unsaturated oils to ruminants has had no perceptible effect on the unsaturation of their depot fats[2]. Various workers[3–5] have shown that micro-organisms in the rumen hydrogenate dietary unsaturated fatty acids, and this has been presumed to explain the low content of highly unsaturated fatty acids in the depot fats of ruminants.

To test whether this explanation was correct the rumen micro-organisms have been by-passed and dietary lipids rich in linoleic and linolenic acids presented to the tissues by administering linseed oil through a duodenal cannula to a sheep, and the effect on the composition of the depot fat observed.

A mature Merino ewe was cannulated about 6 in. from the pylorus and fed on chaffed lucerne hay. About 40 ml. of an emulsion of 8 vol. of linseed oil and 1 vol. of bile were given each day, half in the morning and half in the evening, for six weeks. The perinephric fat was then obtained after killing and the fatty acids subjected to gas-liquid chromatography. Results are given in Table 1.

Palmitic, stearic and C_{18} monoene (oleic) contents of the fat were within the normal range, but the C_{18} diene (linoleic acid) and triene (linolenic acid) contents were greatly above the normal range of 1–2 per cent. This shows that the main fatty acid constituents—linoleic and linolenic acids—of linseed oil

Table 1. FATTY ACID COMPOSITION OF PERINEPHRIC FAT (MOLAR PER CENT)

	n-Saturated	Branched saturated	Unsaturated
C_{10}	0·20	—	—
C_{12}	trace	—	—
C_{14}	1·20	0·10	—
C_{15}	1·00	0·89	—
C_{16}	26·83	—	1·09
C_{17}	2·99	2·19	—
C_{18}	27·12	—	Monoene 18·55 Diene 7·87 Triene 9·97

are capable of being deposited in the depot fats of ruminants as in the case of non-ruminants provided they are not first subjected to the action of the rumen micro-organisms.

Thus the hypothesis mentioned here, that the differences between the depot fats of ruminants and non-ruminants arise from the hydrogenation of the unsaturated dietary fats in the rumen, receives further support.

Photomotor Reflex as an Indicator of Consciousness during Curarization

WHEN a relaxant is used in conjunction with a general anæsthetic, a new problem arises in assessment of the depth of anæsthesia: the reflexes which normally indicate returning consciousness and awareness of pain cannot appear if the patient is under the influence of a relaxant. Thus, if only reflexes involving voluntary muscle are used, it is possible, in the presence of a relaxant, for anæsthesia to lighten so that surgery is performed on a conscious paralysed patient without surgeon or anæsthetist being aware of the situation. This has been recorded more than once in human medicine, the patient having described the situation after the operation[1]. The same situation can occur in operations on animals when an anæsthetic is used in conjunction with a relaxant; but in this case the patient cannot afterwards direct attention to the mistake. Such circumstances produce problems with humanitarian and legal aspects for the veterinarian, as Finn[2] has pointed out; they also complicate the interpretation of the pain clause for research workers holding a vivisection licence.

The electroencephalograph can be used to assess depth of anæsthesia in a curarized man or animal, but it is not always available, and needs some skill in interpretation. Experiments have therefore been carried out to discover a simple method of assessing depth of consciousness in curarized dogs, the electroencephalograph being used as a criterion of the activity of the brain. Pentobarbitone sodium, thiopentone sodium and ether were used as anæsthetics, and succinylcholine chloride as the relaxant.

It was found that the photomotor reflex (change in size of pupil of eye with sudden change in light intensity), unlike the other reflexes commonly used for testing anæsthesia, gave a reliable indication of returning consciousness in the presence of a relaxant. It became positive as the dog passed from stage III (surgical anæsthesia) to stage II (excitement). Pre-medication with atropine did not invalidate the reflex, provided that the dose of atropine did not exceed 0·032 mgm./kgm. body-weight. It seems likely that this reflex would also be useful in human patients in similar circumstances. The work will be described in more detail elsewhere.

Spiral Nerve-endings (Proprioceptors) in the Human Vocal Muscle

THE problem of the proprioceptive innervation of the human vocal muscle is still controversial[1]. The presence of a proprioceptive mechanism controlling the fine adjustments of the vocal cords has been postulated by some authors; it has been rejected on theoretical grounds by others. Paulsen[2] assumes that the tension of the vocal muscle would have central control alone. A peripheral proprioceptive mechanism would be rather a hindrance for normal phonation. The same was said to be true of the extrinsic eye muscles, in which nevertheless proprioceptors have been demonstrated within the past ten years histologically as well as by electrical records[3-5].

To clear up the question, we have cut the vocal muscle of men who had shown no evidence of neurological disease during life, in longitudinal frozen sections of 40–60μ thickness. With a modification of the silver staining Bielschowsky–Gros method, we succeeded in showing spiral nerve-endings in this muscle, which may be interpreted as mechanoreceptors responding to stretch or shortening of the fibres (Fig. 1).

These spiral structures have been found to form a group of 3–5 nerve-endings occupying a small place within the motor innervation zone[6] near the free inner board of the muscle at the level of the vocal

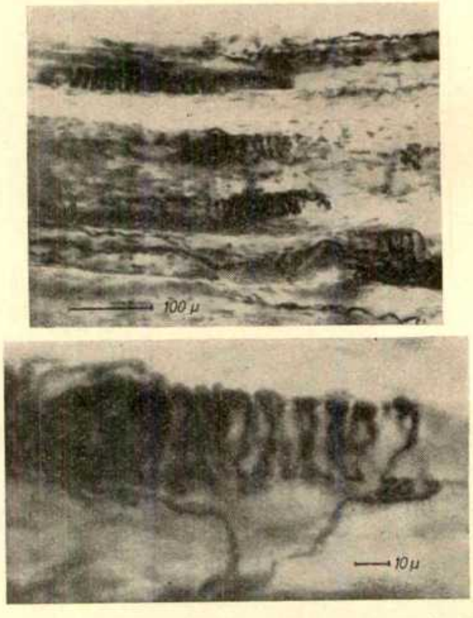

Fig. 1. Spiral nerve-endings in the human vocal muscle; silver staining. Top: Group of receptors in the small diameter muscle fibre area (inner board) of the muscle. Bottom: One receptor with higher magnitude; double spiral turns in the left part around two small muscle fibres

string. They look like the annulo-spiral endings in the equatorial region of muscle spindles. Their length varies from 100 to 200μ. The nerve fibre is coiled up around one or two small muscle fibres in steep turns. Between the spiral endings are closely packed nuclei, suggesting a region of intense metabolic activity. The size of muscle fibre varies in the vocal muscle from 10 to 60μ. The spiral nerve-endings and their associated muscle fibres lie within a region where the diameter of most of the muscle fibres does not exceed 10μ. One or two end-plates of the associated fibres which stained in some cases were found within 100μ from the spiral district. There is no histological evidence that an efferent gamma-system exists in the vocal proprioceptive mechanism. A connective tissue wrap around the spindle organ does not seem to be present.

These structures differ from the classical form of spindles described by Kühne and Ruffini. There is perhaps some relation to the spiral nerve-endings in extrinsic eye muscles of which the receptor properties have been shown[4]. The spiral ending in the vocal muscle may be a rather primitive form of proprioceptor, which is no surprise in a muscle of such particular origin (Goerttler).

The fact that these spiral nerve-endings are not encapsulated and the inner muscle fibre diameter does not differ markedly from the diameter of the surrounding muscle fibres may be the reason why they have been overlooked in transverse sections. They could relate to the recently described myotatic reflex elicited in the human vocal cord[7].

Active Transport of Foreign Pyrimidines across the Intestinal Epithelium

THE small intestine of mammals possesses at least three independent active transport processes for the absorption of organic compounds: one for monosaccharides like glucose and galactose[1]; one for L-amino-acids[2]; and one for pyrimidines like uracil and thymine[3]. These specialized absorption processes have a number of characteristics in common which distinguish them from the process of simple diffusion: the substrate is transferred against a concentration gradient; the transport systems become saturated at high concentrations of substrate; and one substrate depresses the passage of another by competing with it for the transport process.

In contrast to the natural cell substrates, most drugs and other foreign organic compounds are absorbed mainly by simple diffusion[4,5]. The intestinal epithelium behaves towards these substances as an inert, lipid-like layer, readily penetrated by lipid-soluble, undissociated molecules, and penetrated with difficulty by lipid-insoluble molecules and ions.

The present work indicates that foreign organic compounds similar in structure to a normal substrate can be absorbed by a specialized transport process. Evidence is presented that two foreign pyrimidines with anti-tumour activity, 5-fluorouracil and 5-bromouracil, are actively transported by the pyrimidine transport system of the intestine.

For the experiments, male Sprague–Dawley rats (120–130 gm.), fasted for 20 hr. but allowed free access to water, were killed by decapitation, and the upper part of the small intestine was removed. Sacs of everted intestine[6], 20 cm. long, were filled with 2 ml. of bicarbonate–saline solution[7] which contained 1 gm. of glucose per litre and various concentrations of uracil-2-^{14}C, 5-fluorouracil-2-^{14}C, or 5-bromouracil-2-^{14}C. The sacs were suspended in 15 ml. of the same fluid contained in 50-ml. beakers, and the beakers shaken in a Dubnoff metabolic shaker (90 oscillations per min.) at 37° C. in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. After 1 hr., the mucosal and serosal solutions were collected, and the concentration of pyrimidine estimated from the radioactivity of the solutions.

Evidence that the labelled compounds are not altered metabolically by the intestine was provided by paper chromatography of the pyrimidine solutions incubated with the intestine. Chromatograms developed in either *n*-butanol/acetic acid/water (20 : 6 : 17 v/v/v) or ethyl acetate saturated with 0·1 *M* acetate buffer (*p*H 5·3) revealed single radioactive spots with R_F values the same as those of the non-incubated pyrimidines chromatographed on the same sheets.

The extent of transfer of the pyrimidines across the intestinal epithelium, against a concentration gradient, is shown in Table 1. When the initial concentration of pyrimidine was 0·02 m.mol./litre, fluorouracil was transported to about the same extent as uracil, attaining a serosal/mucosal concentration ratio of 4·5; bromouracil was transported to a somewhat smaller degree, attaining a serosal/mucosal ratio of 3.

Table 1. INTESTINAL TRANSFER OF PYRIMIDINES AGAINST A CONCENTRATION GRADIENT *in vitro*

Pyrimidine	Concentration of pyrimidine (m.mol./l.)			Final, serosal to mucosal concentration ratio
	Initial, mucosal and serosal solutions	Final, mucosal solution	Final, serosal solution	
Uracil	0·020	0·012	0·056	4·7 ± 0·3*
5-Fluorouracil	0·020	0·011	0·049	4·5 ± 0·3†
5-Bromouracil	0·020	0·013	0·039	3·0 ± 0·2†

* Mean value for 27 animals ± *S.E.*
† Mean value for 8 animals ± *S.E.*

The transport process became saturated at high concentrations of the pyrimidines. For example, on raising the concentration of fluorouracil or bromouracil to 0·5 m.mol./litre, the serosal/mucosal concentration ratios declined to values approaching unity.

An indication that fluorouracil, bromouracil and uracil cross the intestinal epithelium by the same transport system was obtained from experiments in which the foreign pyrimidines depressed the transfer of uracil. For example, at a concentration of 5 m.mol./litre, fluorouracil and bromouracil inhibited completely the active transport of 0·02 millimolar uracil.

The nature of the substituent at the 5-position of the uracil molecule does not appear to be of great importance in determining the extent to which the molecule is actively transported, since uracil, 5-methyluracil (thymine), 5-fluorouracil and 5-bromouracil are all transported across the intestinal epithelium to a similar extent. On the other hand, since the hydrogen, fluorine and bromine atoms and the methyl group have Van der Waals radii of a similar magnitude (1·2–2·0 Å.)[8], it is possible that a considerably larger substituent would interfere with transport of the molecule. Investigations are now being made to determine the structural characteristics of pyrimidines which are required for active transport.

The results of this work suggest that anti-metabolites may not only compete with normal substrates for metabolic processes within the cell, but may also compete with these substrates for transport into the cell.

Changes of Quantity of Flavin in the Brain after Peripheral Administration of Flavins

IT has been reported from our laboratory[1] that flavins produce a change in the electroencephalogram, and that the effect produced by chlorpromazine is partly reversed by flavin adenine dinucleotide. These results suggest that the flavins act on the brain *in situ*. In an attempt to discover the mechanism of action of flavins, their penetration of the blood–brain barrier was examined by determining the amount of flavin in the rat brain after peripheral injection of flavins.

Flavin adenine dinucleotide was prepared by the method of Yagi *et al.*[2]. Flavin mononucleotide and riboflavin were purified chromatographically from commercial samples. Albino rats weighing about 100 gm. were used for the experiment. Fifty animals, 10 days after feeding under the same conditions, were divided into five groups, each group consisting of 10 animals. The animals of the first group were used as control, and injected with water intra-abdominally. Each animal of three groups was injected intra-abdominally with 20 mgm./kgm. (calculated as riboflavin) of flavin adenine dinucleotide, flavin mononucleotide, or riboflavin aqueous solution respectively. The animals of the fifth group were injected with 50 mgm./kgm. of an aqueous solution of riboflavin. One hour after the injection, a blood sample was collected from the carotid artery, and then the animal was killed by decapitation. The quantity of flavin in the brain was measured by the lumiflavin fluorescence method described by Yagi[3], and that in the blood sample was measured by the micro-method for riboflavin in blood described by Yagi *et al.*[4].

Table 1. QUANTITY OF FLAVIN (CALCULATED AS RIBOFLAVIN) IN RAT BRAIN AFTER THE INJECTION OF FLAVINS (μgm./gm. OF WET TISSUE)

	Means of population (n = 10), (α = 0·01)
Controls	3·32 ± 0·35
After the injection of:	
Flavin adenine dinucleotide (20 mgm./kgm.)	3·75 ± 0·69
Flavin mononucleotide (20 mgm./kgm.)	3·73 ± 0·85
Riboflavin (20 mgm./kgm.)	5·18 ± 0·74
Riboflavin (50 mgm./kgm.)	7·37 ± 0·87

The quantities of flavin in the brain after the injection of flavins are shown in Table 1. The variances in the normal cases were rather small, and the values were in good agreement with the earlier results[5]. After the injection of flavin adenine dinucleotide, the increase of flavin in the brain was significant by the t-test with $\alpha = 0{\cdot}1$. In the case of flavin mononucleotide, the increase was significant with $\alpha = 0{\cdot}2$. However, after the administration of 20 mgm./kgm. of riboflavin, flavin in the brain increased, the difference being significant even with $\alpha = 0{\cdot}01$. After the injection of 50 mgm./kgm. of riboflavin, further increase of flavin was observed.

The increases of flavins in blood at 1 hr. after the administration to each animal of 20 mgm./kgm. of flavin were almost equal for the three types of flavins, being less than 1 μgm./ml. of blood. Since the brain contains 0·024 ml. of blood per gm. on the average[6], the increase of flavins due to the blood content of the tissue was about 0·02 μgm./gm. The corrected amounts found by subtracting the values due to the blood from that of the tissue gave a similar result.

It seems, therefore, that the increase of flavin in the brain was due to the penetration of injected flavins from the blood into the brain tissue. It is considered that the flavins penetrate the blood–brain barrier, and that riboflavin can cross this barrier more easily than flavin mononucleotide or flavin adenine dinucleotide.

Reversible Block of Axonal Conduction by Curare after Treatment with Cobra Venom and a Detergent

THE recent experiments of Abbott, Hill and Howarth[1] have revealed that the remarkably high initial heat produced in nerve fibres coincides roughly with electrical activity. This finding re-emphasizes the necessity of explaining electrical activity on a chemical basis. Nachmansohn's theory[2] attributes the change of conductance which initiates the ion movements to the reaction of acetylcholine with a receptor protein. One of the main objections to this theory is the lack of effect of acetylcholine and curare on axons in contrast to their powerful action at junctions. This failure was attributed to the existence of structural barriers for lipid-insoluble quaternary ammonium compounds. Evidence supporting this contention was obtained in experiments on squid giant axons: acetylcholine, labelled with nitrogen-15, and prostigmine failed to penetrate into the axoplasm whereas lipid-soluble tertiary compounds did so readily[3,4]. However, at the nodes of Ranvier, where these barriers are relatively small, curare can rapidly and reversibly block conduction, as shown in recent work by Dettbarn[5]. Walsh and Deal[6] succeeded in partially breaking down these barriers in frog sciatic nerve by treatment with the cationic detergent cetyltrimethylammonium bromide, after which curare and other quaternary ammonium compounds, ordinarily inert on the intact axon, caused reversible block of conduction.

In the present work the squid giant axon was pretreated with a variety of enzymes and detergents in an attempt to permit the action of curare and other compounds. Of the many pre-treatments used, the combination of *Naja naja* cobra venom (10 μgm./ml.) and cetyltrimethylammonium chloride (20 μgm./ml.) applied for 30 min. was most effective in permitting the action of curare applied afterwards on electrical activity. In many experiments, complete and reversible block of conduction was obtained (Fig. 1), sometimes at a curare concentration as low as 5×10^{-4} *M*; $1 \cdot 4 \times 10^{-2}$ *M* curare (10 mgm./ml.) on the intact nerve produced little if any effect.

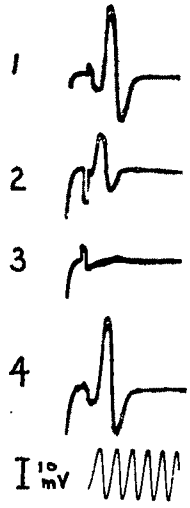

Fig. 1. Effect of curare on squid axon following pre-treatment with 10 μgm./ml. cobra venom plus 20 μgm./ml. cetyltrimethylammonium chloride. (1) Control after 30 min. pre-treatment with cobra venum plus cetyltrimethylammonium chloride. Pretreatment had no effect on spike height. (2) and (3), 5 and 10 min. after application of $1 \cdot 4 \times 10^{-3}$ *M* curare. Conduction was completely blocked, as shown in 3, despite greatly increased stimulus strength. (4) 10 min. after return to sea water. Time signal: 850 c./sec.

The action of a series of tertiary compounds including local anæsthetics (procaine and dibucaine) on the untreated axon was also studied. In each case, these compounds affected conduction at concentrations similar to those required to block synaptic junctions of a single isolated electroplax preparation[7]. Local anæsthetics such as tetracaine and dibucaine, known to block all axonal activity, have recently been shown to react in a highly specific way with the acetylcholine receptor protein[8]. Curare has a high affinity to this protein[9] and has now been shown to block axonal conduction. These results suggest that the receptor protein is present in the axon and is essential for electrical activity. Failure of lipid-insoluble cationic substances such as curare to act on the intact nerve is evidently due to the protection of such receptors by permeability barriers and not to a mechanism which differs basically from that at the junction. Cobra venom and cetyltrimethylammonium chloride probably break down these barriers to an extent which permits curare to react with the receptors and block conduction. The evidence for the action of curare on axonal conduction, to be published in greater detail elsewhere, together with the other results mentioned above, provide new support for Nachmansohn's theory.

HÆMATOLOGY

Hæmoglobin Variants in Sarawak and North Borneo

ABNORMAL hæmoglobins are frequent in south-east Asia[1]. However, only one report of a search for abnormal hæmoglobin variants in Sarawak has so far appeared: among 101 blood samples from Land Dyaks and 85 from Sea Dyaks, only one (from a Land Dyak) contained an abnormal variant and represented the heterozygous state for hæmoglobin *E* [2].

Recently, 1,355 blood samples from Sarawak were studied by the technique of filter-paper electrophoresis at *p*H 8·6. The distribution of samples was Sea Dyaks 68, Land Dyaks 341, Chinese 742, Malay 166, Indian 13, European 23, Eurasian 1 and Filipino 1. All the samples were taken from persons in the First Division of Sarawak and largely from areas within reach of Kuching, and came from hospital in-patients, ante-natal cases and a few out-patients and candidates for government posts. The age distribution was 3–72 years and the sexes were approximately equally represented. All the samples from Sea Dyaks, Land Dyaks, Indians and the Eurasian and Filipino were found to contain only normal adult hæmoglobin (hæmoglobin *A*). Among the samples from Chinese, Malay and European subjects, respectively, 2, 5 and 1 contained a mixture of hæmoglobins *A* and *E*, while 2 samples from Chinese contained a mixture of hæmoglobins *A* and a 'slow' hæmoglobin with properties very similar to those of hæmoglobin *Q*. It has not proved possible to characterize this slow hæmoglobin in great detail. The sample containing hæmoglobins *A* and *E* from a European 'white' came from an English woman whose lineage it was not possible to trace.

Through the courtesy of Prof. T. A. Lloyd Davies, of the Department of Social Medicine and Public Health, University of Malaya in Singapore, it was possible to study 53 blood samples obtained from Muruts inhabiting the Crown Colony of North Borneo. The Muruts are "small, stocky, mongoloid people, with light brown skin and straight black hair"[3]. They are a group of related pagan tribes which have been relatively isolated because they were practising head-hunters until recently. All but 3 of these samples contained only hæmoglobin *A* ; in the rest the pattern was that of a mixture of hæmoglobins *A* and *E*. The slow component in these three samples was probably not hæmoglobin A_2, since it comprised more than 20 per cent of the total hæmoglobin[4].

The absence of any abnormal variants among the Dyaks examined and the solitary finding of one example of hæmoglobin *E* trait by Colbourne *et al.*[2] indicates the infrequency of abnormal variants in these people. The finding of hæmoglobin *E* in 2 Chinese and in 5 Malays parallels similar findings among these ethnic groups in Singapore and Malaya[5]. The existence of a focus of a hæmoglobin, which is probably *Q*, among the Chinese in Kuching is indicated.

We are grateful to Dr. W. Glyn Evans, director of Medical Services, Sarawak, for permission to carry out this investigation.

Production of *B* Character on Human Erythrocytes by Hæmosensitization with Purified *Escherichia coli O* 86 Substance

The serological specificity of the human blood group substances *A* and *B* is due to characteristic polysaccharide components[1]. Recently, the same has been found to apply to the *Salmonella O* antigen[2]. The serologically active component, a lipopolysaccharide, was isolated from the bacteria and submitted to chemical analysis, which showed that in various strains within the same *O* group or *O* sub-group, the *O* antigen is of an identical qualitative-chemical composition, that is, it contains the same 'Zuckerbausteine'.

A lipopolysaccharide from *E. coli O* 86, obtained by this procedure, was placed at my disposal. An investigation was conducted to ascertain whether this purified preparation, of known qualitative-chemical composition, might possess blood-group activity of *A* and/or *B* specificity. By previous work[3,4] and my earlier work it had been shown that *E. coli O* 86 contained *A*-like and *B*-like substances. The investigation was carried out by hæmosensitizing human *O* cells with the purified lipopolysaccharide by the following procedure :

Table 1. Sensitized *O* Cells and Normal *B* Cells in different Anti-*B* Reagents
(All reactions performed on a glass plate at 20° C. ; readings after 10 min.)

	Human *AB* serum or anti-*A*	Human anti-*B*	Human anti-*B* absorbed with human *B*	Human anti-*B* absorbed with rabbit *B* (β_1)	Human anti-*B* absorbed with sensitized *O*
Normal *O* cells	–	–	–	–	–
Sensitized *O* cells	+	+++	+	+	–
Normal *B* cells	–	+++	–	+	++

	Rabbit immune anti-*B* (β_1)	Chicken immune anti-*B* (β_2)	Chicken immune anti-*B* absorbed with human *B*	Chicken immune anti-*B* absorbed with rabbit *B*	Chicken immune anti-*B* absorbed with sensitized *O*
Normal *O* cells	–	–	–	–	–
Sensitized *O* cells	–	++	–	–	–
Normal *B* cells	+++	+++	–	–	++

	Eluate from human *B* cells incubated with human anti-*B*	Eluate from sensitized *O* cells incubated with human anti-*B*	Eluate from sensitized *O* cells incubated with human anti-*B* and absorbed with human *B*	Eluate from sensitized *O* cells incubated with human anti-*B* and absorbed with rabbit *B*
Normal *O* cells	–	–	–	–
Sensitized *O* cells	–	++	–	–
Normal *B* cells	+++	+++	–	–

10 mgm. of lipopolysaccharide from *E. coli O* 86 was dissolved during heating in 10 ml. re-distilled, sterile 0·9 per cent saline solution (stock solution). For purposes of the hæmosensitization the stock solution was diluted 10 times with sterile 0·9 per cent saline solution. To 20 volumes of this solution was added 1 volume of packed, thoroughly washed *O* cells, and the mixture was incubated in a water-bath at 37° C. for 1 hr. After incubation, the blood cells were again washed and then tested in various blood-group reagents of anti-*A* and anti-*B* specificities. The results are given in Table 1.

The sensitized *O* cells agglutinated in human anti-*B* sera, showing a strength of agglutination apparently dependent on the strength of the anti-*B* present. In undiluted serum the strength of agglutination was equal to or slightly weaker than that with normal *B* cells, but the titre against sensitized *O* cells was lower than against normal *B* cells. The agglutination was weakened or abolished by addition of *B* saliva, but not of *A* saliva or *O* saliva, by absorption with *B* cells, but not with *A* cells or *O* cells. In human anti-*A* sera or *AB* sera, there was generally a weak reaction of the same order of magnitude as the reaction which remained in the neutralized or absorbed anti-*B* sera.

Incubation of the sensitized *O* cells in human anti-*B* sera with elution afterwards of the antibody (by the Landsteiner method) resulted in an eluate reacting with *B* cells and sensitized *O* cells, but not with *A* cells or with normal *O* cells. On the other hand, an eluate made by using the same serum and *B* cells reacted exclusively with *B* cells, not with sensitized *O* cells.

Absorption of human anti-*B* sera with sensitized *O* cells induced an unmistakable reduction of the anti-*B* content. In the same way, the lipopolysaccharide solution was able to abolish the reaction of *B* cells in anti-*B* sera. Conversely, there was no neutralizing effect of the solution on the agglutination of *A* cells in anti-*A* sera.

Sensitized *O* cells were tested in rabbit immune anti-*B* (specificity β_1) and chicken immune anti-*B* (specificity β_2)[5]. The cells gave a negative reaction with rabbit immune anti-*B*, but a positive reaction with chicken immune anti-*B*. Absorption of chicken immune anti-*B* with rabbit cells abolished the reaction with sensitized *O* cells.

As mentioned previously, the sensitized *O* cells reacted with practically all the human anti-*A* sera and *AB* sera tested. There was no distinct difference between anti-*A* sera and *AB* sera. The sensitized blood cells gave negative reaction with anti-*T*. Thus, the purified lipopolysaccharide from *E. coli O* 86 must contain a reactive group against which most human beings possess an antibody.

Analysis of the preliminary results, as shown in the table, supports the presumption that the purified lipopolysaccharide from *E. coli O* 86 contains a reactive group similar to blood-group factor *B* in man and the *B*-like factor in rabbit cells. However, it does not seem to be identical with human *B* or rabbit *B*.

The so-called A^b cells[6-9] also had an atypical *B* character which was weaker than the normal *B* factor on human *B* cells. It might be imagined, therefore, that they bear a certain relation to the artificial *B* cells produced in this work. It has, in fact, been suggested that the A^b character might be considered to be acquired[7-9]. There are points of resemblance between the *B* character on the A^b cells and the *B* character on the sensitized blood cells, but there are differences as well. While the A^b character has been found only in *A* persons, there was no demonstrable difference, qualitative or quantitative, between sensitized *A* cells and sensitized *O* cells, when tested in a series of anti-*B* sera and *AB* sera. Further work is needed, however, to elucidate the relation between the *B* characters on the different types of blood cells.

I am indebted to Dr. O. Westphal, A. Wander Forschungsinstitut, Freiburg-Zähringen, for the generous supply of purified lipopolysaccharide from *E. coli O* 86, and I wish to thank Dr. F. Kauffmann and Dr. F. Ørskov, of the International Salmonella and Escherichia Centre, Statens Seruminstitut, Copenhagen, for valuable assistance.

PATHOLOGY

Effect of Essential Oils on Atherosclerosis of Cholesterol-fed Rabbits

On glancing through the international literature we do not find any information on the therapeutical application of well-known pharmacological products, like the essential oils, in the treatment of atherosclerosis, and no experiments have been carried out on this subject. The essential oils are ingredients of plants and are readily soluble in most of the organic solvents. They contain mainly various terpenes like menthol, camphor, pinene, borneol, cineol and other compounds. The chemical structure of the majority of terpenes has been determined.

The terpenes preferably penetrate into cells of high lipoid content. Menthol presents an affinity to nerve receptors, camphor—according to several authors—to the vasomotor centre. Alpha-pinene, like the bicyclic terpenes, exerts a chemotactic effect on leucocytes[1-4].

The physico-chemical properties of essential oils and their remarkable affinity to cells with high lipoid content induced us to test their efficacy in atherosclerosis. In our investigations we used a terpene mixture consisting of borneol, camphenes, cineol, menthol, menthone and pinene. (We owe thanks to Messrs. Rowa-Wagner G.m.b.H., Bensberg/Cologne, Western Germany, for providing us with the necessary quantities of this product.)

Our investigations were carried out on male rabbits weighing 3,000 gm. We induced atherosclerosis by cholesterol feeding as described by Anichkov and Chalatov[5]. 1 gm. of cholesterol added to bran-balls was given daily to 20 rabbits of the first test group and to 12 rabbits of the second. Basically, we applied 1 ml. of the terpene mixture by subcutaneous injection every other day to ten rabbits of the first test group. Due to the occurrence of sterile abscesses in some rabbits 6 wk. later, the administration of the terpene mixture was continued orally for another 6 wk. Six animals of the second test group received the remedy orally throughout the whole test period of 3 months. Rabbit food consisted of lucerne and beet besides the bran-balls.

In both test groups four animals died. Thus 12 animals of each group remained for evaluation. Blood cholesterol-level was determined at the beginning, and at the end of our investigations showed an increase up to 1,048 ± 82 mgm. per cent, in comparison with an initial average level of 130 ± 24 mgm. per cent. We encountered a similar rise of cholesterol esters, the rate of which, however, was somewhat less than that of total cholesterol. Paper electrophoresis revealed a very significant increase of the beta-lipoprotein fraction in both groups. In autopsy we established hepatomegaly; a considerable storage of cholesterol in the liver was found in the animals of both groups by histochemical methods. Examination of the aortal intima revealed decisive differences between the terpene-treated animals and the controls. In the controls of the first series, we observed widespread atherosclerotic plaques in the aortal intima amounting to more than 45 per cent of total aortal surface as measured by planimeter. The number as well as the extension of these plaques in the aortæ of the treated animals of the same group were much less than in the controls; they affected merely 13 per cent of the total aortal intima (Fig. 1). In the other test group, however, essentially no atherosclerotic

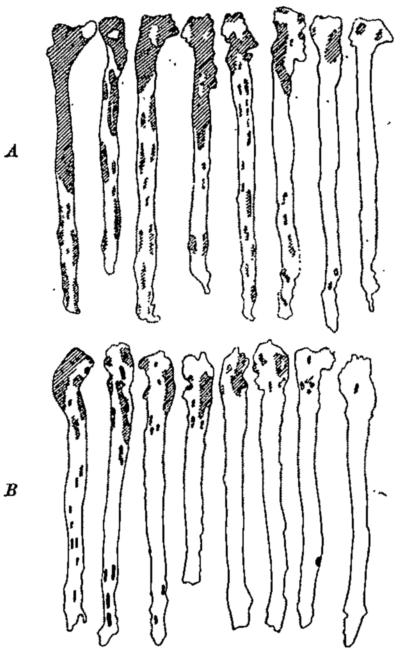

Fig. 1. *A*, Aortæ of terpene-treated animals; *B*, aortæ of controls

plaques appeared in the aortæ of the treated animals compared with those of the untreated ones (Fig. 2).

These findings are rather noteworthy in view of the fact that terpene treatment did not impair the absorption or storage of cholesterol, and that it did not inhibit the increase of serum cholesterol-level. Nevertheless, the terpene compound prevented remarkably the development of atherosclerotic plaques.

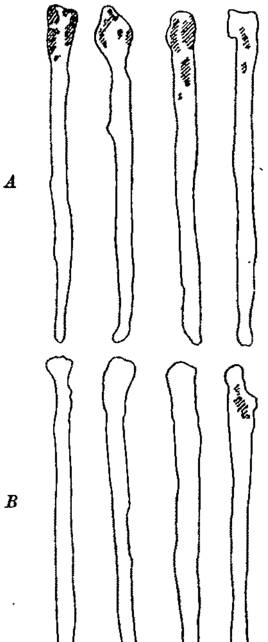

Fig. 2. *A*, Aortæ of terpene-treated animals; *B*, aortæ of controls

Impaired lipoid metabolism is nowadays generally considered to be one of the most important pathogenic factors causing atherosclerosis[6–9]. All the therapeutical measures have in common the tendency to remove these disorders. In dietetics, the important role of unsaturated fatty acids has been pointed out recently[10]. All the procedures aim at normalizing the blood lipoid-level. It is well known, however, that a high level of serum cholesterol is not always associated with atherosclerosis, as demonstrated by cortisone-induced hypercholesterolæmia, by nephrosis, and by certain forms of cirrhosis. Gerő and co-workers[11] reported a significant decrease of atherosclerosis originating from lipoprotein immunization in spite of high cholesterol-levels. We also suggest that the formation of atherosclerotic plaques is prevented by a terpene treatment, notwithstanding the high levels of serum cholesterol. We suppose that this effect of the terpenes partly results either from some competitive inhibition, or perhaps they act by blocking mediatory factors promoting the penetration of lipoids into the arterial wall.

Influence of Uræmia on the Survival of Skin Homografts

Couch *et al.*[1] have shown that homografts of skin may survive for prolonged periods in a uræmic patient. They considered that this extended survival might be due to an impairment of immune responses in the patient. However, there is evidence to show that in patients with both acute and chronic uræmia the production of certain classical antibodies is within normal limits[1–4]. Stoloff *et al.*[3] have suggested that while the synthesis of classical antibodies may be impaired by uræmia, the production of intracellular antibodies may be inhibited. However, in chronically uræmic patients the Mantoux test may be positive, implying that the formation of intracellular antibodies may also be maintained[2].

Since the principal response to orthotopic skin homografts occurs in the draining lymph nodes[5,6], the effect of acute uræmia on the regional lymph node reactivity to skin homografts has been investigated in 33 uræmic and 23 control rabbits. The animals used were adult females of albino and Flemish Giant strains. Animals from each strain were paired,

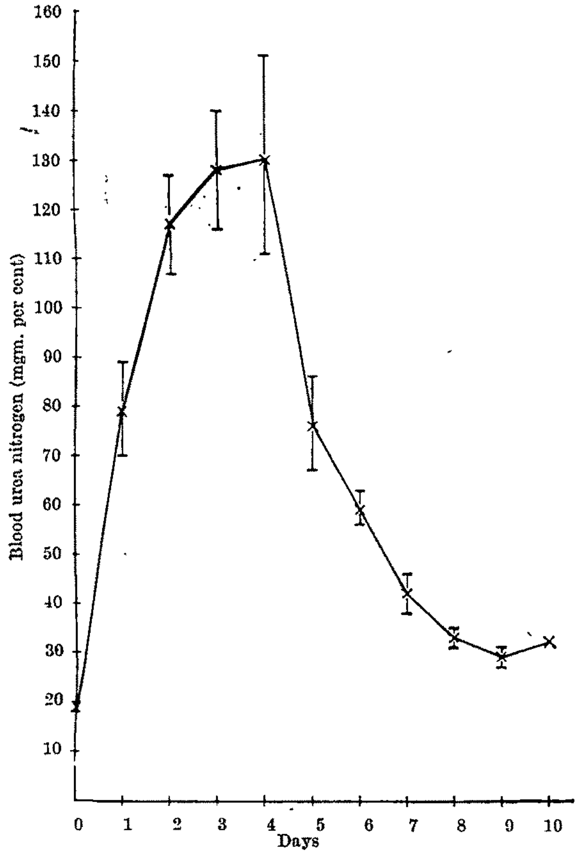

Fig. 1. Graph showing daily level of the blood urea nitrogen after occlusion of the right renal pedicle for 2 hr. Nephrectomy simultaneously performed on the opposite side

and under sodium pentobarbitone anæsthesia circular skin grafts 2 cm. in diameter were exchanged between the right ears. Acute uræmia was produced by means of unilateral nephrectomy, after which the pedicle of the other kidney was clamped for 2 hr.

Each day the grafts were inspected, the animals weighed and blood samples were taken from the left ears of the uræmic animals for blood urea nitrogen estimations. The animals were killed at intervals of time up to 14 days after operation. The parotid lymph nodes on the side containing the graft and on the contralateral side were removed, weighed and fixed in Carnoy's fluid.

The mean initial rejection-time of skin homografts exchanged between twelve healthy rabbits was 5·1 ± 0·9 days, whereas in eight uræmic animals, the mean initial rejection time was 10·8 ± 1·5 days. These observations have not been subjected to a *t*-test because the data are censored, implying that the sample of rejection times is not representative of the values which would have been obtained if all the rabbits had been allowed to live until the homografts were rejected. The criteria used for assessing the earliest signs of graft rejection were cyanosis, papillary congestion and intra-epidermal œdema appearing in skin which had shown evidence of survival. The blood urea nitrogen-levels in the uræmic group (Fig. 1) rose to a maximum between the fourth and the sixth day after grafting, and then fell rapidly towards normal levels. Two rabbits in which a secondary ante-mortem rise in blood urea nitrogen occurred have been excluded in the preparation of this graph. The mean absolute weight of the first regional lymph nodes draining the skin homografts at each time-interval after grafting in the control animals increased rapidly to a maximum by the sixth day after operation (Fig. 2), confirming the findings of Scothorne and McGregor[6]; the secondary rise in weight of lymph node after the tenth post-operative day was probably due to separation of the graft and infection of the graft bed. In the uræmic animals (Fig. 2) increase in the mean absolute weight of the first regional lymph nodes on the side receiving the graft was delayed until after the sixth day, by which time the azotæmia was returning towards normal levels (Fig. 1). A mean maximal weight was not reached until the tenth day, at about the time of graft rejection, which occurred at 10·8 ± 1·5 days. A secondary rise in weight of lymph node similar to that previously observed in the control group occurred after the twelfth post-operative day. Statistical analysis of the mean absolute lymph node weights between the uræmic and the control groups at each time interval has revealed a highly significant difference at the sixth ($P < 0.001$) and eighth ($P < 0.001$) days after operation.

Histological examination of first regional nodes draining tissue homografts has revealed the appearance of great accumulations of 'large lymphoid cells'[6-10] which reach a maximum between the fourth and sixth days after grafting[10]. The histological aspects of the present work will be reported in a further communication.

It is possible that acute uræmia exerts its effect of prolongation on skin homograft survival by a direct depression of the immunological reactivity of the lymph nodes draining the graft. However, the non-specific stress of the operation together with the acute uræmia may result in adreno-cortical stimula-

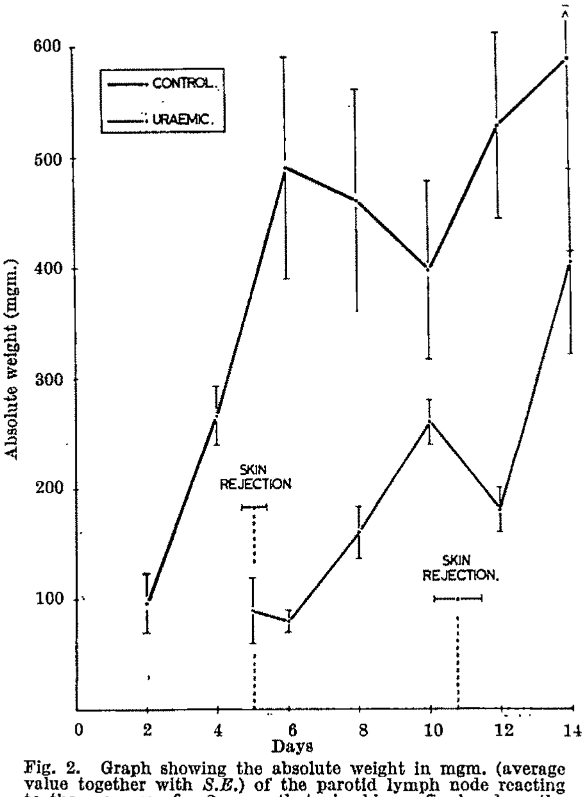

Fig. 2. Graph showing the absolute weight in mgm. (average value together with *S.E.*) of the parotid lymph node reacting to the presence of a 2-cm. orthotopic skin graft placed on the ventral aspect of the right ear. Control group above; uræmic animals below

tion. There is evidence to show that systemic or topical administration of cortisone acetate will prolong survival of skin graft in rabbits[11–13]. The possibility that the observed prolongation of skin homograft rejection time in rabbits with acute uræmia is due to adreno-cortical hyperfunction is being investigated at the present time. Further, the uræmic state of the recipient may inhibit the antigenicity of the homografted skin, a view which has been suggested as one of the ways in which cortisone may extend skin homograft survival[14]. An attempt was made to put the possibility of reduced antigenicity by uræmia to the experimental test, by grafting skin from severely uræmic rabbits on to six healthy rabbits. The mean initial rejection time of the skin homografts in this group of animals was 5·4 ± 0·5 days, a rejection time which is little different from the control group. Finally, Stoloff *et al.*[3] suggested that uræmia may act in prolonging homograft survival by diminishing the receptivity of the graft to the immune responses of the host. In the light of the impaired reactivity of regional lymph nodes draining skin homografts in the presence of acute uræmia, diminished receptivity of the grafts would seem unlikely to play anything more than a minor part in the extension of skin graft survival time produced by acute uræmia. A further and more detailed account of our findings will be given later.

A New, Highly Effective but Non-Toxic Antibacterial Substance

WE have discovered an entirely novel drug which is a polycondensed urea-formaldehyde having quite unexpected properties.

This polycondensate was found during a routine search for new classes of compounds with bacteriostatic properties. It is produced by a simple process of 'curing' a water-soluble pre-condensate of formaldehyde and urea units by high-temperature evaporation in a spray-tower at ordinary pressure and an alkaline *p*H. The resultant material is known as 'Anaflex', which is an amorphous white powder soluble to the extent of 0·28–0·31 per cent in water. It shows broad-spectrum bacteriostatic properties which are discussed here.

This product is a distinct entity, and differs from the well-known products resulting from 'curing' the water-soluble pre-condensates of urea formaldehyde with acid reagents at either high or low temperature as these are always devoid of any bacteriostatic activity.

Because of the low solubility of the new material it has proved difficult adequately to assess its physical constants. It is not crystalline and when heated it decomposes without melting.

Carbon–hydrogen–nitrogen analysis gives constant values, namely: C, 35·96; H, 5·88; N, 27·72; C, 35·68 ; H, 6·05 ; N, 27·76 per cent. This indicates $C_6H_{12}O_4N_4$ as a unit of the polycondensate molecule. $C_6H_{12}O_4N_4$ calculated gives: C, 35·29 ; H, 5·92 ; N, 27·44 per cent.

Both the oxygen and hydrogen content of the molecule is higher than would be expected from simple cross-linking of urea and methylene groups. We, therefore, feel that many free oxymethylene-substituents occur within the molecule and are responsible for the strong bacteriostatic activity.

This new material has been investigated to assess its effect as a bacteriocide against the following organisms :

Staphylococcus albus
Staph. albus (penicillin insensitive)
Staph. aureus, coagulase positive
Staph. aureus, coagulase positive, type 43
Staph. aureus, coagulase positive and penicillin and tetracycline insensitive
Strept. viridans (α-hæmolytic)
Strept. pyogenes (β-hæmolytic)
Micrococcus tetragenus
Strept. lactis (from fermented milk)
Pneumococcus
B. coli strain 1
B. coli strain 2
B. coli strain 3
Ps. pyocyanea, type 1
Ps. pyocyanea, type 2
Proteus morgani
Salmonella paratyphosum A
S. paratyphosum B
S. paratyphosum C
S. mixed organisms
S., local type
Sh. dys. sonne
Sh. dys. schmidt
Lacto bacillus
N. catarrhalis sicca
N. catarrhalis, smooth type
Alkaligenes alkaligenes
Candida albicans, type 1
Candida albicans, type 2
Unidentified yeast
Trichophyton, type 1
Trichophyton, type 2
C. diphtheriae
C. hoffmani
C. xerosis
Aspergillus niger
A. rubrum
B. subtilis

Because of the low solubility in water the tests were carried out by Fleming's disk and ditch methods and the resulting zones of inhibition have been assessed.

In addition, in suitable liquid media which include 1 per cent glucose nutrient broth and modified brewer's broth, a suspension of 1 per cent of the new material w/v has shown similar inhibiting effects. Detailed tests have been made to eliminate bacteriostatic results by serial sub-dilutions in the appropriate media.

On serial sub-cultures of known micro-organisms from the periphery of the zones of inhibition repeated up to 100 times, no resistant strain of any of the test organisms has emerged. After these striking laboratory results the investigations have been extended to more than 200 human patients and these comprise at least :

40 cases furunculosis
20 ulcus cruris
22 infected pressure sores
14 infected acne
44 gynæcological discharges
14 napkin rash
20 infected industrial wounds
7 fungal paronychia
9 athlete's foot
15 proctological cases
20 cutaneous hypersensitivity
11 axillary infections
2 seborrhœa capitis

Method of use. Clinically it only appears necessary to apply the medicament twice daily—preferably directly to the affected part—with a 'ring' of dressing to the circumambient areas to minimize secondary spread. In most cases occlusive dressings are contra-indicated.

The antibacterial spectrum is very wide, both *in vitro* and *in vivo*. It is not claimed that all the patients treated were cured ; but it should suffice to indicate that more than 80 per cent of the furunculosis cases were cured in less than 4 days. In cases where treatment was instituted within 48 hr. of the appearance of the initial lesions, these failed to develop into classical boils and the lesions disappeared in a further 48 hr.

A small comparative trial of nasal barrier creams was instituted. A well-known commercial cream containing chlorhexidine was used as the control. 'Anaflex' removed the infection from nasal carriers of penicillin-resistant *Staphylococcus* within 4–5 days; chlorhexidine produced a similar effect in 2–3 days but relapses occurred within 3 days. With 'Anaflex' relapses to the carrier state took at least 7 days.

It has proved in our hands extremely difficult to account for the mode of action of 'Anaflex'. It might be argued that it is due to a slow release of formaldehyde and indeed on treating this material with 4*N* sulphuric acid, 53 ± 1 per cent, formaldehyde is quantitatively liberated. But it has been found to be effective in urinary dermatitis (which has an ammoniacal basis). It is not possible to detect formaldehyde in the solution derived from 'Anaflex'. The distillate from such a solution is completely devoid of bacteriostatic effect and also of formaldehyde.

We have reason for believing that the bacteriocidal effects of the new material are enhanced by the presence of electrolytes and/or body proteins.

HISTOCHEMISTRY

Cholinesterase in the Chicken Nervous System

WHILE making a topographical survey of the distribution of cholinesterases in the spinal cord and brain stem of the chicken in relation to the question of the selective neurotoxicity of certain organophosphorus compounds, we were led to make a comparison in four laboratory mammals (to be published). Koelle[1] had shown histochemically in the rat that considerable variation exists in the cholinesterase content of neurones from one centre to another. Hebb[2] also recognized in mammals neurones where the cholinesterase was for the most part intracellular (cholinergic) and neurones where it was largely distributed on the neuronal membrane (cholinoceptive). In contrast to this variability in mammals, the distribution of cholinesterase in chicken neurones is strikingly uniform.

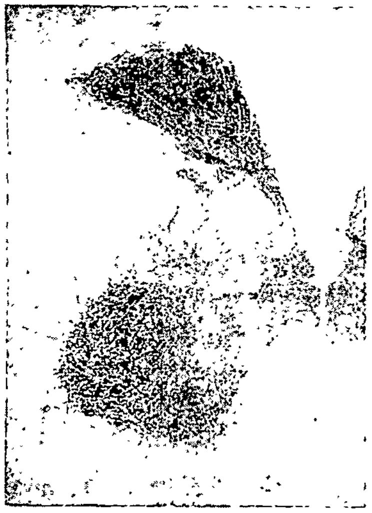

Fig. 1. Cervical spinal cord of guinea pig. Acetylthiocholine; Gömöri technique; *p*H 6·5; 2-hr. incubation

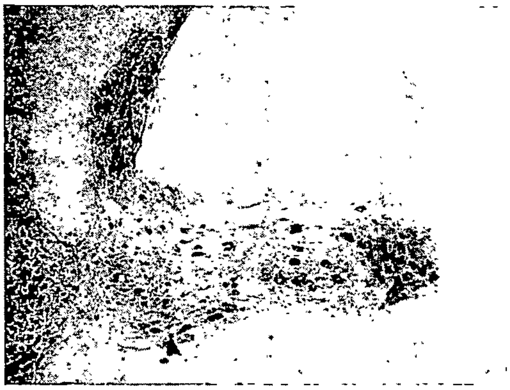

Fig. 2. Cervical spinal cord of chicken. Acetylthiocholine; Gömöri technique; *p*H 6·5; 2-hr. incubation

All nerve cells of sensory ganglia, spinal cord and brain stem contain an abundance of this enzyme, and variation in content seemed to be related to neurone size. It is particularly interesting that the dorsal root ganglia cells are so active, for in mammals these cells are very poor in this enzyme while many contain none at all[3]. Hebb[2] likewise found that the second-order sensory cells in the cat were rich in enzyme, but not the primary cells. In the mammalian spinal cord (Fig. 1) cholinesterase is seen histochemically to be concentrated in the lateral and ventral regions and appears to be related both to neuronal surfaces and perikarya, the relative abundance at each area varying with the species. In the chicken relatively little is seen at cell surfaces, while all neurones show cholinesterase activity in their perikarya (Fig. 2). A similar constancy of distribution is found in the brain stem neurones.

On the other hand, certain richly synaptic zones such as the posterior horns of the spinal cord (Figs. 1 and 2), the descending root of the Vth nerve and certain cochleo-vestibular centres in the chicken contain an abundance of cholinesterase just as they do in the mammals examined. But the molecular layer of the cerebellum, which is also a richly synaptic area and also contains much cholinesterase in the chicken, is negative in the rat, rabbit and cat. In the guinea pig, however, it is almost as active as in the chicken.

If the presence of cholinesterase, shown in this work by its substrate and inhibitor characteristics probably to be true cholinesterase, is an index of the presence of a cholinergic transmission mechanism, then it would appear that the chemical transmission system of the chicken is probably of a simpler overall type than in higher species. On the basis of evidence, largely drawn from work on mammals, Hebb[4] has concluded that cholinergic transmission is probably not universal and is limited to only a proportion of cells, and that the rest must use some alternative chemical system for this purpose. It is to be questioned whether these conclusions are in fact true for submammalian species or even whether absolute uniformity is to be expected among mammals as to which chemical system is employed in each region. Apart from the bearing that these findings have on the evolution of possible transmission systems, they emphasize the necessity for not drawing too close a comparison between the chicken and higher species when this animal is used for the purposes of experimental neurology.

BIOLOGY

Sucker Display of Octopus

As a cephalopod, *Octopus vulgaris* is capable of the fastest and some of the most varied colour changes in the animal kingdom; yet there is a remarkable lack of evidence for these being used in courtship or mating displays of the kind associated with brightly coloured vertebrate animals. Courtship colour display by a less studied octopus (probably *O. horridus*) has been observed by Young[1], and the dramatic 'zebra' pattern of the decapod, *Sepia officinalis*, which is used both in courtship and as a threat between males, is well known.

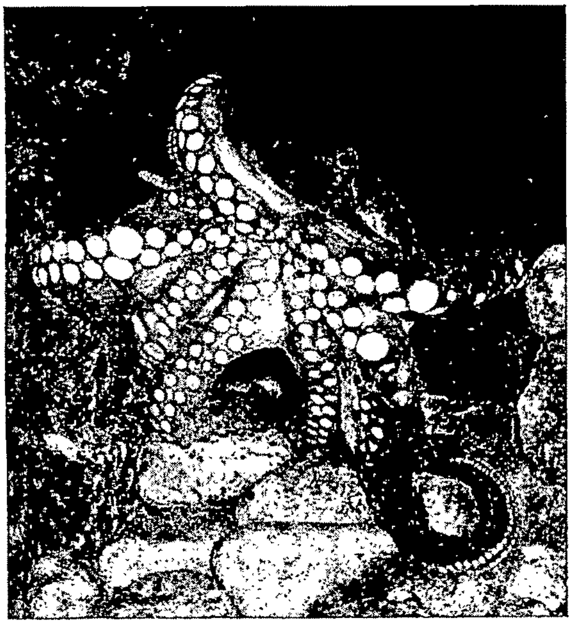

Fig. 1. Photograph of a male (about 4 kgm.) displaying its suckers in response to a female approaching on its left side. The uppermost arm on the right of the photograph is arm 2 of the animal's left side; arm 1 left being held over towards the right side; arm 1 right is regenerating. Note the characteristic large suckers of the male on arms 2 and 3

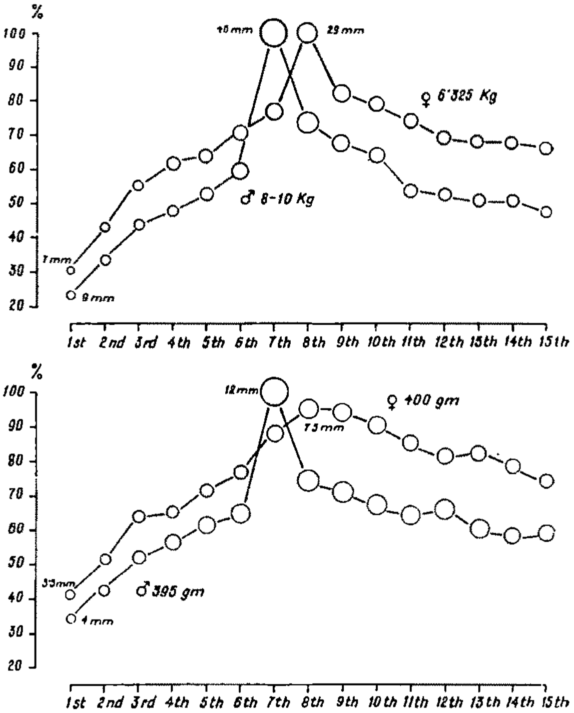

Fig. 2. Relative sizes of suckers at different levels on two males and two females of comparable weights. At each level outwards from the mouth the size of the sucker is given as a percentage of the diameter of the largest in the row. Plots are the average of measurements for single rows of suckers on arms 2 and 3 of either side. The diameters of the largest and of the most proximal suckers are indicated in millimetres. Measurements are from dead specimens

Reviewing the colour patterns of *O. vulgaris*, it soon becomes obvious that the well-known ones, for example, the dymantic 'startling' pattern described by Young, the deep reddening during an attack on a prey, and the various mottled patterns that clearly serve as protective coloration in different backgrounds, have an interspecific value rather than being intraspecific. The lack of information about colour patterns used intraspecifically may be due to the fact that the observer invariably takes part in an interspecific relationship with the animal and only rarely finds himself in a position to watch an intraspecific one. But a recent observation suggests that chromatophore colour patterns used in communication between one octopus and another may be of less importance than another signalling device, namely, the suckers.

During an encounter between one male *O. vulgaris* and a female in the Naples Aquarium, the male was seen to display its upturned arms while holding a position among the rocks from which it had just ousted the female. A photograph, taken at the time (Fig. 1), shows that certain suckers on the second and third arms of either side are larger than the others. It has not apparently been realized before, unless by Aristotle[2], that these are a regular external sexual character of the male *O. vulgaris* in addition to the hectocotylized tip of the third right arm. The presence of extra-large suckers at the level of the seventh or eighth pair, counting outwards from the mouth on arms 2 and 3 on either side, has now been found to be a reliable guide for the determination of mature males from females. At this level in both sexes the suckers, which increase in size outwards from the mouth, begin to decrease in size towards the arm tips, but in the male the largest sucker is proportionately larger than that in the female (Fig. 2).

A second observation made when a small but mature male was introduced to a female (four times his size) confirmed the impression that these large suckers are used as display between male and female. The body of the male was raised above the floor of the tank in such a way that the suckers near the mouth were showing with their undersides towards the female, and he approached with the third right arm outstretched in her direction. The proximal suckers were closed, by being folded on themselves, but the extra-large ones were, by contrast, expanded. Fig. 1 was taken at a moment when a female, attracted by a crab held close to the male, was approaching from the right of the photograph. It will be noticed that the closed suckers (here considered to be part of the complete display providing maximum contrast of expanded white on a dark ground) occurs on the side of the approaching female only. This is another example of unilateral response often observed in *Octopus* (also *Sepia*) when monocular vision is being used.

Another form of the sucker display used during copulation, and mentioned by Racovitza[3], has also been seen in the Naples Aquarium. While the male, sitting at right angles to the female, has his third right arm stretched into her mantle opening, the second right arm is curved back over the head so that the female is presented with a vertical double row of open suckers, the extra-large male suckers being the most conspicuous and directed with their expanded surfaces towards her.

Possible use of the sucker display by the male is as a recognition signal: male-to-female, especially important when the male is smaller than the female and might otherwise be attacked. Males mature at weights as little as 200 gm., females not until 2·5 kgm. or more[4], and it may be a normal requirement for small males to copulate with much larger females. To do so is to reverse the tendency of a small animal to withdraw from a larger one, as from a source of potential danger. A common feature of the withdrawal response of *O. vulgaris* is a turning up of the edges of the withdrawn arms so that the suckers, the surfaces of which are usually hidden by being in contact with the substratum, become visible especially on the stimulated side where the withdrawal proceeds further. This is often seen in training situations when animals are presented with a stimulus associated with punishment. In extreme withdrawal the arms are brought back over the head and mantle so that the suckers of all arms are visible. A film taken underwater of an octopus disturbed by a fish, shows very clearly how the moment in which the edges of the first arms are upturned, exposing the suckers, coincides with the closest approach of the fish, which then immediately halts and backs away. Such an interspecific display—as the movement clearly has become—develops directly from the protective withdrawal of the arms over the head. The sudden appearance of white circles, as upturning begins, startles the intruder.

The appearance to an octopus of white shapes on a dark background have for the past years been the subject of many experiments at Naples, and a white object such as a handkerchief or piece of plain cloth or white stone lowered into the water and dangled in front of an octopus has long been used by Neapolitan fishermen to lure an octopus out of its hole when no bait is handy or when other methods have failed. Boycott and Young[5] have considered the relative value as stimuli of rectangular and circular figures of the same area and Young[6] concludes that circles are attacked more readily than rectangles, while N. S. Sutherland (unpublished) has evidence that, of two different sized white circles presented together, the larger (within a diameter range of 2·7–5·6 cm.) is preferred even when attacks on both are rewarded.

The infundibular surfaces of the suckers are circular; they are white because the skin here lacks chromatophores: the outer keratinous layer of the skin of these surfaces is repeatedly renewed to maintain the efficiency of the suckers as adhesive organs. Therefore, given the existence of white circles as part of the anatomy of the animal and their visible appearance in only certain behavioural situations, it is not difficult to imagine that they should also have evolved a significance in communication, though we know almost nothing of how specific or capable of refinement this communication is.

Movement of Coarse Fish in Rivers

IT is generally accepted[1] that coarse fish move to shallow water in the spring in order to spawn, and retire to deep water in the winter, but how extensive these movements are is not known. Work on American species has given rise to the concept of a 'home range'[2] which may be restricted to as little as a few 100 ft., and it has also been suggested that some species, including carp, are best regarded as having populations composed of mobile and sedentary fractions the relative proportions of which determine the degree of mobility shown by the species[3].

Investigations of coarse fish movements were made in the River Thames, near Reading, in 1959 and in the River Mole, in Surrey, between July and September 1960. The fish population in the Mole was repeatedly sampled by electric fishing at 14 stations, each about 200 ft. long, over a mile of the River. The catch, mostly roach and gudgeon, was marked either by fin clipping or by the attachment of a light metal tag, and released at the centre of the station in which it was caught. Altogether, 3,252 fish were marked over a period of five weeks and a total of 374 was recaptured during this period and a subsequent sampling period of two weeks.

The results showed no correlation between the time that fish had been at liberty and the distance travelled. Instead the frequency distribution of recaptures showed marked grouping about the point of release. In order to ascribe proper weighting to the distribution, the sampling effort exerted and the numbers of marked fish present have to be taken into account. The efficiency with which a station was sampled has been calculated as the fraction obtained by dividing the number of recaptured fish which were marked in the first week of the investigation by the

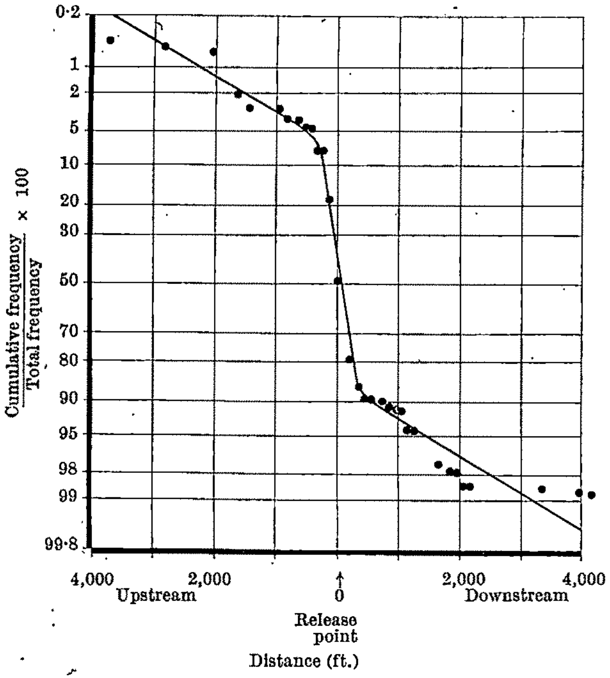

Fig. 1. Distribution of roach recaptures about the release point

total number of fish marked in the station during the first week. An analysis of variance showed that all samples could be regarded as having been taken with similar efforts. Therefore the weighting due to an individual recapture is given by :

$$\frac{1}{M_t.S_t}$$

where M_t is the number of marked fish present in the station of marking up to time t, and S_t is the number of samples taken up to and including time t at the station of recapture.

The corrected distribution is illustrated for roach in Fig. 1, where the cumulative frequencies are expressed as percentages of the total frequency and plotted on a probit scale against the distance from the station of marking. Using this method, a normal distribution gives a straight line with the slope of the line being a measure of the dispersal. However, in this case, a sigmoid curve is obtained which could be interpreted as the result of a combination of two normal distributions of differing dispersions. This seems to suggest that the roach population in the River Mole is made up of two components : a larger group comprising about 80 per cent of the individuals which remains within a range of 650 ft., and a smaller group of 20 per cent which moves more freely.

The weighting formula used introduces bias against recaptures showing no movement since M_t should be decreased by the unknown number which have left the station of marking. This makes the estimate of the proportion formed by the less-mobile group too low and its range too high ; but, since relatively few fish were taken outside the station in which they were marked, the differences will not be great.

The division of fish populations into two groups of differing mobility could provide an explanation of the apparently speedy recolonization of waterways by fish which, by the nature of their habitat, would be expected to exhibit station-holding behaviour.

Similar work is planned to investigate the movements of coarse fish throughout the year.

Unilateral Implantation in the Uganda Kob

The Uganda kob, *Adenota kob thomasi* (P. L. Sclater), an antelope almost entirely endemic to Uganda, East Africa, inhabits primarily grassy plains along major rivers and lakes in the Western Rift Valley at elevations of 625–900 m. Its range extends approximately from 1° S. latitude to 4° N. latitude. Annual rainfall averages about 100 cm., and daily temperature varies approximately between 20° and 30° C. Breeding occurs throughout the year on special territorial grounds[1]. Gestation probably lasts about 7½ months, and normally the females are monotocous.

In the Semliki Game Reserve, 30 km. north of Fort Portal, Uganda, at 1° N. latitude, 150 mature female Uganda kob were collected. 12–15 individuals were shot each month during July 1957–June 1958. In addition, 10 females were taken immediately north of Murchison Falls National Park in the vicinity of Lolim Ranger Post. The position of the conceptus and distribution of cotyledons with respect to right and left horns of the bicornuate uterus were noted. Location of the most recent corpus luteum was recorded as to right and left ovary. Additional linear, weight and volume measurements were made of the uterus, extra-embryonic membranes and fluids, fœtus and ovaries. Analyses of these results are being prepared for publication. Samples of extra-embryonic tissues, ovaries, embryos, and fœtuses of less than 100 mm. crown-rump measurement were preserved.

Ovulation occurred at random between right and left ovaries (Table 1). In the tabulation, size of ovary is based on linear measurement, to the nearest millimetre, of the greatest three dimensions of the ovary prior to fixation. In pregnant females the larger size indicates the presence of a corpus luteum of pregnancy ; in non-pregnant females the larger size represents either a degenerating corpus luteum or an enlarged follicle. The present results support the principle of random distribution of ova released between right and left ovaries in monotocous species. Brambell[2] cites evidence for random distribution in the cow, sheep and monkey. Annual alternation between ovaries may occur, or there may be several successive ovulations from the same ovary. In the fur seal, *Callorhinus ursinus cynocephalus* (Walbaum), Enders *et al.*[3] found that a single ovum is ovulated annually from alternate ovaries, as shown by the persistent remains of the corpus albicans. The pattern of ovulation between right and left ovaries remains to be determined for the Uganda kob.

Implantation occurred uniformly in the right horn of the uterus, as indicated by the presence of the fœtus and the number of cotyledons in each horn (Table 1). Chorionic attachments to uterine caruncles occurred in the left uterine horn when growth of the conceptus was sufficiently advanced. Unilateral

Table 1. FREQUENCY OF OVULATION BETWEEN RIGHT AND LEFT OVARIES; NUMBER OF COTYLEDONS IN GRAVID AND NON-GRAVID UTERINE HORNS IN UGANDA KOB, *Adenota kob thomasi* (P. L. SCLATER)

Phase of reproduction	No. of animals	Site of implantation		Larger ovary		Mean No. of cotyledons (range in parentheses)	
		Right	Left	Right	Left	Right horn (Gravid)	Left horn (Non-gravid)
Pregnant	116	116	0	57	59	14·0 (8–20)	7·6 (3–12)
Non-pregnant (lactating)	39	39	0	18	21	15·0 (10–21)	7·2 (5–10)
Non-pregnant (non-lactating)	5	5	0	2	3	15·0 (13–16)	7·0 (6–8)
Total	160	160	0	77	83	14·9 (8–21)	7·4 (3–12)

implantation appears to be a phenomenon that is unique in the Uganda kob. Since about 50 per cent of the ova are released from the left ovary, trans-uterine migration of the ovum or embryo must occur. This does not preclude the possibility of trans-peritoneal migration of the ova, although this route seems less likely. Trans-uterine migration has been recorded in the mink, *Mustela vison* Schreber[4]; the raccoon, *Procyon lotor* (L.)[5]; and the skunk, *Mephitis mephitis nigra* (Peale and Palisot de Beauvois)[6]. In sows, Hafez[7] found 41 per cent migration of ova on the basis of excess of ovulation sites over the number of implantations in the corresponding uterine horn. The physiological significance of unilateral implantation is not understood. E. M. Amoroso (personal communication) has shown that the distal portion of the uterus in the cat is more favourable for implantation than the proximal end. Possibly the endometrium of the right uterine horn provides the most favourable site for implantation in the Uganda kob.

One case (No. 47) of twins was discovered by W. O. Pridham, game ranger, Uganda Department of Game and Fisheries, immediately after parturition. Although the fawns (1 male and 1 female) were fully haired and approached mean parturition weight, they were dead. The female was shot while the extra-embryonic membranes were still retained in the uterus. At autopsy it was found that both fœtuses had been in the right horn of the uterus, and two corpora lutea were present in the right ovary.

The results presented here were obtained during a Fulbright appointment to Uganda. I am indebted to Prof. E. M. Amoroso of the Royal Veterinary College (University of London) for encouragement in this work. A. C. Brooks, biologist of the Uganda Department of Game and Fisheries, transmitted Prof. Amoroso's ideas for field collection of the data and assisted with most of the field work. Eleven of the Uganda kob were collected by I. O. Buss, professor of wildlife management, Washington State University.

Experimental Elimination of *Trypanosoma melophagium* Flu from its Hosts the Sheep and the Ked, *Melophagus ovinus* (L.)

Trypanosoma melophagium Flu is a non-pathogenic parasite of sheep, and its intermediate host is the sheep ked[2]. The parasite is world-wide in its distribution and is found wherever there are keds[1]. Infection of sheep usually takes place via the oral mucosa following ingestion of infected keds[2,4]. If sheep are treated to destroy keds, it is several months before the flagellates disappear from the host's blood. I[3] reported the death of large numbers of keds due to blockage of the midgut by masses of crithidia. Control over the trypanosome infection would be a useful tool for investigating this phenomenon further. The organism is not trans-ovarially transmitted in the ked[2] and thus flagellate-free insects should be easy to obtain.

Infected populations of keds on sheep were destroyed by spraying with 0·5 per cent toxaphene or malathion 6–8 weeks in advance of experiments to avoid residual toxicity to keds.

A week before re-infestation, sheep were given quinapyramine sulphate ('Antrycide', Imperial Chemical Industries, Ltd.), 8 mgm./kgm. subcutaneously. Sheep were infested with puparia which had been disinfected in 1 per cent mercuric chloride. Effectiveness of the drug in suppressing trypanosomes in the blood was checked weekly by dissecting 4–6 keds from each animal, wet-smearing the posterior midgut beneath a coverslip, and examining for crithidia under high dry magnification.

Lower doses of 'Antrycide' were not completely effective, and infection appeared in some keds within a few weeks. Higher doses caused toxic symptoms and occasionally death in sheep. At 8 mgm/kgm., trypanosome-free units can be maintained for several months provided there is no opportunity for re-infection. Sheep should be housed separately in clean quarters which have not recently contained infected animals. Even when trypanosome-free sheep were kept 50 ft. from infected sheep in the same barn, infection appeared in keds within a few weeks. This suggests that the infective forms present in ked fæces may be air-borne and may enter the sheep via the respiratory mucosa as well as by the oral route.

Culicoides adersi Ingram and Macfie, 1923, a Presumed Vector of *Hepatocystis* (= *Plasmodium*) *kochi* (Laveran, 1899)

MONKEYS of tropical Africa are well known to harbour a malaria parasite *Hepatocystis* (= *Plasmodium*) *kochi*, characterized by the presence of gametocytes only in the blood, and by the occurrence of schizogony in the form of macroscopic merocysts in the liver. As a malaria parasite, its vector was suspected for a long time as being a mosquito and several attempts were made experimentally and in Nature to incriminate these insects[1,2]. All failed, not altogether unexpectedly, when it was shown[3] that the parasite

Table 1. ATTEMPTS TO INFECT MONKEYS WITH SPOROZOITES FROM *Culicoides adersi*

Species of monkey	Serial No.	Inoculum	Route	Date	Result	Remarks
aethiops	35	15 positive glands	Subcutaneous	4.9.60	Negative for 7 months	Suspensions ? viable
aethiops	28	27 positive glands	Subcutaneous	28.9.60	Monkey died after 1 month; negative	Suspensions ? viable
aethiops	50	16 positive glands	Subcutaneous	30.9.60	Negative for 6 months	Suspensions ? viable
aethiops	30	4 positive midges	Bite	28.9.60	Gametocytes appeared on 1.2.61	
aethiops	31	Suspension of 69 midges (heavily positive batch)	Intravenous	6.1.61	3	Garnham technique
rhesus	23	Suspension of 21 midges (heavily positive batch)	Intravenous	7.1.61	3	Garnham technique

belonged not to the family Plasmodiidae but to the Haemoproteidae in which the sporogonic cycle was known to take place in *Simulium*, *Culicoides* and hippoboscids, but never in mosquitoes. The search was therefore widened to include other arthropods and a range of species was examined[3], but again with negative results. There was a slight indication that midges might be concerned, and in July 1959 an attempt was made to test this hypothesis in East Africa in a place where the monkeys were heavily infected with the parasite. We selected Port Reitz on the mainland near Mombasa, and worked at a small field laboratory conveniently situated in the middle of the area.

Heavily infected *Cercopithecus aethiops* monkeys were obtained, anæsthetized with 'Sernyl' (Parke Davis) and exposed to the bites of *Culicoides adersi* at dawn and dusk in the mangrove swamps, where these insects abound during the spring tides. Simultaneously, *C. adersi* were allowed to feed on human bait, and all the specimens were kept singly in tubes 2 in. × $\frac{1}{2}$ in. at a relatively uniform temperature (about 80° F.) in the laboratory. They were supplied with dilute glucose solution from the second day onwards on filter paper 'wick'.

Oökinetes were found in smears of the gut contents 20 hr. after the infective feed, but at first no later stages were detected. Then in August 1959 one of us (M. I.) found sporozoites in the salivary glands of a midge which had fed on an infected monkey 13 days before. Later dissections revealed a high rate of infection in the experimental insects, but a much lower incidence in the controls which had fed on man. Thus during August 1959–January 1961, the salivary glands and guts of 1,928 *C. adersi*, which had fed on an infected monkey 5–15 days previously, were examined and 568 or 29·5 per cent were found to show sporozoites. At the same time, 247 control midges which had fed on man 5–15 days previously were examined and 4 or 1·6 per cent were found to contain sporozoites. All these insects were caught in the wild, and an infection-rate of 0·2 per cent (4 in 2,400) was found in unfed specimens, dissected on the day of capture.

The sporozoites were curved bodies, about 13μ in length, and usually had a single, solid bead-like nucleus, often placed nearer the pointed end of the sporozoite; the other end was blunt. In serum Locke fluid, the sporozoites showed a peculiar type of movement, one-half contracting with a snake-like motion, yet rather jerkily.

The sporozoites were first detectable in small numbers around the mid-gut and Malpighian tubules 5 days after an infective feed; they tended to increase during the sixth and seventh days when the salivary glands became invaded. Infection persisted in the glands for at least 17 days, but declined in intensity after the thirteenth day. It was difficult to be sure about the latter point, because the majority of infections at any time were light; it was quite exceptional to find, for example, several hundred sporozoites.

Attempts were made to transmit the infection to clean monkeys and the results are shown in Table 1. A vervet monkey (No. 30) was bitten by four midges on September 28, 1960; the salivary glands were then extracted and all four were found to contain sporozoites. The blood of the monkey was examined twice a week until February 1, 1961, when parasites were first detected. There is thus a pre-patent period of four months.

Many of the batches of midges which had fed on *kochi*-infected monkeys were found to be infected in a range of 60–90 per cent, while controls fed on man were almost entirely negative (4/247). We have sought in vain for any explanation other than the obvious one that the midges were acting as vectors of *H. kochi*.

The experiments were tainted because we were compelled to use wild-caught flies, and they are therefore subject to the criticism that the sporogonic cycle may have had an extrinsic origin. If so, what could this have been? *Culicoides* spp. have been shown to be the natural vectors of *Haemoproteus* in Canadian birds[4] and we found *Haemoproteus* in weaver birds in the mangrove swamps where we were working. Nevertheless, if the sporozoites had been of avian origin, the infection-rate in the controls should have been similar to that in midges fed on monkeys, but instead of 60 or 70 per cent it was 1·6 per cent, while in unfed wild-flies dissected on the day of collection, the incidence was 0·2 per cent. Keeping the flies for a week or longer would, of course, allow natural infections to mature and the rate would increase accordingly (that is, to 1·6 per cent). It is, therefore, probable that the natural rates represented true *H. kochi* infections acquired in the field, because monkeys are said to descend from the second growth forest, scrub or plantations to the mangrove swamps by the creeks, where they would be attacked by midges.

The rapid cycle of sporogony (5 days), the low production of sporozoites, their gradual release from oöcysts, and the small size of the oöcyst, are all features[5] of the developmental cycle of two other common members of the family—*Leucocytozoon* and *Haemoproteus*, and as *Hepatocystis* belongs to this family (Haemoprotedae) it is not surprising that it also should exhibit all or most of these features. Canadian workers took a long time to identify with certainty the oöcysts of both *Leucocytozoon* and *Haemoproteus*; they are much smaller than in *Plasmodium* and it is not altogether surprising that, so far, we have been unable to find them in *Hepatocystis*.

Slight differences can be seen in the sporozoites of the different genera as follows: *Leucocytozoon*, 9–13μ in length; more pointed at one end. *Haemoproteus* (*Culicoides* type), 10–14μ; ends similar.

Haemoproteus (*Lynchia* type), 9μ or less; more pointed at one end. *Hepatocystis*, 13μ; more pointed at one end. *Plasmodium*, 10–14μ; ends similar.

The morphology of the sporozoite found in *C. adersi* is another indication that they are not *Haemoproteus*. The vector of *Leucocytozoon* is a *Simulium* which, presumably, excludes this organism from the argument.

We were afraid at first that Koch's '*Plasmodium*' was not going to conform with his 'Postulates'; the monkeys which were inoculated with sporozoites from slide preparations of glands are still negative, but the monkey which was bitten by infected *Culicoides* has now, after 4 months, become positive. The tissue forms of *Hepatocystis* have a diameter of about 40 times that of a liver schizont of *Plasmodium*; the pre-patent period of the latter is 5–10 days, so it is scarcely surprising to find that it takes nearly that number of months for *Hepatocystis* to mature in the liver.

We report these findings in the belief that the midge is the vector of *Hepatocystis*, and in the hope that similar experiments will be made elsewhere in the Old World where species of *Hepatocystis* are common in various animals.

Azulene Derivatives as Plant Growth Regulators

Among the many hundreds of compounds examined for effects in promoting cell elongation, very few having activity do not have a ring structure possessing aromatic character[1]. Thus it is logical to look for activity in compounds having 'non-classical' aromatic rings such as derivatives of azulene and ferrocene. The azulene compounds are of particular significance since this ring system occurs frequently in essential oils and plant tissue, and anti-inflammatory, anti-allergic, bacteriostatic, cancerostatic and anti-arthritic activities have been claimed for azulenes[2].

Ferroceneacetic acid, ferrocenediacetic acid and ferrocenepropionic acid are all completely inactive in cell elongation as shown by their lack of effect on 3-mm. segments of *Avena* coleoptiles[3]. However, as shown in Table 1, some azulene derivatives have high activity in promoting cell elongation. Since azulene compounds are isomeric with corresponding naphthoic compounds, it would be expected that a similar pattern of activity would be found in the two series and the lack of activity of azulene-1-carboxylic acid and 1-naphthoic acid in coleoptile tissue[4] is in agreement. However, many reports have assigned activity to 1-naphthoic acid in pea tissue[4–6] and it was, therefore, of interest to examine the effects of the azulene compounds on elongation of 5-mm. segments of stem tissue of pea. Azulene-1-carboxylic acid does not promote elongation in pea tissue although 1-naphthoic acid is very effective as shown in Fig. 1. This finding demonstrates a difference in the plant substrate in pea tissue and *Avena* coleoptile tissue. Whether the difference in activity of the azulene-1-carboxylic acid and 1-naphthoic acid is the result of a steric or electronic difference in the 7- and 6-membered rings remains to be established. Although azulene-1-acetic acid and 1-naphthoic acid at low concentrations have much less effect on elongation than indole-3-acetic acid or α-naphthaleneacetic acid, at high concentrations their effects become equivalent.

Table 1. Percentage Elongation of Coleoptile Segments in Solutions of Azulene Derivatives and Naphthoic Acid as compared with Percentage Elongation in Water

	Molar concentration			
	10^{-6}	5×10^{-6}	10^{-5}	5×10^{-5}
Azulene-1-acetic acid	0	+12	+22	+31
Azulene-1-acetonitrile	+8	+17	+16	+11
Azulene-1-carboxylic acid	0	0	0	−8
1-Naphthoic acid	0	0	0	0

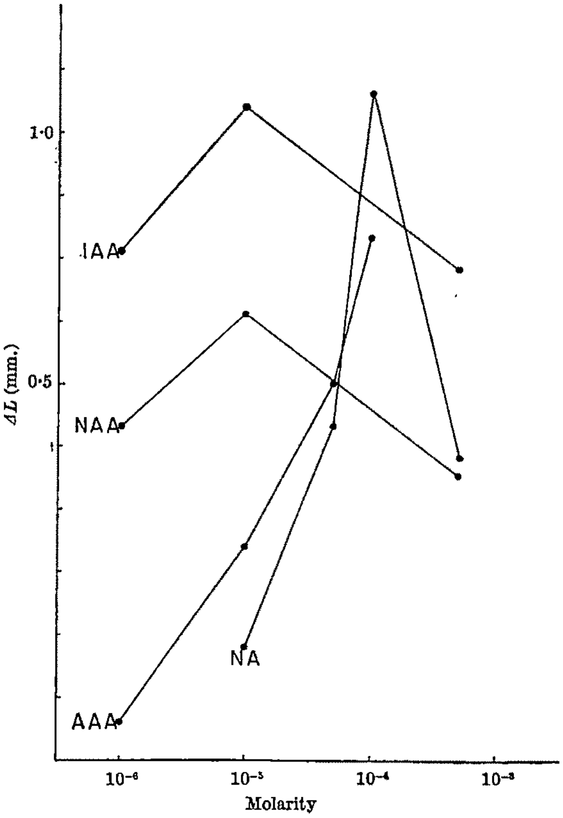

Fig. 1. Growth in length induced by indole-3-acetic acid (IAA), α-naphthaleneacetic acid (NAA), azulene-1-acetic acid (AAA) and 1-naphthoic acid (NA) of segments of pea stem tissue

Azulene-1-acetonitrile is totally inactive in promoting elongation of pea tissue and is thus similar to indole-3-acetonitrile, which the pea tissue, unlike *Avena* coleoptile tissue, is unable to convert to the active acid[7].

It is difficult to decide how much activity should be expected for azulene-1-acetic acid in comparison with α-naphthaleneacetic acid. According to the two-point attachment hypothesis[1,3,6,8] such growth regulators react with an electron-rich point on a plant substrate through a position on the ring which is ortho to the carboxyl group of the regulator. It is well known that the 8-position in azulene is very susceptible to attack by electron-rich reagents, and high activity of azulene-1-acetic acid is therefore not surprising. Reactivity indices (approximate superdelocalizability) calculated by Koshimiza, Fujita and Mitsui[6] according to the frontier electron theory[8] indicate that the 8-position in 1-naphthoic acids is the site of reaction on the ring. Evidence for the involvement of the 8-position of azulene compounds in the reaction also exists in the sterically similar naphthalene situation where the 8-position seems more important than the 2-position, as Burstrom *et al.*[9] have shown 8-chloronaphthalene-1-acetic acid is much less active than α-naphthaleneacetic acid even though chlorine is normally an activating group. Whether or not the small activity at low concentrations is the result of the greater instability of the azulene ring or some basic structural unsuitability of the molecule is unknown.

The fact that the non-alternate aromatic system, azulene, is active in promoting elongation suggests that other such systems should be investigated.

We are indebted to Prof. Arthur G. Anderson, jun., of the University of Washington, for the azulene derivatives examined in this investigation, and to Prof. Kenneth L. Rinehart, jun., of the University of Illinois, for the ferrocene derivatives.

ENTOMOLOGY

The Function of the Paleal Pegs of Corixidae (Hemiptera Heteroptera)

THE Corixidae are a family of aquatic bugs living on the habitat bottom. The front legs of both sexes are used for collecting food, the tarsi (or paleæ) being highly specialized for this purpose. The middle legs have retained their ambulatory form, and the long claws are used for anchoring the insect to the habitat bottom during feeding. The hind-legs are used for swimming, the tibiæ and tarsi being specially flattened for this purpose.

The front legs sweep a food-bearing water current towards the mouth by means of the longitudinal rows of setæ on the paleal edges (Fig. 1, *c* and *d*). In the males, the inner surface of each palea bears a longitudinal row of pegs, which is represented in the female by a row of short setæ (cf. Fig. 2 and Fig. 1, *b*). Kirkaldy[1] suggested these pegs were used for stridulation; but the work of von Mitis[2] has shown that sound is produced in other ways. The form of the male paleæ and the arrangement of the pegs is fairly constant for each species and these features have been used for species identification in British taxonomic works by Saunders[3], Butler[4], Macan[5] and by Southwood and Leston[6].

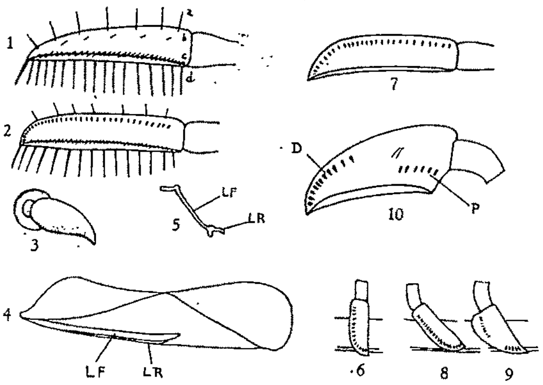

Fig. 1. Median surfaces of the tarsus and tibia from the front right leg of *Corixa punctata* (female). Fig. 2. Median surfaces of the tarsus and tibia from the front right leg of *Corixa punctata* (male). Fig. 3. Enlarged view on a paleal peg of *C. punctata*. Fig. 4. Hemielytron of *C. punctata*. Fig. 5. Enlarged view of a transverse section of the lateral flange to show outer ridges. Fig. 6. Left leg and lateral flange of *H. sahlbergi* during copulation. Fig. 7. Median surface of the tarsus and tibia of the front leg of *H. sahlbergi* (male). Fig. 8. View of left leg and lateral flange during copulation of a hypothetical species with a curved tibia. The paleal pegs would not grip the ridges of the lateral flange. Fig. 9. Lateral view of left front leg and lateral flange of *Sigara distincta* during copulation. Notice the distal row of paleal pegs is rotated to grip the flange ridges. Fig. 10. Median surfaces of the tarsus and tibia of *Sigara distincta* (male). (In Figs. 6, 8 and 9 the paleal pegs are drawn as though they could be seen through the palea.)

a, *b*, *c*, *d*, rows of paleal setæ; *D*, distal row of paleal pegs; *LF*, lateral flange; *LR*, longitudinal ridge of lateral flange; *P*, proximal row of paleal pegs

The true function of the paleal pegs may be observed during copulation. When mating, the male darts on to the back of the female which he holds by pressing his head against her pronotum—the frons of the male being flattened or even concave for this purpose. In addition the front legs are stretched sideways and the inner surface of each palea is extended over the lateral flange of the hemielytron on the corresponding side (Fig. 6). The paleal pegs are composed of a circular base on which is a short peduncle supporting a larger conical structure. The cone is not vertical, but bent towards the centre of the palea (Fig. 3). The lateral flange of the hemielytron (Fig. 4) is slightly concave in transverse section and the outer margin is raised into a longitudinal ridge, which in the region of the metathorax is enlarged and folded outwards to form a longitudinal grip (Fig. 5). When the front legs of the male are extended sideways, the distal pegs become caught under the curved longitudinal ridge of the lateral flange on the hemielytron and the two sexes are thus able to swim and surface while firmly attached to one another in this way.

In *Corixa punctata* (Illig.) the paleal pegs form a single row, which is curved distally to run slightly transversely across the palea (Fig. 2) and this appears to be a primitive arrangement in the Corixidae. Primitively the tibia is straight; but in the more specialized species tends to become curved inwards to aid food-collecting. If the paleal pegs retained their primitive arrangement, their effectiveness in holding the female would be reduced (Fig. 8), but changes in the tibia are associated with a broadening of the male palea and the row of paleal pegs is distally rotated so as to retain the original relationship with the hemielytral ridges. As a result of these changes, the row of paleal pegs tends to become broken into a distal functional row and a proximal row in which the pegs tend to become vestigial. These changes are well illustrated by a comparison of *Hesperocorixa sahlbergi* (Fieb.) (Fig. 7) and *Sigara distincta* (Fieb.) (Fig. 10).

At first sight the form of the male paleæ and the arrangement of the paleal pegs would appear to be non-adaptive; any one arrangement of paleal pegs being as effective as any other for gripping the female. But the front legs are used for other functions, particularly feeding, and a study of the functional morphology of the front legs shows that the form of the male paleæ and the arrangement of the pegs is of great functional significance, as well as being a valuable taxonomic feature at the species-level.

Atypical Spermiogenesis in *Thermobia domestica*, a Thysanuran Insect

IN a recent communication, Bawa[1] has again put forward the hypothesis of a typical sperm in *Thermobia domestica*. However, I have shown[2], with some electron photographs of *Petrobius maritimus*, that the centriole and the acrosome are in their normal positions. The acrosome is a scoop-shaped body at the anterior end of the nucleus which forms a projecting tube. What Bawa has called the acrosome is probably another body, the centriole adjunct[3], which encloses a centriole and gives rise to the flagellum. In Thysanura, no division of the centriole occurs, and as such it is a fixed body on the posterior aspect of the nucleus. These observations are further strengthened by the detailed cytochemical reactions obtained by me, the results of which will be published elsewhere.

As regards the 'adnuclear fold' or the 'lateral fold', it is very clear from the electron photographs that the fold is not a continuation of the flagellum as it does not possess the typical fibrillar structure. On the contrary it is an intra-nuclear body of unknown significance. This body is an easily followed structure in X-irradiated *Petrobius*[4]. It also differs with the flagellum in chemical constitution.

Finally, I again stress that the sperm of thysanuran is a typical flagellate sperm and does not show any deviation from the normal patterns.

R. S. MATHUR

Zoology Department,
Trinity College, Dublin.

[1] Bawa, S. R., *Nature*, 188, 1132 (1960).

[2] Mathur, R. S., *Nature*, 188, 164 (1960).

[3] Gatenby, J. B., and Tahmisian, T. N., *La Cellule*, 60, 105 (1959).

[4] Mathur, R. S., *Proc. Roy. Irish Acad.*, B (in the press).

MATHUR (preceding communication and ref. 1), in his communications, has again stressed that the thysanuran sperm is a typical flagellate one, having the acrosome and the centriole located at the proximal and distal end of the nucleus. I disagree with him and have the following comments to make in this context.

Mathur's[1] report is incomplete inasmuch as he does not mention (1) the name of the insect, (2) the stage of spermiogenesis electronmicrograph 1 represents and (3) the magnification of the two electron micrographs. I may add that I am unable to interpret his electronmicrograph 2. Furthermore, if I am interpreting correctly, Mathur's electronmicrograph 1 is a spermatid of a thysanuran. After scrutinizing scores of electronmicrographs of *Thermobia* spermatids[2], it is safe to point out that Mathur's acrosome *A* is actually the nucleus which shows nuclear pores at places, and his nucleus *N* is unmistakably a typical mitochondrial nebenkern revealing badly damaged cristæ. Mathur, however, does not mention anything about the mitochondria. It has been reported[2] that a typical mitochondrial nebenkern is formed in *Thermobia* and other thysanurans, and it remains an integral part of the mature spermatozoan. The structures F_1, F_2 and F_3 in Mathur's[1] electronmicrograph 1 do not reveal any structural detail to be identified as parts of the flagellum cut at different places. He also fails to make reference to bodies labelled as *M* in electronmicrograph 1. It is not clear whether bodies *F*, *M* identified by him in the upper right corner of electronmicrograph 1 are inclusions in the same cell referred to in the micrograph or are located in an adjacent cell. Structures *CA*, *M*, F_1, F_2 and F_3 probably are the microbodies or lipid elements, as such inclusions are invariably observed in the spermatids of *Thermobia*. So far as I can understand, the only structure identified correctly by Mathur[1] in electronmicrograph 1 is the Golgi material, *G*.

In *Pterobius* spermatid, Gatenby and Mathur[3] using light microscopy were unable to establish the correct nature of the 'adnuclear' or 'lateral fold'. This structure, according to Mathur, is the 'intranuclear' body of unknown significance. However, this 'intranuclear body' is seen to consist of the tail flagellum and the two mitochondrial nebenkern ribbons[1,4,5]. Electron microscopy[2] of *Thermobia* clearly indicates the composite nature of this intranuclear body. In favourably cut ultra-thin sections of *Thermobia* spermatids, one can discern tail filament complex and the mitochondrial cristæ in the nebenkern ribbons. It is important to mention also that the nucleus, mitochondrial nebenkern and the tail filament complex are seen to be disposed adjacent to each other. Such a unique spatial arrangement is especially clear in the cross-sections. Finally, there is evidence[2] that the acrosome occupies the basal end of the sperm head and that it is derived from the Golgi dictyosomes. The centriole is not embedded in the 'centriole adjunct' and it moves around the nucleus until it lies toward the apical end of the nucleus. Thus there is no reason to confuse the 'centriole adjunct' of Gatenby *et al.*[6] with the acrosome of *Thermobia domestica* spermatozoan.

This work was supported in part by the Population Council, Inc., New York.

GENETICS

Mitotic Haploidization by Treatment of *Aspergillus niger* Diploids with *para*-Fluorophenylalanine

In genetic analysis based on mitotic segregation[1-4] an important step is the recovery of haploid segregants from heterozygous diploids. This has been done until recently by laborious or complicated techniques[4,5]. I am indebted to Dr. G. Morpurgo, of the Istituto Superiore di Sanità, Rome, for informing me and permitting me to make use of his discovery that treatment with *para*-fluoro-phenylalanine of diploids of *Aspergillus nidulans* leads to wholesale segregation (this discovery was made known in the privately circulated *Aspergillus News Letter*, p. 10, No. 2, Spring 1961). In an extensive work expanding the formal genetical analysis—via mitotic segregation—of the fungus *A. niger*[6], I have applied this treatment to diploids of this asexual species.

The amino-acid analogue DL-*para*-fluoro-phenylalanine was incorporated in standard complete medium[7] to a final concentration of 1/10,000 w/v and conidia from diploid strains heterozygous for a number of colour and nutritional markers were plated on the surface. At this concentration of the analogue, the viable counts remain the same as on standard complete medium, but the rate of growth is much slower (diameter of colonies after 5 days: 0·5–1 cm. instead of about 10 cm.) and sporulation is very poor. These colonies produced sectors, the rate of growth and sporulation of which was about the same as on normal complete medium. After 10 days, conidia of these sectors were streaked on complete medium, classified for ploidy on the basis of the diameter of their conidia and tested for requirements. All of them turned out to be haploid and of all possible recombinant types between independent markers.

As an example, a heterozygous diploid with black heads (wild-type) and prototrophic was synthesized from two haploid strains: one fawn (*a*) and the other olive (*o*) (two recessive non-allelic markers belonging to the same linkage group). The two strains also differed in four recessive nutritional requirements and the genotype of the diploid formed from them was:

$$\frac{a \qquad +}{+ \qquad o} \qquad \frac{+}{hist} \qquad \frac{+ \qquad gua_7}{lys_4 \qquad +} \qquad \frac{meth_7}{+}$$

The vigorously growing sectors produced by this diploid were either fawn or olive. To minimize clonal effects, only one sector of each colour (fawn or olive) was picked from a colony. The 74 sectors so isolated, 38 fawn and 36 olive, fell into the 8 possible classes of segregants and recombinants in respect of the four other markers belonging to three different linkage groups.

That haploidization, as a consequence of *para*-fluoro-phenylalanine treatment, occurs by successive losses of chromosomes—as found by Käfer[4] for *Aspergillus nidulans* in the case of 'spontaneous' haploidization—is shown by the following evidence: The results just mentioned are obtained by isolating vigorously and well-sporulating sectors from diploid colonies grown in the presence of the analogue for ten days. If small groups of hyphal tips are taken from diploid colonies only after 48 hr. of growth in the presence of the analogue and transferred to normal medium, they produce sectors in which more and more nutritional markers segregate as growth proceeds.

On *para*-fluoro-phenylalanine the amount of growth intervening between the original diploid mycelium and the completely haploid sectors is relatively small, indicating a selective effect against diploids and disomics. I interpret this to mean that loss of individual chromosomes in a haploid leads to no further divisions of that nuclear lineage, while in a diploid or disomic stunted growth may go on.

The availability of a treatment which produces wholesale haploidization is a very valuable addition to the techniques for genetical analysis via mitotic segregation.

Hybrids between *Solanum bulbocastanum* and *Solanum cardiophyllum*

The Mexican diploid tuberous *Solanum* series Bulbocastana and Cardiophylla are important potential sources of genes for resistance to late blight of potatoes. Niederhauser and Mills[1] noted field immunity in certain clones of *S. bulbocastanum* in their field trials in Mexico. No investigator has hitherto reported hybrids between these series and the Tuberosa. A knowledge of the crossability relationships of the Mexican diploid species may be useful in overcoming their apparent isolation.

Extensive collections were made of *S. bulbocastanum* Dun. and *S. cardiophyllum* Lindl. throughout their ranges in Mexico during 1956 and 1957. The collections of *S. cardiophyllum* were comprised of *S. cardiophyllum sensu stricto*, *S. ehrenbergii* (Bitt.) Rydb. and *S. cardiophyllum* var. *endoiodandrum* Bitt. Seed set occurred from crosses between *S. bulbocastanum* (C-238) and *S. cardiophyllum* (C-297), and in the reciprocal cross between *S. ehrenbergii* (C-370) and *S. bulbocastanum* (C-194).

The hybrid plants from both crosses showed in their seedling stages the unifoliate characteristic of the *S. bulbocastanum* parent. As they approached the flowering stage, they presented the aspect of a compound-leaved *S. bulbocastanum*.

Although the hybrids produced a high percentage of stainable pollen, it was not always possible to obtain fruit and seed set by sibling pollinations within the families *C*-238 × *C*-297 and *C*-370 × *C*-194. The inter-family cross-pollinations attempted were successful in both directions. This observation suggests a repetition of the intra-family cross-incompatibility noted by Graham *et al.*[2] in *S. bulbocastanum*.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Tuesday, May 23

University of London (at Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. B. G. Neal: "Some Problems in Plasticity" (Inaugural Lecture).

Society of Chemical Industry, Plastics and Polymer Group (in the Film Theatre of Shell-Mex House, Strand, London, W.C.2), at 6 p.m.—Annual General Meeting. Mr. P. S. Adamson: Chairman's Address.

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Annual General Meeting. 7 p.m.—Presidential Address.

Wednesday, May 24

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Anniversary Meeting. Prof. C. F. A. Pantin, F.R.S.: "On the Teaching of Biology" (Presidential Address).

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. C. D. Darlington, F.R.S.: "Cousin Marriage".*

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Annual General Meeting, followed by Mr. T. McLachlan: "Some Historical Notes on Food Technology".

British Psychological Society, Medical Section (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 8.30 p.m.—Symposium on "The Saboteur in Group Psychotherapy". Speakers: Dr. Malcolm Pines, Dr. Robin Skynner and Dr. S. Resnik.

Thursday, May 25

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Charles Darwin, F.R.S.: "The Gravity Field of a Particle. II". Mr. B. Thwaites: "The Aerodynamic Theory of Sails. I: Two-dimensional Sails".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. K. R. Hyde, Prof. P. L. Robinson, Mr. M. J. Waterman, and Dr. J. M. Waters: "Reaction of Beryl with Sodium Fluorosilicate Used in Extracting Beryllium from the Mineral"; Dr. J. S. Tooms and Mr. S. Kaewbaidhoon: "Dispersion of Tin in Soil over Mineralization at Sungei Lembing, Malaya".

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. Wilfred Brining: "Bauxite and its Importance to the Commonwealth" (Henry Morley Lecture).

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. A. Broughall: "Electric Traction".

Institut Français du Royaume-Uni (at Queensberry Place, London, S.W.7), at 6.15 p.m.—Dr. Tomatis (Paris): "Phonation et Audition".*

Friday, May 26

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mr. Denis McMahon: "An International Study of Military Training".

Scientific Publications Council (at the Ciba Foundation, 41 Portland Place, London, W.1), at 6 p.m.—Discussion Meeting on "Time-Lag in the Publication of Scientific Manuscripts".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or **Assistant Lecturer in Bacteriology**—The Registrar, The University, Leeds 2 (May 27).

Lecturer (with an honours degree) **in Physics**—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (May 27).

Research Assistant (with a good degree in chemistry or biochemistry and preferably some research or industrial experience in the lipid field) **in Lipid Chemistry**—The Registrar, Brunel College of Technology, Woodlands Avenue, Acton, London, W.3 (May 27).

Demonstrator (Assistant Lecturer) in Physiology—The Registrar, The University, Leeds 2 (May 29).

Lecturer in Mathematics—The Principal, Borough Road College, Isleworth, Middlesex (May 29).

Assistant Lecturer in Physics—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 31).

Lecturer (graduate with medical qualifications) **in Anatomy**—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 31).

Lecturer (with special interests in physical or inorganic chemistry) **in the Department of Chemistry**—The Secretary, The University, Edinburgh (May 31).

Senior Lecturer/Lecturer in Geography at the University of New England, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, May 31).

Reader in Mathematics at Westfield College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 8).

Lecturer or **Assistant Lecturer** (medically qualified or otherwise) **in the Department of Physiology**—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (June 19).

Chair of Geography at University College, Ibadan, Nigeria The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 20).

Lecturer (preferably with a special interest in either vertebrate zoology or genetics) **in the Department of Zoology**, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 20).

Assistant Under-Librarian (graduate in science or with experience of library administration)—The Librarian, University Library, Cambridge (June 22).

Assistant Professor (Poultry Genetics) (with a Ph.D. or equivalent in genetics, and preferably training in biochemical genetics) **in the Department of Animal Science**—Head, Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (June 30).

Chair of Education in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong and London, June 30).

Reader in Fuel Science in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (June 30).

Research Fellow (Organic Chemist) in the Department of Medical Chemistry, John Curtin School of Medical Research, Australian National University, Canberra, to work with Prof. Adrien Albert or Dr. D. J. Brown on problems in the pyrimidines, pteridines or other hetero-aromatic series—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, June 30).

Research Fellow (with a Ph.D. degree) and a **Research Student** (with an M.Sc. or an honours degree) **in the Department of Physics**, to participate in the research of a small group working on problems of brittle fracture and on the influence of absorbed substances on the strength of solids such as silica and tungsten carbide—Prof. F. R. N. Nabarro, c/o The Registrar, University of the Witwatersrand, Milner Park, Johannesburg, South Africa (June 30).

Senior Lecturer or **Lecturer in Physics** at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, July 31).

Senior Lecturers and **Lecturers** (with qualifications in either pure or applied mathematics) **in Mathematics** at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, August 9).

Assistant Lecturer in Organic Chemistry—The Registrar, The University, Manchester 13.

Assistant Professor (Ph.D. or M.B.) **in Pharmacology**—Prof. M. F. Murnaghan, University of Ottawa, Ottawa, Ontario, Canada.

Biochemist, to supervise all chemical procedures and to conduct research in fields related to blood transfusion in consultation with the Director—The Director, Red Cross Blood Transfusion Service, 409 Adelaide Street, Brisbane, Queensland, Australia.

Chemist or **Biochemist** (with an honours degree, a good knowledge of general chemistry and an interest in protein chemistry), to investigate the constituents of animal connective tissue together with related enzyme systems—The Director, Low Temperature Research Station, Downing Street, Cambridge.

Chief Laboratory Technician (with the City and Guilds Final Certificate in Laboratory Technology (or accepted equivalent) and previous experience in physiology, pharmacology or biochemistry, including the care and maintenance of equipment and apparatus) **in the Department of Physiology and Pharmacology**—Head of the Department of Physiology and Pharmacology, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

Curator (preferably with experience in museum administration, as well as general scientific knowledge, especially in biological fields) of the Coryndon Museum, Nairobi, Kenya—The Secretary, Coryndon Museum, P.O. Box 658, Nairobi, Kenya, East Africa.

Junior Biochemist, Basic grade (with an appropriate science degree or associateship of the Royal Institute of Chemistry) **in the Chemical Pathology Laboratory**, Nottingham General Hospital—The Group Secretary, Nottingham No. 1 Hospital Management Committee, General Hospital, Nottingham.

Master to teach Mathematics throughout the school—The Headmaster, Malvern College, Malvern, Worcs.

Research Students and **Assistants in the Department of Physics**—Prof. D. J. E. Ingram, Department of Physics, University College of North Staffordshire, Keele, Staffs.

Senior Mathematics Master—The Headmaster, Adams' Grammar School, Newport, Salop.

Technical Research Assistant in the Botany Department, to work with Prof. Street on the establishment of free cell cultures from higher plants—The Registrar, University College of Swansea, Swansea.

ACADEMIC FREEDOM IN SOUTH AFRICA

WHATEVER view may be taken as to whether South Africa should continue to be a member of the Commonwealth while her Government pursues the policy of apartheid, the withdrawal of South Africa from the Commonwealth can only be regarded, as the Prime Minister said in the House of Commons on March 22, as a very sad event; "sad because of what seems to us a tragically misguided and perverse philosophy which lies at the root of apartheid; sad because of the many people in South Africa . . . who would like it at least tempered and made more elastic and more humane; sad because this event marks the end of an association of our countrymen for more than a hundred years with Colonies formed in Capetown, Natal and elsewhere; sad because it is the end of a fifty-year connexion which began with a decision then hailed as an outstanding example of magnanimity after victory; sad because it makes a breach in a community which has a great part to play in the world".

The issue of apartheid in connexion with academic freedom has, of course, been discussed several times in these columns (see *Nature*, June 6, 1959, p. 1551). It has already created difficulties with which some scientists have been particularly concerned. It has to some extent jeopardized the contribution which South Africa could make to the work of the Scientific Council for Africa South of the Sahara and of the Commission for Technical Co-operation in Africa South of the Sahara, and it has struck a serious blow at the South African universities. With the best will in the world, it is unlikely that those difficulties will diminish in a South Africa outside the Commonwealth. As Mr. Duncan Sandys, the Secretary of State for Commonwealth Relations, rightly said in the debate in the House of Commons, we must not let it be thought that it makes no difference whether one is in or out of the Commonwealth. This Mr. Sandys reaffirmed on April 24 in introducing the Republic of South Africa Temporary Provisions Bill. In his recent speeches, Dr. Verwoerd has been giving the impression that South Africa's withdrawal will make no difference; but while there will be a general wish to maintain close relations with South Africa and particularly to do anything that may be possible to help those South Africans who cherish their ties with Great Britain and are opposed to Dr. Verwoerd's policy and action, the position has been greatly changed by that withdrawal.

The effect of withdrawal on scientific research in South Africa and on South Africa's co-operation in scientific and technical matters was not discussed in either House of Parliament; but in the debate on South Africa and the Commonwealth in the House of Lords on March 23, Lord Beveridge referred briefly to the universities. Lord Hailsham, in opening the debate, had pointed out that, while it would be idle to pretend that the withdrawal from the Commonwealth would not affect relations between the two countries, time alone would show how far-reaching that change would be. For that reason the Government had decided to introduce a standstill measure, so that we might have time to think in an atmosphere of friendliness and toleration exactly what our course should be.

Lord Hailsham referred particularly to our obligations to our South African fellow citizens in High Commission Territories, and said that we must maintain relations with the South African Government which permit us to discharge them honourably. In this connexion, however, it must also be remembered that the educational policy of the South African Government has already made it more difficult for the needs of those territories to be met by our existing arrangements, especially in respect of higher education. Questions of status and citizenship will also, as Lord Hailsham noted, require discussion in an atmosphere of calm.

Lord Beveridge, who stressed the importance of considering the interests of people of British descent and British outlook in South Africa, referred to the implications of the South African Government's policy of introducing racial discrimination into the open universities of Cape Town, the Witwatersrand and Natal. He regarded it as vital to the future of peace between coloured people and white people that these universities should be made open and self-governing and free from racial discrimination. Under the Extension of University Education Act of 1959, these universities cannot continue to accept non-white students without the written consent of the Minister, and up to the present, even while the non-white university colleges are being developed, the Minister has refused all but 2 out of 153 applications from Bantus.

That Act is a serious infringement of university autonomy which in itself could have disastrous consequences for the universities as well as for science and learning generally in South Africa. These consequences could perhaps be exaggerated, for a university is inevitably influenced by the kind of community in which it is situated, and university autonomy cannot be maintained in a community which does not understand its nature or seek to preserve it, however firm the safeguards against interference by Government; though it should be remembered that there is a considerable volume of opposition to the South African Government's policy within South Africa. No less serious, however, is the extent to which the Act shatters the South African university tradition by subjecting the whole of a university staff to appointment by a Minister and to control in all their university activities by Ministerial regulations and by a statutory code of discipline which stifles the academic conscience.

The South African Government's proposals were opposed at the time by the universities with noteworthy dignity and cogency, and in their opposition they had the unequivocably expressed support of the universities of the world. The South African Government, however, was quite unmoved by this opposition, and with the withdrawal of South Africa from the Commonwealth it must become increasingly difficult to assist the South African universities to sustain their old and high traditions of learning and investigation, even if they are still able to participate unhindered in the meetings of the universities of the Commonwealth. Only time can show to what extent they will find it more difficult to recruit staff of high standing, for either teaching or research. It is at least unlikely that outstanding investigators will be ready to enter institutions where such Ministerial restrictions on freedom of investigation and utterance are current; if the full effect is only felt as existing members of the universities reach retiring age, the ultimate result will be no less disastrous.

Leaving out of the discussion the needs of the coloured peoples of South Africa, which the South African Government proposes to meet by measures described by Lord Beveridge as utterly unworthy of being termed university education, it is a matter of doubt whether the South African universities, under these conditions, will be able to supply the scientists and technologists which the country needs to-day. Obviously they will be unable to supply the numbers required, for the exclusion of coloured races means that they can offer no contribution to the immense numbers of trained Africans that are required to deal with the urgent problems of development in Africa to-day. Any contribution to the expansion visualized at the Commonwealth Education Conference is likewise barred, and it is more than doubtful whether they will long continue to supply the white scientists and technologists of the high quality required. A system which strikes at the root of the free intercourse and communication on which scientific and technical advance depends, and forces South African workers to go to Britain or America to meet Africans of university standard and ascertain their views, as Dr. H. J. Grenville-Wells pointed out at the conference on university apartheid in November 1957, carries the seeds of its own decay.

The problem, however, is essentially to find some means of inducing the advocates of apartheid to realize the implications of its application in the universities as regards scientific and technical work, or professional work generally, and of considering the possibility of relaxation to avoid those untoward consequences. The English-speaking universities have protested with dignity and determination against this closure of their open doors, and the University of the Witwatersrand, in particular, not content with affirming the principle that a university is a place where men and women, without regard to race or colour, are welcome to join in the acquisition and advancement of knowledge, has dedicated itself to the maintenance of this ideal and to the restoration of its autonomy. Its members are fully aware that a university can only make its proper contribution to national life when it is assured of freedom to teach, to investigate, to discuss and to criticize, and that when deprived of any one of these the quality of its intellectual life will decline, creative work be stifled, research discouraged or discontinued, and ultimately the quality of its teaching become that of the school class-room. Nor are they under any illusions that time is on their side: unless their autonomy is regained before the new Act has its full insidious effect, their university status will be lost, perhaps irretrievably.

Sir Eric Ashby, who in *The Guardian* last year described some of the protests made by the English-speaking universities, finds some hope in the liberalism to be found among some Afrikaans-speaking intellectuals, although the four Afrikaans-speaking universities, the policy of which has been to enrol white students only, in public and officially subscribe to the policy of apartheid. Prof. B. B. Keet, of the University of Stellenbosch, and Prof. P. V. Pistorius, of the University of Pretoria, have both incisively condemned the Government policy, and probably the book, *Our Responsibility*, by the Hon. H. A. Fagan, formerly Chief Justice of South Africa, is even more influential. While it is unlikely that criticism even from such quarters will have much influence on the present South African Government, at this juncture of South Africa's withdrawal from the Commonwealth it is well to remember that the policy of apartheid finds its critics in South Africa among people of Dutch as well as of British stock.

The Act which strikes at the very existence of the South African universities has another effect. So far from extending university education, its immediate effect is to put higher education out of the reach of hundreds of non-whites. It is true that it established three so-called university colleges for Bantus and one for other non-whites, but so far they are out of reach of thousands of the students for whom they are professedly intended, and, apart from the legitimate doubts expressed by Lord Beveridge as to their academic calibre, there is no evidence that the South African Government is sincere in these constructive proposals of the 1959 Act. To all intents and purposes, the Act has wrecked any immediate prospect of the coloured peoples of South Africa being trained to a level permitting them to make the contribution to the development of Africa which they could justly expect to make.

That aspect will undoubtedly deeply influence the attitude of members of the United Nations to the South African Government, and it may well come to affect in due course South Africa's membership of such bodies as the Scientific Council for Africa South of the Sahara, though it must be remembered that the members of that Council are not representatives of Governments or responsible individually to the country from which they are drawn. The Council is rather a body of independent scientists, the primary allegiance of which is to the advancement of science for the benefit of Africa. The Commission for Technical Co-operation in Africa South of the Sahara, on the other hand, is an inter-Governmental organization, and it remains to be seen to what extent it will be possible for the Commission to continue to provide a forum for the discussion of technical matters of importance to the continent while the South African Government maintains its present views on racial questions.

Just what the universities in the Commonwealth can do to offset the weakening of the South African universities by the action of the Government of the country is not easy to say. It is, of course, important that the Commonwealth universities should not confuse the South African universities with the South African Government, and if they can only give moral support, that should be given without stint and at every possible opportunity. The stand which the English-speaking universities of South Africa are making for academic freedom is writing a noble page in the history of the universities of the world. It is important that the academic world as a whole should be fully aware of what is happening in South Africa: of the courage of those who, in spite of sanctions, maintain their disapproval of the new Act; of the ostracism of members of the staff of Afrikaans-speaking universities who defend academic freedom. The withdrawal of South Africa from the Commonwealth has not changed such things, nor has it diminished the claims on the whole academic and scientific world for the support of those who in South Africa are striving so valiantly to maintain the conditions on which scientific advance and academic life depend.

ANALYSIS OF AGRICULTURAL MATERIALS, FOODS AND DRUGS

Official Methods of Analysis of the Association of Official Agricultural Chemists

Edited by William Horwitz. Ninth edition. Pp. xx+832. (Washington, D.C.: Association of Official Agricultural Chemists, 1960.) 18 dollars.

THE Association of Official Agricultural Chemists was founded at Philadelphia, U.S.A., in 1884 by a group of chemists interested in the analysis of fertilizers and their application to growing crops. The earlier work of the Association was concerned with devising methods of analysis for fertilizers and other agricultural materials the composition of which was the subject of State laws; results obtained by these methods were accepted for enforcement purposes. Later, as further legislation controlling food, drugs, insecticides and fungicides was introduced, the interests of the Association widened to include these items. Eventually, in 1920, the methods were published in book form under the title *Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists*, and, by that time, the range of contents had become extensive, covering beverages, foods and related substances, in addition to agricultural materials and drugs.

Methods are continually being tested by the Association in order to keep pace with new legislation, and the established methods are constantly reviewed in the light of developments in analytical technique. Any changes or additional methods are published first in the Association's journal, and are eventually incorporated into the book of methods, which is revised every five years for this purpose. The present, ninth, edition therefore represents the accumulated work of 76 years.

Except for the omission of the words "and Tentative", the title of the book has remained the same during these nine editions, and, to those readers who are not familiar with the work of the Association, it could be misleading, as it suggests that agricultural analyses form the main subject. The table of contents shows this is not so: of the 43 chapters, only seven are directly concerned with agriculture. Indeed, the chapter on soils which was included in previous editions has now been omitted because of the specialized nature of that subject. In effect, the operative word in the title is "Official", and it is to analysts who are concerned with the examination of foods, beverages (both alcoholic and non-alcoholic), drugs, fertilizers and feeding stuffs that this book must prove most useful. As a source of standard methods it holds a unique position, and it is widely quoted for this purpose.

The changes occurring in the new edition are extensive. Classical methods tend to remain unaltered, although a colorimetric method for phosphorus is now included in the chapter on fertilizers, and a useful addition to the Kjeldahl method for determination of nitrogen is a means of standardizing the digestion heaters.

The work of the Association, however, is naturally directed more to modern problems; the danger to public health of pesticide residues on foods, for example, has emphasized the need for methods of determining trace amounts of these newer organic materials. The ninth edition includes methods applicable to certain crops for the extraction and determination of many such pesticides, including aramite, BHC, captan DDT, malathion, methoxychlor, parathion, piperonyl butoxide, sulphenone and thiram.

Also in connexion with the presence of trace amounts are the methods for determining drugs and antibiotics in feeding stuffs. This subject has been extended considerably and now occupies a separate chapter. The chapter covering drugs in general contains many new methods and numerous revisions.

In developing the newer methods, the technique of chromatography on columns is used extensively for the isolation of the desired compounds; the use of paper chromatography is also made official for the first time in this edition, for example, for detecting commercial glucose in honey, other plant materials in vanilla extract and for the differentiation of the BHC isomers.

The examination of foods for "extraneous materials" has been of interest to the Association for many years, and the chapter on this subject, although little different from that in the previous edition, is particularly valuable. Many changes have been made in the section entitled "Nutritional Adjuncts", which now includes methods for the determination of vitamin A in margarine and in mixed feeds, and for the fluorometric determination of vitamin B_1 in bread. The individual methods for the microbiological determination of the B-group vitamins have been replaced by a single general method with appropriate modifications for particular vitamins. A method for the biological evaluation of protein quality is also included in this section.

The actual amount of material in this book is continually increasing, and in order, therefore, to keep the size within reasonable bounds the style of this new edition has been changed to a larger page divided into two columns. The new format is easier to read, and I welcome the change, especially as it means that further abbreviations of the text have thus been avoided. H. V. HART

CONTROLLED THERMONUCLEAR REACTIONS

Plasma Physics and Thermonuclear Research

Vol. 1. Edited by G. Longmire, James L. Tuck and W. B. Thompson. (Progress in Nuclear Energy, Series XI.) Pp. vii+612+xii. (London and New York: Pergamon Press, 1959.) 105*s*. net; 15 dollars.

Nuclear Fusion

Edited by Prof. William P. Allis (Second Geneva Series on the Peaceful Uses of Atomic Energy.) Pp. viii+488. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1960.) 12.50 dollars; 94*s*.

Controlled Thermonuclear Reactions

An Introduction to Theory and Experiment. By Samuel Glasstone and Ralph H. Lovberg. Prepared under the auspices of the Office of Technical Information, United States Atomic Energy Commission. Pp. xvi+523. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1960.) 5.60 dollars; 42*s*.

THE opening in September 1958 of the second International Conference on the Peaceful Uses of Atomic Energy will go down in scientific history as the day the dam burst. It was then that the veil of secrecy was removed from some six years of intensive study in the United States, the United Kingdom and the U.S.S.R. of what is now generally called nuclear fusion. The views and results of hundreds of scientific workers were suddenly thrown open for free discussion, and were supplemented by an exhibition of working experimental equipment on an unprecedented scale.

The first of these three books provides the edited proceedings of this part of the Second Geneva Conference. It is divided into surveys of progress in the chief countries working in this field, followed by reviews of the main experimental devices, the *Stellarator*, the magnetic mirror, the plane shock and the pinched discharge.

These are succeeded by a series of more general theoretical papers on plasma physics and finally by proposals from the U.S.S.R. and the United States for more esoteric methods of stabilizing hot plasma, such as the *Astron*.

Valuable though this collection is, the papers are not easy reading; hence the second book, by Prof. Allis, which is successful in providing most of the information in a more easily digested form, is welcome.

The third work, by Glasstone and Lovberg, carries the process of digestion still further, and is an excellent advanced introduction to the whole subject. It is a graduate text-book carefully thought out to meet the needs of experimentalists rather than of theoreticians, though theoreticians will find it a valuable guide through the thicket of experimental results and devices. Particularly good is the second chapter. Here are discussed the physical conditions which have to be met for thermonuclear reactions to occur at all, as well as those needed to achieve a net gain of power in any practical device.

It is now clear that the difficulties in the way of the attainment of economic power by fusion of the isotopes of hydrogen are formidable. The fuel (deuterium gas or a deuterium–tritium mixture) must be confined in a space isolated from material walls and maintained in the ionized state at an extremely high temperature (some tens or hundreds of millions of degrees) for recurrent periods each lasting about a second. In nearly all proposals this confinement involves the use of powerful magnetic fields and in the forms most worked with—the simple pinch and the *Stellarator*—they have so far been found to fail because the confined plasmas are basically unstable. Instabilities may take several forms; to discover means of curbing them calls for a much deeper understanding of their nature than exists at present, and of the way they build up from small perturbations to large disturbances and so cause the plasma to escape.

The authors deal in as clear a way as seems possible to-day with this matter, as well as with radiation losses from a very hot plasma, including 'cyclotron' radiation-loss at high temperatures, a spectre raised by Russian workers two years ago and not yet fully laid.

In his foreword to the book, Dr. A. E. Ruark expresses the hope that it will command the respect and gratitude of a world-wide audience. He can be assured that it will.

These three works show that the achievement of economical controlled thermonuclear power presents an exceptional scientific and technical challenge, one so difficult that it may indeed never be possible to meet. It is far too early to be pessimistic about the outcome of this great enterprise, but it is now clear that success will not be easily attained nor will progress be so rapid as with power from nuclear fission. BASIL SCHONLAND

CARBOHYDRATE CHEMISTRY

The Carbohydrates

By S. F. Dyke. (The Chemistry of Natural Products, Vol. 5.) Pp. v + 232. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1960.) 36*s*.

THIS book is one of a series of monographs designed to supplement the general text-book of organic chemistry with more detailed descriptions of the main groups of natural products. It gives a balanced account of the various facets of carbohydrate chemistry, and the text is adequately supplied with references to reviews and original papers. The author assumes little or no previous knowledge of the subject, but the treatment is sometimes sketchy and some of the material is presented in the form of notes with little commentary. One feels that the student would have been better served if the evidence for recent developments in the field had been treated more fully, and if greater emphasis had been given to the present growing points of the subject. In these respects this volume does not reach the high standard set by some earlier volumes in the series.

The first three chapters of the book deal with the basic chemistry of the monosaccharides, their general reactions, stereochemistry, and ring structures. In the two following chapters, derivatives of monosaccharides are discussed, both those used in synthesis and structural studies, and those of natural occurrence, including the branched-chain sugars and deoxy sugars. It is a pity that, apart from two rare sugars found in antibiotics, sugars containing more than six carbon atoms are not discussed, and that no mention is made of the aldoheptoses found as constituents of polysaccharides from micro-organisms, or of the naturally occurring heptuloses and heptitols, or of the sialic acids with nine carbon atoms. The next chapter provides examples of *O*-glycosides of plant origin, but no space is found for any discussion of the chemistry of *N*-glycosides, for example nucleotides. The chapter on oligosaccharides gives examples of both chemical synthesis of disaccharides and of the determination of structure of di- and tri-saccharides. There follows a brief survey of polysaccharide chemistry, including an account of general methods of structural determination and a description of some representative groups. Although the full potential of enzymes as tools for structural investigation of polysaccharides has yet to be realized, one feels that their use in the elucidation of the fine structure of starch and related polysaccharides deserves more specific mention. The book is concluded with a chapter on carbohydrate metabolism with sections on glycolysis, photosynthesis, and the biosynthesis of monosaccharides and polysaccharides.

At present-day prices the book is reasonable value. There are comparatively few errors, and the general standard of production is good.

G. O. Aspinall

HUMAN NUTRITION

Recent Advances in Human Nutrition, with Special Reference to Clinical Medicine

By Prof. J. F. Brock. Pp. xii+454. (London: J. and A. Churchill, Ltd. 1961.) 50*s*. net.

PROF. BROCK has contributed considerably to our knowledge of human nutrition by a large amount of important research. Reluctantly, one must conclude that he has not contributed anything like so impressive a book.

To begin with, it is impossible to decide the sort of person for whom it was written. Certainly not for the average clinician, for he would have no idea of what is meant by "*cis-trans isomerism*". The nutritionist, on the other hand, would not accept that "there is no specific sign of riboflavin deficiency in the human". Moreover, the nutritionist would have to be very magnanimous to forgive the misspelling of one of the world's outstanding nutritionists as "Bam".

The first eighteen chapters of the book are written by Prof. Brock himself. The remainder is written by a number of other nutritionists, and, as is so common with multiple authorship, the result is uneven. Indeed, it is difficult to understand why some parts were included at all, since they have little or no bearing on nutrition. An interesting feature is that several chapters describe the nutritional work in particular areas; much of this information will be new even to many nutritionists.

It is understandable that Prof. Brock and his colleague Dr. Bronte-Stewart, who have done a great deal of original and important work on the subject, should stress the possible role of dietary fat in the causation of coronary disease. But in a book of this sort one would have liked to see rather more mention of the contradictory evidence in the alleged connexion between the two. Many would not agree, for example, that "only the dietary fat intake remains consistently in parallel with the mortality experience of this disease".

Again, one is disappointed to find that the myth is still perpetuated that the cause of obesity "remains a mystery". It is just not true that "there is still a fortunate majority who can dispose of excess calories with impunity and an unfortunate minority who have to count every calorie".

There are very few books dealing generally with the subject of nutrition, so that this book, by Prof. J. F. Brock, was eagerly opened and read by me. It is disappointing to have to report that the book does nothing to enhance the reputation of a most distinguished clinical nutritionist.

J. Yudkin

GRASSLAND PHILOSOPHY

The Grass Crop

Its Development, Use, and Maintenance. By Dr. William Davies. Second, revised edition. Pp. xv+363+16 plates. (London: E. and F. N. Spon, Ltd., 1960 45*s*.

THE second edition of William Davies's *The Grass Crop*, which has been brought up to date and somewhat enlarged, is again a welcome addition to the literature of the subject. This is not a textbook in the generally accepted sense nor yet a purely practical guide for farmers, for it is something much more profound and wider in its scope. It is, in fact, a clear exposition of grassland philosophy, and threaded throughout its pages is the philosophy of one who has studied grassland in all its facets and in many parts of the world. This is well illustrated by one sentence: "The world at large must recognize that the soil is its one heritage which it must pass on unspoilt and untrammelled to the generations to come".

How true this is and yet how often forgotten in the mælstrom of technical agricultural development to-day. Throughout the book, however, the author is at pains to emphasize the fertility-building properties of the ley as well as its contribution to reclamation and to solving the livestock feeding problems for milk and meat production which face us to-day. Two new chapters, "Farming Systems" and "Extending the Grazing Season", pin-point the remarkable changes that have occurred in our farming of recent years and outline something of the vast potential which the grass crop still has to offer.

A cautionary word, too, is uttered on the too slavish adoption—a modern trend—of statistical analysis of new techniques before they are advised for incorporation into farm practice. Each farmer should interpret experimental results for himself and try to relate them to his own specific conditions. He should try new methods which, in the light of his experience, offer advantages. The trial may fail, but it is far better to fail on the chance of succeeding than not to try out a new technique simply because in trial plots the results did not attain the desired level of significance to suit the statisticians.

Future prospects are very ably summarized in a final chapter when problems facing both research workers and farmers are clearly stated. The problems cited do not simply concern grass as a crop, but also the animals which consume the grass. Animal nutrition is as important as crop nutrition, and only of recent years has research indicated that there are fundamental differences in herbage plants which dictate the reactions of animals to them in the digestibility and production secured from them when eaten by ruminants. Parasitism raises a multitude of fresh problems which indicates the need for team work between physiologists, veterinarians and agronomists. Then, too, the underground parts of the grass plant are frequently as important, if not more so, than the aerial ones.

Since the first edition of this book appeared in 1952, our knowledge of the grass crop has greatly increased and the full appreciation of its vital role in British agriculture is now more widely acknowledged. The author incorporates throughout the text recent results from experiments at the Grassland Research Institute for Great Britain as well as from elsewhere.

All students of agriculture at all levels should make a point of not only reading this book carefully, but also of studying it seriously. An excellent bibliography and a serviceable index add greatly to its value for students. It has in my view, however, a wider value, and biologists, geographers, geologists and indeed all interested in the countryside will find profit and fascination in its pages.

IAN MOORE

CRYSTAL GAZING

Computing Methods and the Phase Problem in X-ray Crystal Analysis

Report of a Conference held at Glasgow, August, 1960. Edited by Ray Pepinsky, J. M. Robertson, and J. C. Speakman. (International Tracts in Computer Science and Technology and their Application, Vol. 4). Pp. viii+326. (London and New York: Pergamon Press, 1961.) 63*s*. net.

Crystal-structure Analysis

By Prof. Martin J. Buerger. Pp. xvii+668. (New York: John Wiley and Sons, Inc.; London: John Wiley and Sons, Ltd., 1960.) 18.50 dollars; 148*s*.

About a decade ago there was held at Pennsylvania State College a conference on "Computing Methods and the Phase Problem in X-ray Crystal Analysis". The main purpose of this meeting was to exhibit the new X-*RAC* computer designed by Ray Pepinsky, and the volume which described the conference and the machine is one of the important landmarks in the literature of the subject.

Of the machine itself little need be said except that it forms the most powerful tool for Fourier synthesis which has so far been produced. The other papers in the earlier volume were chiefly concerned with the central problem of X-ray analysis, the determination of phase.

In the new book under review, we see how the hopes and aspirations of the workers have developed. The X-*RAC* is still the most powerful machine for its special purpose, but, as Pepinsky points out, it is "an anomaly among computers", an analogue machine which is more economical and capable of greater accuracy for its special purposes than any digital machine yet on the market. Nevertheless, the machine will become of less importance in the future because of the development of new techniques and of the essentially versatile nature of digital machines.

The main portion of the book is, however, concerned with two aspects of modern structure analysis: digital computation and phase determination. Of the former it may be said that all the principal machines and programmes are described. The papers vary from the mere catalogue of programmes for an *IBM* '650', provided by Jeffrey and Shiono, to the extensive description of *Pegasus* and its programmes given by Cruikshank. To say that these papers were dull would be unfair, but they are unlikely to be of great interest to anyone who does not have access to one of the machines described. An exception should perhaps be made in favour of Robertson's paper, which describes a charming little machine having the code-name *Rufus*, an indication that in these days of high-speed electronics there is still place for mechanical ingenuity.

The papers which deal with phase determination and theoretical crystallography are revealing. They range from the extremely useful analysis of least-squares techniques by Sparks, to the disappointingly short paper on the later history of direct methods of phase determination by Hauptman. Experimental methods of phase determination also receive attention and the phase part of the book may be summed up by the statement that, with complex structures at least, if no experimental method of phase determination is available the theoretical methods are unlikely to be of much help.

The book is well produced, and authors, editors and publishers alike must be congratulated on producing it so soon after the conference. It will be an essential book for all serious crystallographers.

Buerger's book, while dealing with many of the topics covered by the specialists in the previous work, is a systematic study of the whole process of crystal structure analysis. It starts with a description of the fundamental processing of X-ray diffraction, explains the experimental techniques which are used to obtain X-ray data, and then derives the various expressions which are needed to reduce these data to a form suitable for Fourier analysis.

The latter part of the book is a compendium of Fourier methods, from practical procedures of computation to theoretical techniques of phase determination. Although the book contains nearly 700 pages the whole subject of vector space is barely mentioned—it is the subject of an earlier book by Buerger—and one gets the impression of increasing compression of treatment towards the end. This terseness is, however, relieved by the excellent lists of references which end each chapter, and, were it not for the extremely high price, every student of crystallography would find the book an essential part of his library.

A. D. BOOTH

Tin and Its Alloys

Edited by Dr. Ernest S. Hedges, with the collaboration of Prof. J. W. Cuthbertson, Prof. E. C. Ellwood, Dr. W. E. Hoare and W. R. Lewis. Pp. viii+424. (London: Edward Arnold (Publishers), Ltd., 1960.) 126*s.* net.

THIS book of more than four hundred pages is more in the nature of an encyclopædia than a text-book, and no significant aspect of tin and its uses is overlooked. Prepared by experts in the different aspects of the subject, all of whom are, or have been, connected with the Tin Research Institute, the treatment is authoritative. Despite the wide scope of the ground covered, there is nothing superficial in the discussions, and the 187 figures are well reproduced and pertinent.

After an introduction by Dr. E. S. Hedges, tin in its cast and wrought forms is dealt with, and it will come as a surprise to many to learn that several tons of the metal are to be seen in the enormous pipes in the organ at the Albert Hall in London. Two chapters are concerned with the physical metallurgy and chemical behaviour of tin and its alloys. The approach, however, is really to the user of the metal, and the treatment of the scientific aspects is subordinate to the more directly practical. It is, however, adequate both for the purposes of the manufacturer and for the engineer, chemical or otherwise, who uses the product. Where so much is good, it is almost invidious to single out Prof. Cuthbertson's account of the metallography of the bronzes for special mention.

The electrodeposition of tin and its alloys, hot-tinning, tin-plate, tin in bearing alloys, die-casting alloys, solders and bronzes are all treated at sufficient length to be really informative. The extent of the treatment is vast, and readers interested in the tomb of the Empress Maria Theresa, in the tinning of cast iron or in Babbitt's original patent of 1839 will all find what they seek.

Within the obvious limitations of the space available, it is difficult to see how this publication could have been bettered. F. C. THOMPSON

The Moon

Our Nearest Celestial Neighbour. By Prof. Zdeněk Kopal. Pp. vii+131+15 plates. (London: Chapman and Hall, Ltd., 1960.) 25*s.* net.

FOR many years the Moon was neglected by all except a few enthusiastic amateur observers. The recent developments in space research have led to a welcome change of attitude, and professional astronomers also have begun to pay attention to lunar studies. The latest book on the subject, by Prof. Z. Kopal of the University of Manchester, is written at an elementary level, and may be followed throughout by the layman; its greatest appeal will probably be to younger readers. It is attractively produced, and the photographs, many of which have been taken at the Pic du Midi Observatory, are excellent.

Beginning with fundamental facts, the author goes on to describe what he calls "the Strange World of the Moon", and considers the various theories of crater formation. On this controversial subject he is wisely cautious, and believes that both vulcanism and meteoric impact may have played a part in the moulding of the surface. The actual nature of the surface is further discussed in the next two chapters, after which a section is devoted to the observation of an outbreak inside the crater Alphonsus, reported in 1958 by the Russian astronomer N. A. Kozyrev. The final chapter is entitled "Destination Moon", and is frankly speculative, though the author carefully refrains from any flights of fancy.

A few minor criticisms may be made. In particular, some of the important studies of recent years are not mentioned; a notable omission is any reference to G. Fielder's investigations with regard to the lunar grid system. There are also one or two over-simplifications, and a number of misprints, such as 'air' instead of 'aid' on p. 19. The general impression is, however, of a very pleasant and readable little book. PATRICK MOORE

Practical Organic Chemistry

By Dr. Frederick George Mann and Dr. Bernard Charles Saunders. Fourth edition. Pp. xix+585. (London: Longmans, Green and Co., Ltd., 1960.) 25*s.* net.

FOUR editions within twenty-five years testify to the success of this book in a highly competitive market. They also mark the authors' concessions to the claims of evolving techniques. In this latest edition increased emphasis is given to semi-micro methods, both of preparing and characterizing organic compounds; there is a section—all too brief—on chromatography, including the use of ion-exchange resins; the scope of qualitative analysis is enlarged over that of previous editions; and the variety of standard syntheses is increased by new examples. Spectroscopy is not included, and perhaps this is wise although, even in organic teaching laboratories, automatically recorded spectra are now increasingly invoked. Certainly, in spite of judicious pruning, the new edition is larger by more than a hundred pages and further increase must bring into question the advisibility of combining within a single volume both elementary and more advanced techniques. Meanwhile, "Mann and Saunders" maintains the style and character which have given it wide acceptance. J. D. LOUDON

Qualitative Organic Analysis

By B. Haynes. Pp. 239. (London: Cleaver-Hume Press, Ltd., 1961.) 17*s.* 6*d.*

THIS book is designed for students in the range from National Certificate to university-level. It is self-contained in that detailed instructions for each step towards identifying a simple substance or mixture are combined with reference tables of melting points and boiling points for a generous selection of compounds and their useful derivatives. It gives the author's approach to teaching the subject and bears his emphases and preferences. Stress is placed on preliminary tests, chemical formulæ and equations are deliberately omitted, and supplementation by lectures is implied. A good standard of lucid description is maintained throughout, but the order in which classification tests are arranged will not appeal to all tastes, and more generally, one feels that the student may have difficulty in penetrating the mass of detail to the principles underlying the analysis. However, the book is rich in sound, useful information and fully merits consideration by teachers of the subject.

J. D. LOUDON

STRONTIUM-90 IN FALL-OUT AND IN MAN IN AUSTRALIA, JANUARY 1959–JUNE 1960

By Dr. F. J. BRYANT
Atomic Energy Research Establishment, Harwell

L. J. DWYER, D. J. STEVENS, Prof. E. W. TITTERTON, C.M.G.
Australian Atomic Weapons Tests Safety Committee
AND

and J. R. MORONEY
Department of Supply, Melbourne

EARLY in 1956 a network of stations established by the Atomic Weapons Tests Safety Committee commenced to monitor radioactivity in fall-out over Australia from weapon tests at the Monte Bello Islands and at Maralinga, as well as from those held overseas[1–7]. The number of stations operative, as well as the type of sampler employed in this network, has varied from time to time. Many more stations were used during periods of weapon tests in Australia, and the sensitivity of monitoring techniques has been improved as fall-out levels decreased. Early in 1957 the monitoring programme as a whole was extended to include the determination of strontium-90 in materials representative of the Australian environment, and this has become a major feature of the programme. The results from this strontium-90 survey to the end of 1958 have already been reported[8], and since that time the number of samples collected has been increased considerably. Thus, 744 specimens of total precipitation, soil, powdered milk, cabbages, wheat grain, and sheep and human bones were collected during 1959, and 1,230 during 1960. In order to avoid unnecessary analyses, specimens of the same type were sometimes combined together to provide a single representative sample, and as a result a total of 480 analyses are involved. The analytical effort is being provided by the following laboratories: (1) Human bone; by the Woolwich Outstation of the Atomic Energy Research Establishment, Harwell (under the direction of one of us—F. J. B.), and the Lamont Group at Columbia University; (2) precipitation samples: by the Health and Safety Laboratory of the U.S. Atomic Energy Commission, as part of a world-wide 'high wall pot' programme; (3) wheat grain: by the U.K. Agricultural Research Council Radiobiological Laboratory; (4) all other material : by the Woolwich Outstation of the Atomic Energy Research Establishment, Harwell.

Although analysis of all samples for the period is not yet complete, extensive data for human bone, from Woolwich, and for precipitation, from the Health and Safety Laboratory, are to hand for the 18-month period January 1959–June 1960. Because of their importance and interest, they are reported in this article. Later this year the bone data from Lamont will be published with all other data.

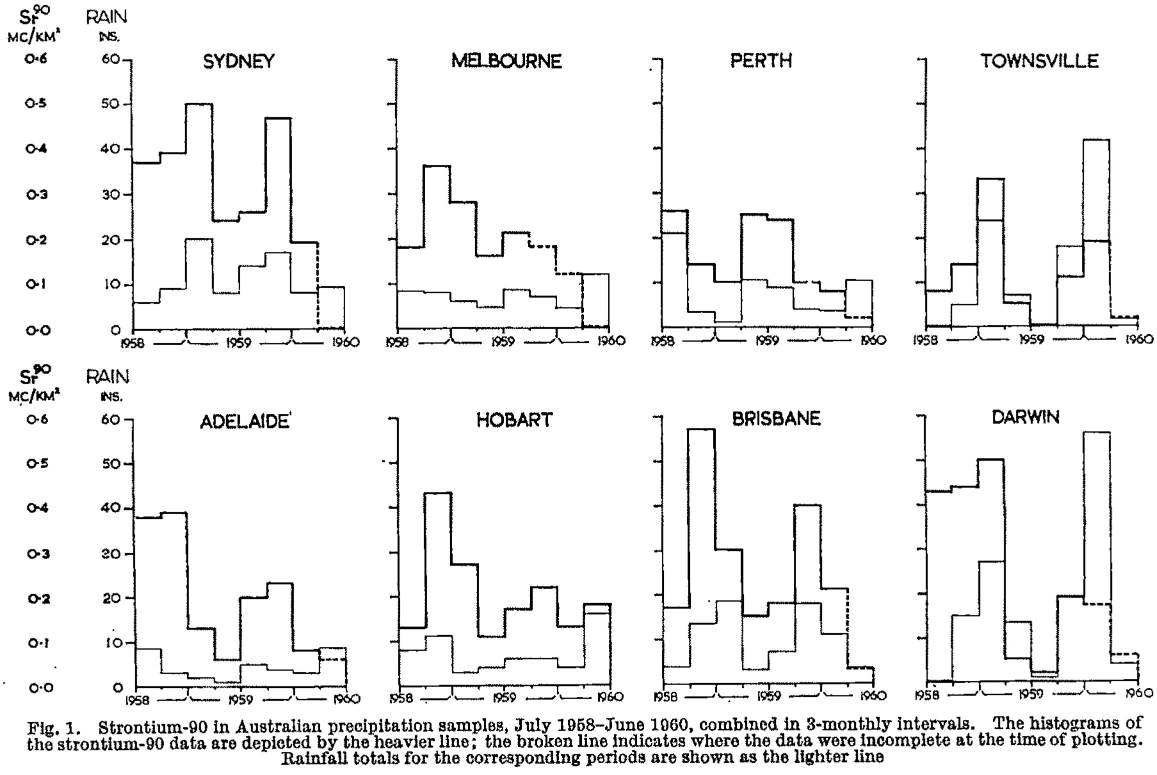

Fig. 1. Strontium-90 in Australian precipitation samples, July 1958–June 1960, combined in 3-monthly intervals. The histograms of the strontium-90 data are depicted by the heavier line; the broken line indicates where the data were incomplete at the time of plotting. Rainfall totals for the corresponding periods are shown as the lighter line

Table 1. (*a*) STRONTIUM-90 IN AUSTRALIAN HUMAN BONE, 0–59 MONTHS, JANUARY 1959–JUNE 1960
The age of each specimen contributing to a sample is given; where there is more than one specimen of a particular age, the number is shown in brackets. An asterisk indicates that no specimens were available in the age-group, although in some cases †, because the available specimen mass was insufficient for analysis, the specimens were combined with adjacent age-groups

Sampling Methods and Results

(*a*) *Human bone tissue.* Between January 1, 1959, and June 30, 1960, 890 specimens of human bone tissue were collected through the agency of pathologists in the five capital cities—Perth, Adelaide, Melbourne, Sydney and Brisbane. Each of these specimens was ashed at 800° C. and then weighed. The ashed specimens were divided into three groups corresponding to the periods: January 1–June 30, July 1–December 31, 1959, and January 1–June 30, 1960. For each of the five capital cities specimens collected during these periods were divided into five age-groups: less than one month, 1–23 months, 24–59 months, 5 years–19 years and 20 years and older. In a few cases there were gaps due to specimens for the relevant period and age-groups being unavailable. Within each age-group an equal mass of ash was taken from individual specimens, and these equal masses were combined to form the sample for analysis. The resulting 59 samples were analysed by the Woolwich group.

The reported, near-uniform distribution of strontium-90 through skeletons of age up to 20 years[9,10] allowed samples representative of the four age-groups to be prepared by mixing different bone types from the appropriate collection periods. However, in view of the known non-uniformity of strontium-90 concentration in the adult skeleton, the survey of adult tissue was restricted to a single bone type for each capital city.

The results are presented in Tables 1*a*, *b* and *c*; the age of each infant specimen is included in Table 1*a*.

(*b*) *Total precipitation.* Stainless-steel high-walled pots, 12 in. diameter and 12 in. high, were continued in operation at the eight stations: Perth, Adelaide, Melbourne, Hobart, Sydney, Brisbane, Townsville and Darwin. The monthly collections from these pots were analysed at the Health and Safety Laboratory[11]. The analytical results from July 1958 until June 1960 have been accumulated in 3-monthly intervals and plotted as histograms in Fig. 1. Rainfall data have been arrayed in a corresponding manner.

Discussion

Fig. 1 indicates an overall increase in strontium-90 fall-out over Australia in late 1958 and early 1959. During 1959 the level decreased markedly before increasing somewhat in most localities towards the end of the year. The relatively short period covered by the data in Fig. 1 precludes a constructive analysis of any relationship between fall-out and precipitation in Australia. Further seasonal variations in deposi-

tion of strontium-90 are to be expected in the future, and an analysis of these may be profitable at a later stage if there is no further large-scale injection of strontium-90 into the atmosphere. For purposes of comparison, Table 2 presents the data combined in 6-monthly periods, together with results from measurements in the United Kingdom[12,13] and the United States[11]. The British station is that at Milford Haven, where measurements have been made since 1954, and for which the most detailed data exist. The American station at Los Angeles is selected as being representative of the west coast of the United States, where fall-out levels are, in general, low; the region of higher fall-out, on the east coast, is represented by New York.

The deposition of strontium-90 in Australia in the period July 1958–June 1959 ranged from 0·6 to 1·5 mc./km.^{2}, with a mean value for the eight stations of 1·0 mc./km.^{2}. The 1·0 mc./km.^{2} is one-third of the deposition at Los Angeles, one-tenth of that at New York and one-seventh of that at Milford Haven, in the corresponding period. The results for Australia do not show the marked rise in deposition of strontium-90 evident in the northern hemisphere during the period January–June 1959, which was mainly due to weapon tests during October–November, 1958.

The strontium-90 content of bone tissue is known to vary between individuals of a single age-group and from one group to another. Some difference between the results for the capital cities in individual age-groups is therefore to be expected, particularly when the number of specimens in the sample is small. The observed differences are not systematic throughout all age-groups, and the results in each age-group have been combined to give weighted mean values for Australia. These are shown in Table 3, which also includes the results of measurements on bone tissue in the United Kingdom[14–18] for comparison.

For all age-groups the mean level of strontium-90 in Australian human bone increased during 1958–59; but for younger tissue this rise was not carried into 1960. For the 0–1 month and 1–23 month age-groups, the increase was about two-fold; but it was followed by a downward trend into 1960. The level in the 24–59 month age-group rose later in 1959. The 5–19-year and over 20-year age-groups showed a slow rise over this period, which is to be expected with the turnover of pre-existing bone and, in the case of children and adolescents, the accretion of new bone tissue.

A similar, approximately two-fold rise in the strontium-90 level of infant human bone tissue also occurred in the United Kingdom in the period 1958–59. In general the levels of strontium-90 in Australian human bone are one-half to one-third of those in the United Kingdom[14–18]. Data for the United States, published by the Lamont Group[19], indicate levels 2–3 times higher than those in Australia.

Conclusions

(1) Mean levels of deposition of strontium-90 in Australia were about one-fourth of those in the United Kingdom and eastern United States during the period July–December, in both 1958 and 1959. The marked increase in fall-out rate in the northern hemisphere during the first half of 1959 was not experienced in Australia. It is probable that the mean annual deposition of 1·0 mc./km.^{2} recorded in Australia for the 12-month period July 1958–June 1959, will not be exceeded.

(2) The measurements on Australian infant bone tissue indicate that the level of strontium-90 in newly formed bone passed through a maximum during the period January–June 1959, and showed a downward trend to mid-1960. As expected, the levels in child, adolescent and adult bone tissue continued to increase gradually. At all ages the levels in Australian human bone tissue are one-half to one-third those in the United Kingdom and the United States.

(3) The Medical Research Council in Britain recently[20] accepted a recommendation of the International Commission on Radiological Protection that the maximum permissible level of strontium-90 in bone, averaged over the whole population, should be 67 μμc./gm. calcium, and for any individual in the population, 200 μμc./gm. calcium. At the same time, the Council revised its previous cautionary level at which a re-assessment of the situation would be required, from 10 to 33 μμc. strontium-90/gm. calcium. It will be seen that the levels found for

L. EULER, THE PRINCIPLE OF RELATIVITY AND THE FUNDAMENTALS OF CLASSICAL MECHANICS*

By D. SPEISER

Institute for Advanced Study, Princeton

SINCE they received their definite form through Newton, the significance of the fundamentals of classical mechanics has always remained a controversial subject, at least up to 1905. Where Newton had spoken of absolute space and time, and referred to experiments, some of his successors pretended that they did not need such hypotheses, or even went so far as to reduce his famous second axiom to a mere definition. Thus the boundary between mathematics and physics as an experimental science was strongly displaced at the expense of the latter, from which the so-called pure mechanics was separated.

Others, on the contrary, insisted on the basically experimental character of this axiom. There have been many attempts to display the long series of arguments from all sides of this very involved discussion. It is the aim of this article to direct attention to a single point of this process, namely, the instant where probably for the first time there emerged a completely new point of view: the confrontation of mechanics with optics. It will be shown that the result of this confrontation was the recognition that the principle of relativity, closely connected with the fundamentals of mechanics, was called in question. It is therefore appropriate to dedicate this article to the memory of Wolfgang Pauli who, forty years ago, in December 1920, published his famous article on relativity theory in the *Mathematical Encyclopedia*.

The discovery that the principles of classical mechanics are entangled with the principles of optics was made by Euler in 1739. Or, as we can put it more precisely, he discovered that the decision between a wave and a corpuscular theory of light reflects on the validity of the principle of relativity. (Already in his *Mechanica*, published three years earlier, he had devoted the first chapter to an ample explanation of the difference between relative and absolute motion, cf. "Mechanica sive motus scientia analytice exposita", *L. Euleri Opera Omnia*, Ser. Sec. 1, 13.) In a paper of that year, he examines the aberration, discovered by Bradley in 1727, mainly in order to calculate corrections for astronomical use. The aberration is a systematic error in observing the stars, of the magnitude of 20″, which occurs through the Earth's movement in relation to the stars. Presuming that the fixed stars stay at rest, then three movements remain, of which the influence on the observation may be calculated: the daily rotation of the Earth, the yearly rotation of the Earth, and the movement of the planets. But, it is characteristic of Euler that he is not only interested in the special problem to which this examination gives rise, namely, the calculation of the required correction, but he rather attacks the question in its fullest generality as a physical problem. The astronomical calculation is only the starting point for investigating basic questions in mechanics, where the astronomical language is a mere fashion of presentation. Euler distinguishes four cases, which he examines one after the other: (1) the observer and the object are at rest; (2) the object moves; (3) the observer moves; (4) object and observer move.

For the second case he then derives the aberration formula. In the course of this, he notes that one may ask whether the velocity of light depends on the velocity of the radiant object (always measured in the rest system of the observer). But he himself gives the answer that this is not the case, since the propagation of light is a wave process in the stationary ether, which is independent of the movement of the emitting body, and he finds for the correction (I use Euler's notation):

$$\mathrm{tg}\alpha = \frac{ms}{c - \mu s}$$

where α is the angle between the observed and the true location of the object, c and s are the velocities of light and the object respectively, m and μ sine and cosine respectively of the angle between the light ray and the velocity of the object. He applies his formula to the simplest forms of movement (movement on a straight line and on a circle). Thereby he reaches the conclusion: to an observer at rest, the speed of a body in uniform and rectilinear motion seems to diminish more and more with increasing distance.

---

* This article is an enlarged version of a chapter of the author's introduction to the forthcoming volume containing the papers referring to physical optics of *L. Euleri Opera Omnia*. Euler's article, "Explicatio Phaenomenorum quae a motu lucis successivo oriuntur", was published in the *Commentarii Academiae Scientiarum Imp. Petropolitanae*, Tomus XI ad annum MDCCXXXIX, but appeared only in 1750.

Now the third case, which for practical application is the most important: the object rests and the observer moves. Since Euler was one of the few authors who do allow the reader to participate in his investigations and to watch closely his paths, it might be worth while to report his reasoning in detail. For here it is possible for once to observe singly the steps through which a fundamental discovery is reached and to pinpoint as closely as possible the exact moment at which a crucial insight is gained.

He starts from the remark that one may reduce this case to the previous one by giving the system observer–object a speed which is equal but opposite to the original velocity of the observer. Therefore one may take over the formulæ derived above (that is, those derived in case 2) and apply them also to this case:

$$\operatorname{tg}\alpha = \frac{mr}{c - \mu r}$$

where r is now the velocity of the observer and m, μ are the sine and cosine respectively of the angle between the light ray and the direction of the observer's motion. This formula seems to settle the problem.

Euler, however, is not yet satisfied and wishes, as he says (section 20), "to investigate the effect which the light ray exerts on the eye in motion and the difference between the true and the apparent place according to the rules of motion". This investigation is essentially independent of the former and therefore a new derivation of the correction formula.

The velocity of light in the ether and the velocity of the observer are now added according to the rules of kinematics. Euler explains hereby his short trigonometric calculations amply with the help of his vector diagrams. But now one is surprised to find the astonishing result—the correction computed with this method differs from that found before: one gets:

$$\operatorname{tg}\alpha = \frac{mr}{\sqrt{c^2 - m^2r^2}}$$

instead of:

$$\operatorname{tg}\alpha = \frac{mr}{c - \mu r}$$

Euler asks: From where does this difference arise and which of the two answers, both the result of what appear to be rigorous derivations, is the correct one? First he remarks: it is clear that the difference arises from the fact that in the first derivation because of the reduction to case 2 we had implicitly assumed that the light velocity remains c, independent of the speed of the observer, whereas in the second derivation the light velocity becomes $y = \mu r + \sqrt{c^2 - m^2r^2}$.

The decision between the two correction formulæ therefore is reduced to the question, Which is the correct velocity of light? Euler now observes, the system under consideration comprises not only object and observer, but also the ether, which hence ought also to have received the same speed, which of course is excluded. In other words, the ether distinguishes an absolute system, and cases 2 and 3 are not equivalent but basically different. Equivalence between both cases, however, would hold in a corpuscular theory, as he points out, for in such a theory no ether distinguishes an absolute co-ordinate system and the principle of relativity (Euler says: "haec hypothesis . . . *motus compositionem* recipit", Section 28) prevails. (This is the point of departure for W. Ritz's attempt at corpuscular optics, in order to explain the negative result of the Michelson experiment. Cf. W. Pauli's article in the *Mathematical Encyclopedia.*) Therewith, Euler found what he had looked for; an 'experimentum crucis' which permitted at least in principle a decision between the two theories, wave and corpuscular optics. However, the difference is too small, as he notes explicitly, to be susceptible to experiment—in this case the astronomical measurement. Euler therefore calculates in his further investigations with his simpler formulæ which follow from the corpuscular hypotheses, since they coincide with those of the wave theory to within a difference of the second and higher order in v/c, that is, he makes full use of the principle of relativity (linear addition of the velocities).

This piece of work seems to me to be one of the most beautiful that Euler ever wrote; perhaps one may regard it as one of the classical papers in physics. This is not only because of its clarity and elegance, but also much more so for the peculiar manner in which a seemingly simple question gives rise to a discussion of the most basic principles of physics. At first one believes to have caught Euler with an error and one is then even more surprised by the infallibility with which he aims at the point which more than a hundred years later was to become the centre of discussion about the fundamentals of mechanics. How surprised, on the other hand, he would have been to learn that the decision had been made in favour of the principle of relativity and against the ether, and that this decision was made just on the grounds of the wave optics confirmed meanwhile by the Michelson experiment which is closely related to aberration! This might be another example of what W. Pauli used to call "the life of the ideas", "showing", as he formulates it in the preface to the second edition of his article, "how a fundamental scientific discovery, sometimes even against the resistance of its creator, gives birth to further fruitful developments following its own autonomous course". Though perhaps in this case one rather should say "even in a direction opposite to the intention of its creator. . . ".

From the following remark quoted from Section 35 of his paper, it is clear that Euler was well aware of the significance of the so-called systems of inertia as well as their peculiar problems: "licet enim salvis legibus et regulis *mechanicis* universo cuidam systemati corporum motum aequabilem in directum imprimere, eta, ut nil in phaenomenis mutetur, at vel motum inaequabilem vel curvilineam tribuere minime licet". This demand, namely, to regard the question not only as a kinematical but also as a physical one ("legibus et regulis *mechanicis*" . . .) should have saved him from being decried as having only a rather formal attitude towards physics. In this particular fashion of looking at those problems he remains the "true son of Newton", to quote C. A. Truesdell (cf. the introduction to vol. 8, Ser. Sec. of *L. Euleri Opera Omnia*, p. cxviii). However, just the mathematicians and sometimes even the physicists later on often overlooked this point, whereas Euler thought of the foundations of mechanics as subject to experimental examination. His explanations on how the speed of a moving object appears to an observer at rest are a first tentative prelude to Einstein's later criticism of time measurement.

There is an amusing question to be asked concerning the response to this paper. It was written by Euler in 1739, but its publication by the Academy of St. Petersburg was delayed until 1750. Meanwhile, he had published in 1748 a continuation to it in the *Mémoire de l'Académie des sciences de Berlin* (Mémoire sur l'effet de la propagation successive de la lumière dans l'apparition tant des planètes que des comètes, 1746. The volume was printed, however, in 1748.) There, however, he did not enter into the question: wave or corpuscular optics, but applied without further explanation the simpler formulæ of corpuscular optics as an approximation in the above-mentioned sense. A careful reader could have objected that Euler was in contradiction to the principles of his own wave theory, proposed and discussed in detail in his *Nova Theoria Lucis et Colorum* published in 1746.

Was there such a careful reader ?

I received much encouraging criticism and various stimulating suggestions from Prof. A. Koyré. I am indebted to Dr. G. Barton for his linguistic advice. I wish also to express my gratitude to Prof. J. R. Oppenheimer and the Institute for Advanced Study for the generous hospitality offered to me.

THE BREEDING OF IMPROVED MILKING COWS THROUGH ARTIFICIAL INSEMINATION*

By Dr. J. EDWARDS and Dr. L. K. O'CONNOR
Production Division, Milk Marketing Board, Thames Ditton, Surrey

THE story of commercial artificial insemination in Great Britain is quite a short one, spanning, in fact, less than twenty years, for it was as recently as November 1942 that the first commercial artificial insemination (A.I.) centre was opened at Cambridge. In 1944, the Milk Marketing Board took over its first centre—Beccles—from the North Suffolk Cattle Breeders, and subsequent expansion was so rapid that by December 1958, only some fourteen years after acquiring its first centre, the Board's organization had inseminated a total of 10 million cows[1]. Now the 23 Milk Marketing Board and 6 non-Board centres, which together provide the artificial insemination service in England and Wales, inseminate more than 2 million cows a year, or approximately 60 per cent of the national herd. The Milk Marketing Board centres alone inseminate more than 1½ million cows a year, of which about 1 million are with semen from dairy and dual-purpose bulls.

In addition to the growth in the use of artificial insemination which is still continuing, there have been technical developments in the dilution and storage of semen, so that now one bull may be used for upwards of 10,000 inseminations a year, a figure which seemed impossible a short while ago, and the method is therefore well suited to the exploitation of a superior bull. Further, semen can be stored apparently indefinitely at a temperature of − 79° C.; this facilitates transport and makes possible better utilization of semen.

The aim of the artificial insemination organization of the Milk Marketing Board is to breed cows capable of giving, economically, relatively high yields of milk of satisfactory quality as regards composition. Since in Britain at the present time milk is paid for on the basis of quantity, milk yield is a characteristic of major importance; but the milk produced must satisfy certain minimum standards of composition and therefore the quality must also be taken into account in selection. It is also necessary that the cows should be capable of economic milk production; in other words, their conformation must be such that they are capable of a long trouble-free life in the herd, they must have a satisfactory temperament, be easy to milk and so on. These factors which go to make an economic cow can only be assessed subjectively, so here we will discuss only milk yield and fat percentage, which are recorded in National Milk Records, the official milk-recording scheme in England and Wales.

The production characteristics, milk yield and fat percentage, are only expressed in the female, and, moreover, the heritability of milk yield is low, being of the order of 0·3. In this situation it is clear that the breeding worth of a bull must be assessed by means of a progeny test, even though as a result the generation interval is increased; for although a bull can be used when he is a year old, he is about six years of age before the result of a progeny test can be obtained even in favourable circumstances. A further problem in assessing a bull's genetic merit for milk yield is that as much as 90 per cent or even more of the differences in level of production between herds are due to environmental factors. This means that the average yield of a bull's daughters may be a reflexion of the environment under which they were milked rather than of the breeding worth of the bull. It was to combat this situation that the contemporary comparison method of bull evaluation was introduced[2-4]. This entails a series of comparisons within herd-years between the average first lactation milk yield of the daughters of the bull and the average yield of their contemporary heifers by other bulls, each comparison being weighted according to the number of daughters and contemporaries. The weighted differences from the separate herd-years are then combined to give a single figure for the bull, which is the mean weighted difference between the first lactation yields of the daughters of the bull and their contemporaries. The total weight on which it is based is a measure of the accuracy of the test. The accuracy of a contemporary comparison can, in fact, be expressed in terms of the total weight (W) and the heritability of single records (h^2) as $\frac{W}{W + (4 - h^2)/h^2}$, which reduces to $\frac{W}{W + 12\cdot33}$ when a heritability of 0·3 is assumed[5]. This fraction may vary from zero for no information to 1 for complete information about the bull's breeding worth, and it increases as W increases.

---

* Substance of a paper read at the 135th meeting of the Genetical Society on March 23.

The weighting is not, however, the only factor to be taken into account in assessing a bull for milk yield. The general applicability of a contemporary comparison rests on the assumption that the contemporary heifers are genetically average for their generation. This may reasonably be assumed to be the case where a bull has been used in artificial insemination and his daughters are consequently scattered through a large number of herds where the contemporary heifers are by many bulls; and it has been found that in these circumstances the contemporary comparison behaves in practice more or less as would be expected in theory. A natural service bull, however, usually has most of his daughters in a single herd, where the contemporary heifers are likely to be by very few, perhaps even by only one, sire. Although the resulting contemporary comparison may not be generally applicable, the method is not useless in such a situation. Indeed, it probably has its greatest value when the daughters of a bull milk mainly in one herd, since it is in these conditions that the environment is likely to have its greatest effect on the average production of a bull's daughters.

In the case of fat percentage, the situation is simpler. The heritability is higher than for milk yield, being about 0·5 as compared with that for milk yield of 0·3; more important, however, is the fact that environmental differences between herds do not affect fat percentage to the same extent as they affect milk yield, so that the average fat percentage of a bull's daughters may be used to assess his breeding merit for this characteristic. The accuracy of a progeny test for fat percentage is $n/(n + 7)$, where n is the number of daughters of the bull. Therefore, 7 daughters will give a progeny test for fat percentage with an accuracy of 0·5, whereas a weighting of 12·33 or approximately 18 daughters are required to give a progeny test for milk yield of the same accuracy.

A bull in artificial insemination can generally be tested through his progeny more accurately than a bull in natural service, both by virtue of his having a greater number of daughters and because these daughters are scattered through a large number of herds. He will also generally be younger when his progeny test assessment is first available. In order to make the best use of the superior bulls which are found, they must be used not only to breed females but also to breed bulls to enter the artificial insemination stud for progeny testing in their turn. In other words, the artificial insemination population must be genetically closed, at least to some extent. The Milk Marketing Board has for some time been using its best bulls to breed sons out of cows with at least four lactations which have proved to have outstanding individual performances in their own herds and which have been approved for conformation, temperament, etc., by a panel of breeders. It has been shown[6] that a large number of young bulls bred in this way will on average be of greater genetic merit than the population as a whole, and by progeny testing it is possible to select the best from this superior group. However, such selection within a closed population is inevitably accompanied by inbreeding, and the question arises of how far one can go in closing an artificial insemination population or in limiting its size.

In practice, because of the long generation interval, the problem is not pressing ; but nevertheless it is one which merits early consideration, and in order to obtain a consensus of opinion, the proposition that "2 million dairy cattle may be bred annually to 200 sires of known breeding merit without genetic deterioration" was put to a number of geneticists, both in Britain and overseas[7]. Their replies were generally favourable.

In considering the problem, two facts must be borne in mind. First, that the artificial insemination population is divided into a number of breeds (the Milk Marketing Board gives service from nine dairy and dual-purpose breeds) varying in importance from Friesians, where about 735,000 cows a year are inseminated, to Northern Dairy Shorthorns, where just over 1,000 cows a year are inseminated. Secondly, milk records are kept for only a minor proportion of cows bred by artificial insemination; the proportion varies with breed and area of Britain, but averages between 15 and 20 per cent, which reduces substantially the effective size of the female population. The consequences of inbreeding in dairy cattle are a reduction in yield, viability and fertility, and Robertson[8] has estimated that there is a fall of 0·32 per cent of the original yield for every 1 per cent increase in the inbreeding coefficient. A small degree of inbreeding is therefore unlikely to have serious consequences, but steps must be taken to ensure that the coefficient of inbreeding does not rise to too high a level. There are three main ways in which this can be done:

(1) A degree of diversity can be maintained by limiting the number of sons by any one bull. This would certainly result in a low rate of inbreeding, but it would also limit the amount of selection which could be applied, and is therefore not a very attractive proposition.

(2) Alternatively, bulls could be introduced from outside the system from time to time but not used extensively until their breeding worth was known. The Milk Marketing Board has been doing this since the inception of its artificial insemination service and will certainly continue to do so for a variety of reasons. However, if, as it should, the average genetic merit of the artificial insemination population rises more quickly than that of the natural service herds, it will become increasingly difficult to find superior bulls from outside the artificial insemination group.

(3) A third possibility is to divide the population into several isolated or semi-isolated groups, so that strains within the breed are formed. This system certainly has a number of genetic advantages, one being that although the different sections of the artificial insemination population would be moving towards the same goal, they would not necessarily be travelling by the same route, so that a degree of genetic diversity would be maintained.

Again, because of the long generation interval in cattle, the exhaustion of genetic variability as a result of continued inbreeding is a secondary problem; but it is possible to safeguard against it by maintaining supplies of frozen semen, so that if necessary some of the genetic variation which has been lost can be re-introduced. In doing so, however, some of the superiority in economic characteristics built up by selection would be lost.

Another danger of inbreeding is that of increasing the frequency of undesirable recessive genes in the population. A bull may be tested for simple recessives either by mating him to 23 of his own daughters, when there is a 95 per cent chance of detecting the 'carrier' bull, or by checking on any abnormal calves resulting from approximately 600 outbred matings when, provided that the frequency of the recessive gene in the population is 1 per cent, there is again a 95 per cent chance of detecting the heterozygous bull.

For the progeny test of young bulls, the Milk Marketing Board carries out 500 inseminations in recorded herds and 500 in non-recorded herds, and these should result in approximately 600 calves being born. Thus if the existing reporting system can be improved, it should be possible to detect the majority of those bulls carrying deleterious recessive genes of importance in the population without resorting to sire–daughter matings. This is the procedure which is favoured. It is true that sire–daughter matings will enable the detection of any recessive gene whatever its frequency, but they are difficult to organize in practice, and therefore it is proposed to carry them out only in exceptional cases.

OBITUARIES

Academician A. F. Joffé

The death on October 14, 1960, of A. F. Joffé, one of the pioneers of physics in the U.S.S.R., member of the Russian and many other Academies, is a severe loss for science. Joffé took a most active part in the remarkable and violent development of physics from the dawn of the twentieth century up to the present time. To the last day of his life he never ceased experimenting with his own hands.

Joffé's early work (1907–13) was devoted to experimental substantiation of the quantum theory set out by Einstein in 1905 while investigating the photoelectric effect and photochemical phenomena. The theory provoked at first adverse comments on the part on many eminent physicists (Ladenburg and others). In 1907 Joffé undertook a theoretical treatment of experimental results obtained by Ladenburg and others, and proved convincingly that Einstein's photon theory was not contrary to, but on the contrary justified by, all experimental data, including those of Ladenburg.

Joffé's experiments on the photoelectric effect exhibited in metal dust suspended in the electric field of a condenser provided direct confirmation for Einstein's theory. Joffé showed that under illumination a dust particle loses its electric charge by portions corresponding to the electron charge, the nature of the process being statistical and in keeping with that of the photon theory. The same experiments supported the atomistic theory of electricity. The conditions of Joffé's experiments were somewhat similar to those of R. A. Millikan, who followed the behaviour of oil droplets suspended in an electric field and showed that all fluctuations in droplet charges were multiple integers of the elementary electric charge. The experiments of Millikan and Joffé were conducted simultaneously and independently, and were published in 1911 (Millikan) and 1912 (Joffé).

In 1913 Joffé published his results on the magnetic field of the cathode beam. The occurrence of a magnetic field around the cathode beam was still uncertain at the time. The mere fact was denied by many scientists. Besides providing confirmation for the occurrence of the magnetic field, Joffé succeeded in showing that the field intensity was akin to that of an equivalent current in a metal conductor.

At the beginning of the 'twenties, the advent of quantum mechanics, Joffé reverted to his 1912 experiments and found that metal dust particles irradiated by X-rays emitted electrons. These experiments, carried out with Dr. Dobronravov, gave convincing proof that the energy of electrons emitted by dust particles corresponds to that of X-ray quanta.

However, the main trend of Joffé's theoretical and experimental works throughout his life was in the direction of electrical and mechanical properties of dielectrics and semi-conductors. He may with full justice be considered among the pioneers of the physics of solids. His earliest scientific investigations dealt with elastic and electric properties of quartz. In 1922, while investigating the plastic strain in crystals, Joffé and Kirpicheva discovered that the spots of the Laue diffraction pattern were extended into radial stripes as soon as the elastic limit was exceeded. This was evidence that plastic strain leads to the breaking up of a crystal into differently oriented blocks.

Joffé's disciples extended his investigations to a great variety of crystal bodies, and their work obtained world-wide appreciation. A new trend in the physics of metals arose and was successfully developed.

Another line of experimental investigation pursued by Joffé provided a basis for the theory of crystal strength. Prior to these experiments there was a large discrepancy between the values of crystal strength obtained experimentally and those calculated on the crystal lattice theory. For example, the theoretical limiting value for rocksalt crystals was found to be several hundreds of kgm./cm.^{2}, whereas experiment gave a limit of hundreds of gm./cm.^{2}. Measurements of rocksalt crystals immersed in water and similar experiments carried out with balls of rocksalt cooled in liquid air which were immersed in boiling water or molten tin showed that under these conditions the limiting strength was close to the theoretical order. The low limit observed before was ascribed to microcracks and other crystal defects.

Another important discovery was made by Joffé when investigating the mechanical properties of crystals. He found that the nature of brittle or plastic destruction of crystals at a given temperature was determined by the relation between the temperature-dependent yield strength and the ultimate tension which is only slightly dependent on temperature. This relation, established later for a number of industrial materials, led to many conclusions of great practical value.

PHYSICS DEPARTMENTAL LIBRARY

Of extreme importance were Joffé's investigations on electric properties of dielectrics. Prior to his experiments, all electric phenomena displayed by dielectrics were considered as a sort of agglomeration of anomalies. Joffé found that thin polarization layers were formed at the electrode surfaces during the passage of current through a dielectric crystal. The potential difference of these layers appeared to be enormous. By allowing for polarization, Joffé showed that the flow of current through a crystal was in strict obedience to Ohm's law. Joffé was the first to discover (in 1916) that the conductivity of the majority of ionic crystals was of an electrolytic nature and due in part to lattice-occluded impurities and in part to thermal dissociation of the lattice.

Joffé and his disciples have conducted a vast amount of work on dielectric breakdown, in particular on breakdown stress as a function of the thickness of the dielectric material. These investigations were of great importance for the technology of insulating materials.

From 1930 Joffé's interests began to concentrate on semi-conductors. Even then, Joffé was aware of the importance of semi-conductors for engineering problems. Joffé himself and his co-workers were very successful in this field and discovered a number of fundamental facts in the physics of semi-conductors. First of all considerable attention was paid to the working out of techniques for obtaining physical values characteristic of semi-conductors, such as the concentration of carriers, their charge, mobility, etc. Most important was the discovery of the effect of impurities on electric properties of semi-conductors. It was shown, moreover, that an excess or a deficiency in some component may exhibit an effect similar to that of an impurity. It appeared, for example, that lead sulphide containing an excess of lead atoms was a conductor of the n-type, whereas a sulphur excess would make it p-type. Joffé suggested that these facts were due to impurity or excess atoms either creating additional electron sources or picking up electrons with consequent formation of holes. The concept of electron-or hole-semi-conductors, now defined as n- and p-type, seems to have originated from Joffé's laboratory.

Towards the end of the 'thirties Joffé, together with his wife, proposed a mechanism of rectification which is now widely accepted. It implies that the barrier-layer in rectifiers is formed at the p-n junction. The flow of current is due to electrons and holes approaching each other and recombining at the junction. When the electrons and holes drift apart, the resistivity of the layer adjacent to the junction is raised and the latter consequently becomes a barrier-layer.

Of the many practical applications of semi-conductors Joffé considered as paramount the utilization of their thermoelectric and photoelectric properties for conversion of heat and light energy into electric energy. Joffé's theory of thermoelectric generators (and thermoelectric refrigerators) opened a clear path for physicists and engineers working in this field. The idea of plasma thermoelectricity, now being developed in many countries, was also set forth by Joffé.

His great achievements in this domain were emphasized by the eminent American scientist J. Bardeen at the International Conference on the Physics of Semi-Conductors in Rochester, 1959. In his inaugural speech Bardeen said: "The first real scientific study of electron mobility, thermal conductivity, and other factors important for thermal elements, and the way they depend on composition was made by Joffé and his co-workers. Results they have obtained clearly demonstrate the virtue of the scientific over the purely empirical approach. . . . . Research on thermoelectric effects and on thermal conduction in semi-conductors has yielded a number of interesting phenomena, involving phonon scattering, phonon drag, and heat transfer by ambipolar diffusion".

A profound and eager concern for all problems of physics and adjacent fields was very characteristic of Joffé as a scientist. A great number of Joffé's ideas, developed later by his disciples, date back to the 'twenties and 'thirties; they laid the foundation for the development in the U.S.S.R. of modern trends of physical science. Joffé acknowledged his authorship only in investigations that were carried out with his own hands. He was never prone to put his name to papers dealing with investigations that were carried out by his numerous disciples, even though the ideas and guidance were his. This makes his contribution to science, embracing a great variety of physical fields (nuclear physics, chemical physics, the theory of metals, physics of heat, etc), even larger than it would seem at first.

He created a widely spread school of Soviet physicists dealing with most diverse trends in physics and related sciences. His gift for inspiring his colleagues, especially young ones, with a passionate interest for science was truly remarkable.

Sixteen new institutes were founded under Joffé's sponsorship. In 1918 he created the Physico-Technical Institute of Leningrad, which played an exceptionally important part in the development of physics. He was director of this Institute for more than thirty years, but his activities reached far beyond its scope. He took part in the development of physics all over the country, and his was the idea of a widely spread system of physico-technical institutes and laboratories that would serve as a scientific basis for the growing industry. He contributed largely to the organization of physical institutes in Kharkov, Dnyeporpetrovsk, Tomsk, Sverdlovsk. Groups of able scientists were chosen by him from his staff for work in each of these institutes, thus forming the nuclei of future scientific bodies. The Institute of Chemical Physics in Moscow and the Electro-Physical Institute in Leningrad sprang up from the Leningrad Physico-Technical Institute. The Institute of Physical Agriculture, so far the only one of its kind, was also founded by Joffé. An outstanding Physico-Mechanical Department of an entirely novel type was created by Joffé in the Leningrad Polytechnic Institute. Its programme combines deep penetration into theory with most lively actual practice. Engineers coming from this department possess a profound knowledge of modern physics and are carrying the latest scientific achievements to all fields of industry.

Joffé's remarkable personality, his immense scientific prestige and wide erudition, his unquenchable passionate love for science, his gift for inspiring his disciples, his rare simplicity and affability won him respect and affection among the widest circles of scientists and engineers of the Soviet Union, deep friendship on the part of his disciples, including the present writers. The strongest bonds of friendship tied him with eminent scientists of many countries. It will be hard for all who knew him to accept the fact that he is no more, that the hearty man who seemed unaware of age, so full of the joy of life and far-reaching projects, has gone, that the tireless, wonderful intellect has ceased to exist.

N. N. Semenov
V. N. Kondratiev

Prof. C. W. Dannatt

Prof. Cecil William Dannatt, who died at his home in Blackheath on April 9, was born on August 2, 1892. He was educated at Colfe's Grammar School and the Royal School of Mines, where he graduated in metallurgy in July 1914. In August of the same year he enlisted in the Queen's Westminster Rifles. He received a commission in 1915 and served in France, Salonika and Palestine. On being demobilized in 1918, he joined the Ministry of the Interior, Cairo, as assistant director of the Technical Section of the Public Security Department. After two years of very varied experience in this post, he went to Trinidad as geologist to an oil company, but in 1923 he returned to the Royal School of Mines, to work as a research student in the Metallurgy Department. A few months later he joined the teaching staff of the Department, and the work was so much to his liking, and he so well fitted for it, that he remained on the staff for thirty-four years, first as demonstrator, then lecturer, reader, acting director and finally, from 1945 until his retirement in 1957, professor and head of the Metallurgy Department.

Throughout his long connexion with the Royal School of Mines and Imperial College, and particularly after his appointment as professor, he devoted himself to the advancement of the Department, and the training and education of his students, in every one of whom he took a personal and sincere interest. Under his leadership, the Department added continuously to its reputation as a centre of learning and research, and when he handed over to his successor in 1957 he was able to do so in the knowledge that its standing had never been higher. Although his interests and knowledge extended to all branches of metallurgy, and he was a vigorous opponent of specialization within his Department, his greatest interest was in fact in the scientific and technological aspects of the extraction of metals from their ores, and the achievement that afforded him more gratification than any other was the formation of the Nuffield Research Group in Extraction Metallurgy. He was largely responsible for the establishment of this group in his Department in 1950, since when, with his active support, it has developed into the leading academic research school devoted to the study of metallurgical processes at high temperatures.

Prof. Dannatt had a charming and gracious personality, and he was an unsparing worker. He was always anxious to help, and always reluctant to refuse any request for advice or information, or demand for his services. Scientific societies, professional institutions, educational and examining bodies, and Government, college and university committees made many such demands not just on account of his position but also because his wide knowledge, alert mind and ability to express himself lucidly and concisely were powerful assets in committee work. He particularly valued his long association with the Institution of Mining and Metallurgy, of which he was president during 1956–57, the Institution of Metallurgists, of which he was vice-president during 1953–57, the Sir John Cass College and Woolwich Polytechnic, as member of their governing bodies, and the City and Guilds of London Institute, as member of the General Advisory Committee and Moderating Committee for Metallurgical Subjects.

Shortly after his retirement, the title of professor emeritus of metallurgy was conferred on him by the University of London, and in 1960 he became a Fellow of the Imperial College. Although incapacitated by a prolonged and severe illness, he retained his interest in metallurgy to the end. He is survived by his widow and daughter.

M. S. Fisher

Prof. J. Bordet, For.Mem.R.S.

Jules Bordet, who died at his home in Ixelles in Belgium on April 6, was a pioneer in the science of microbiology and the allied one of immunology. The last twenty-five years of his life—he died at the age of ninety—were spent in retirement and he had used the early years of this period of leisure to prepare a second edition of his excellent text-book, *Traité de l'Immunité dans les Maladies Infectieuses*, which appeared in 1939. But in the closing years of the past century and the first thirty years of this one, Bordet's brilliant mind and experimental skill led to discoveries of fundamental importance and a flow of scientific papers which established for him an indisputable claim to fame.

Bordet was born in Soignies, Belgium, on June 13, 1870. Electing to enter the profession of medicine, he studied at the University of Brussels, graduating M.D. in 1892. Choosing a laboratory career, he went to the Pasteur Institute, Paris, in 1894, and worked there for seven years, being recalled in 1901 to become first director of the newly founded Pasteur Institute, Brussels. Six years later he was appointed to the chair of bacteriology in the University of Brussels, holding this post until his retirement in 1935.

Bordet's inquiring mind led to his study of many aspects of microbiology, among others, anaerobiosis, bacterial agglutination, the pleuropneumonia group of micro-organisms and the bacteriophages, on all of which he made valuable original observations. It was, however, his investigations into the ætiology of whooping-cough and his elaboration of the complement-fixation test, in both of which he had the assistance of his colleague, Gengou, that stood out above the rest. It was he and Gengou who, in 1906, discovered the causal agent of whooping-cough—*Haemophilus pertussis*—a discovery which has made possible the specific prophylaxis of this disease; and it was at the end of the last century, in 1895 to be precise, that he published his first paper on bacteriolysis, showing that lysis of a bacterium by an immune serum was the work of two serum components, specific heat-stable antibody and non-specific heat-labile complement. It was from this observation, of course, that the complement-fixation test emerged (1901), with its wide application in the diagnosis of disease.

Recognition of the value of these researches brought Bordet many honours. In 1911 he was given the Prix de la Ville, Paris, and two years later the Swedish Medical Society awarded him the Hansen Prize and the Pasteur Medal. He was made a foreign member of the Royal Society in 1916, and in 1919 he was given the Nobel Prize for medicine and physiology; the University of Cambridge conferred on him the honorary degree of M.D. Bordet was married and had three children, a son and two daughters.

S. P. Bedson

NEWS and VIEWS

Medical Statistics in the London School of Hygiene and Tropical Medicine: Prof. A. Bradford Hill

PROF. A. BRADFORD HILL retires from the chair of medical statistics at the London School of Hygiene and Tropical Medicine at the end of the current academic year. As a son of the late Sir Leonard Hill he has inherited perspicacity and sharpness of wit, but he has made his own very distinctive contributions to medicine and to statistics. He joined the staff of the Medical Research Council and its Industrial Health Research Board in 1923, and soon immersed himself in problems of industrial sickness. His surveys of sickness in the cotton spinning, cotton weaving and printing industries immediately became standard references, and early in this period he read to the Royal Statistical Society a classical paper on the effect of internal movement of population on local mortality. In 1933, Hill became reader in epidemiology and vital statistics in the University of London and set himself to understand doctors and their problems and to teach them what he calls "arithmetic with logic". He was pre-eminently successful in both tasks. In 1937, he published *Principles of Medical Statistics*, a text-book which still occupies an unchallenged place, is in its sixth edition in English and has been translated into other languages. Since 1945, Hill has been professor of medical statistics in the London School of Hygiene and Tropical Medicine and director of the Statistical Research Unit of the Medical Research Council. His interest and experience in the conduct of the controlled clinical trial are probably unique, and he has set very high standards for his unit. Any research worker who survives Hill's devil's advocacy can be sure his experiment is properly designed; he can also be sure of warm encouragement and help. Hill has been widely honoured, being elected a Fellow of the Royal Society (1954), president of the Royal Statistical Society from 1950 until 1952 (to which he gave much time and energy as honorary secretary during 1940–50) and its gold medallist in 1953; president of the Section of Epidemiology, Royal Society of Medicine 1953–55, and member of the International Statistical Institute.

Prof. P. Armitage

DR. PETER ARMITAGE who, at thirty-seven, succeeds Prof. Bradford Hill in the chair of medical statistics is a mathematical graduate of Cambridge. His studies were interrupted by the War and he went to the Ministry of Supply Statistical Advisory Department during 1943–45, and later to the Mathematics Division of the National Physical Laboratory. In 1947 he joined the Statistical Research Unit of the Medical Research Council. Dr. Armitage has contributed much to recent advances in mathematical statistics, especially in their application to prophylactic and therapeutic trials. In particular he has developed the sequential method as a highly effective tool and has recently published an excellent text-book, *Sequential Medical Trials*. Dr. Armitage is, like his predecessor, unstinting in his efforts to further the cause of the Royal Statistical Society; he has been a member of the Council since 1954 and an honorary secretary from 1958.

Pharmacy at the Royal College of Science and Technology, Glasgow: Prof. J. P. Todd

PROF. JAMES P. TODD, who retires at the end of this session, was appointed to the newly constituted School of Pharmacy in the Royal College of Science and Technology, Glasgow, in 1921 as its sole lecturer. The growth of the School to its present proportions is a remarkable tribute to his foresight and able direction. The first courses offered were those leading to the examinations of the Pharmaceutical Society, but in 1924 the first student was enrolled for the degree of B.Sc. in pharmacy of the University of Glasgow, which had been instituted in 1907, and teaching for this degree began in the School under the Ordinance of Affiliation. Todd was awarded a Ph.D. in 1932, and in 1937 was appointed professor of pharmacy, this being the first chair of pharmacy in the United Kingdom. His responsibilities also included the Departments of Botany and Bacteriology, and the Scottish School of Bakery. Much of the credit for the development of these disciplines to the status of full departments with separate chairs in food science and in applied microbiology and biology belongs to Prof. Todd. No record of his achievements would be complete without mention of his work during the War years, when infusion fluid and blood transfusion units were set up in the College under his direction. The permanent West of Scotland Region Blood Transfusion Service stands as a lasting reminder of this period of his career. His studies of bacterial pyrogens, which later became a major interest, stemmed directly from this work, and he is now recognized as a leading authority on this subject.

Prof. J. B. Stenlake

DR. JOHN B. STENLAKE, who is to succeed Prof. J. P. Todd, was educated at Ealing Grammar School. He then served an apprenticeship in pharmacy before proceeding on a Jacob Bell Memorial Scholarship to the College of the Pharmaceutical Society, where he qualified as a pharmaceutical chemist in 1941 and was awarded the Pereira Medal. After war service in the Royal Air Force, he joined the teaching staff of the School of Pharmacy of the University of London, and during this period graduated B.Sc. with honours in chemistry. In 1950 he was awarded a Ph.D. degree by the University of London and a D.Sc. (London) in 1960, for work in the field of medicinal and pharmaceutical chemistry. Since 1952 he has held the appointment of senior lecturer in pharmaceutical chemistry in the School of Pharmacy of the Royal College of Science and Technology. He will take up his new post on September 1.

Applied Microbiology and Biology at the Royal College of Science and Technology, Glasgow: Prof. E. O. Morris

DR. ERNEST O. MORRIS has been appointed to the new chair of applied microbiology and biology at the Royal College of Science and Technology, Glasgow, and will take office as from September 1. Dr. Morris was educated at the Handsworth Junior Technical School, Birmingham, and, during 1929–39, worked as a laboratory technician in a hospital and in the Departments of Cancer Research and of Pathology and Bacteriology in the University of Birmingham. During this time he qualified as an associate of the Institute of Medical Laboratory Technology. In 1939 he was mobilized with the Territorial Army and served with the Royal Army Medical Corps in France, Assam and India. Later he served on the staff of General Headquarters at the Central Military Laboratory, Poona, where he assisted in the training of army personnel in medical laboratory technology. After demobilization he matriculated at the University of Birmingham, where he graduated with honours in bacteriology in 1950. In 1952 he was awarded a Ph.D. at the University of Birmingham for work on the bacterial flora of the mouth in relation to dental caries. Following this he became head of the Microbiological Division at the Brewing Industry Research Foundation under the directorship of Sir Ian M. Heilbron, a post he held until 1956. During this period his own research interests ranged from fundamental studies of the physiology of yeasts to the development of techniques for use in the fermentation industries. In 1956 he was appointed lecturer in the Microbiological Division of the School of Pharmacy, Royal College of Science and Technology, and principal lecturer in that Division in 1959. When the Divisions of Microbiology, Biology and Biochemistry in the School of Pharmacy were formed into the Department of Applied Microbiology and Biology, Dr. Morris was appointed head of the new Department.

Zoology at the Banaras Hindu University: Prof. S. P. Ray-Chaudhuri

Dr. S. P. Ray-Chaudhuri has been appointed to the chair of zoology at the Banaras Hindu University, Varanasi, India. He obtained his Ph.D. in the University of Edinburgh, working with Prof. H. J. Muller on the effects of radiation on the fruit-fly *Drosophila*, and has been engaged in teaching at the University of Calcutta since 1941. Dr. Ray-Chaudhuri was elected a Fellow of the National Institute of Science of India in 1950, and was the president of the Zoological Section of the Indian Science Congress in 1960. He is well known for his contributions to radiobiological research.

Commonwealth Technical Training Week

In Great Britain, Commonwealth Technical Training Week is to be held during May 29–June 3, 1961. In Aden, Hong Kong, Nigeria, Malaya and Pakistan the week will have been celebrated before this date and will have carried appropriate messages from H.R.H. the Duke of Edinburgh. In the United Kingdom support is almost universal. In England and Scotland possibly seven areas may not take part, but both Wales and Northern Ireland have each achieved 100 per cent participation. A special exhibition at the Royal Exchange, London, is being arranged by the City and Guilds of London Institute in co-operation with the City of London, the City Livery Companies and the London County Council. The exhibition will illustrate the opportunities for training and education in industry, commerce and the professions. Most of the exhibits will be provided by organizations which are nationally representative of the major groupings in industry and commerce, while the City Livery Companies will provide exhibits illustrating the historic background of training and craftsmanship. The Duke of Edinburgh has recorded a short address for use at the opening ceremonies. His Royal Highness, speaking from the dairy at Windsor Castle, has also contributed a lively introduction and epilogue to the film "Training To-day for To-morrow".

U.S. Antarctic Research Ship *Eltanin*

The U.S.N.S. *Eltanin*, an ice-strengthened cargo ship, is to be equipped as a sea-going scientific laboratory for the U.S. Antarctic Research Programme. It is expected that the first research cruise will begin in the later autumn of 1961. The ship will be fitted to accommodate numerous disciplines, including meteorology, upper atmosphere studies, marine and terrestrial biology, physical oceanography, submarine geology, and geomagnetic studies. The cost of conversion will be borne principally by the National Science Foundation; the Military Sea Transportation Service will supervise the ship's modification. The *Eltanin* will continue to be owned and operated by the Military Sea Transport Service. The National Science Foundation, as sponsor of the ship, will be responsible for the scientific programme and will designate a senior scientist aboard. It is expected that the ship will work in Antarctic waters at least ten months a year. Individual cruises will vary from one to two or more months in length, depending on the research in progress. During refuelling calls at southern hemisphere ports, scientists will be able to change equipment for experiments.

British Leather Manufacturers' Research Association : Open Days

The work exhibited during the 1961 open days (May 2–4) in the laboratories of the British Leather Manufacturers' Research Association at Milton Park, Egham, mostly showed developments from last year's programme (see *Nature*, 186, 1024; 1960). Work on the mechanical properties of collagen and leather fibres has continued. An automatic amino-acid analyser (Bender and Hobein) has been installed for work on the protein constituents of skin. A synthetic approach to tanning chemistry, involving the preparation of phenolic glucosides and sugar esters, has been commenced. Considerable progress has been made in the use of enzyme preparations in place of the traditional milk of lime plus sodium sulphide bath, for loosening hair or wool in preparing skins for tanning. The work (sponsored by the U.S. Department of Agriculture) on the deterioration of leather by perspiration and warm, damp conditions has also advanced considerably, and some aspects of the problem have been solved. In the section on dyeing, two topics were illustrated: improving regularity of shade by finding how to control the dyeing process more precisely and improving the products from the users' point of view, for example, the problem of loose colour in suede leather. Development of performance trials for assessing the reliability of laboratory tests of physical properties has continued, particularly in the work on waterproofing leather. The 'effluent liaison' section, which advises on the application of existing knowledge to the effluent problems of the leather industry (*Nature*, 187, 992; 1960) is now in full operation and the apparatus used by the mobile laboratory was shown. A substantial part of the Association's effort is devoted to liaison activities (member services) of various kinds, and between 700 and 800 production problems are investigated each year for member firms.

British Hat and Allied Feltmakers Research Association

The thirteenth annual report of the Director of Research, British Hat and Allied Feltmakers Research Association, covering the year ended August 1960, refers to considerable effort in the production of control charts for members (Pp. 20. Droylsden, Manchester: British Hat and Allied Feltmakers Research Association, 1961). Work on the storing of carroted rabbit skins was continued, and a literature survey of information published on the carroting of fur during the past ten years was issued to members. Work also continued on the possible applications to fur felt of classes of dyes other than the acid-levelling type, and acid-milling and the 1 : 1 and 1 : 2-premetallized colours have been applied successfully on a small-scale cone-dyeing machine with the aid of proprietary dyeing assistants, giving improved fastness properties. Work on the effect of pressure, moisture and temperature on pressing performance has led to the definition of limits for each, and the limits of accuracy required in the dimensions of blocks and press-dishes to give specified hat sizes have also been studied and defined. A start has been made on the measurement of the coefficient of friction of wool felt with other materials when immersed in water and aqueous solutions, and results obtained in measurements of the shock absorption behaviour of felt against other materials, such as sponge rubber and foam plastics, are being analysed to resolve differences which are believed to be fundamental to the problem of shock absorption.

Protection of Workers against Unsealed Radioactive Substances

Requirements for the protection of persons employed in factories (and other places to which the Factories Act, 1937, applies) against ionizing radiations and other hazards arising from the use of unsealed radioactive substances are set out in a recent publication issued by the Ministry of Labour (*Unsealed Radioactive Substances Regulations* (*Preliminary Draft of Regulations*). Pp. 28. (London: H.M.S.O., 1961.) 1*s*. 3*d*. net.) This draft, called the 'Unsealed Radioactive Substances Regulations', is a complementary code to the statutory draft of regulations recently published dealing with the protection of workers from dangers arising from the use of 'sealed sources' of radioactive substances, and from machines which produce ionizing radiations. It has been prepared by the Ministry of Labour with the help and advice of an *ad hoc* committee appointed to advise the Chief Inspector of Factories on the subject, by the Advisory Panel on Radiological Problems in Industry, and by the General Purposes Committee of the Radioactive Substances Advisory Committee. The proposed regulations will apply to the whole range of radionuclides used in industry, including those used in nuclear reactors, and they will, in time, replace the 'luminizing regulations' made in 1947. Unsealed radioactive substances are defined by the regulations to include nuclear fuel-elements. Maximum permissible doses, based on the recommendations of the International Committee on Radiological Protection, and supported by the Medical Research Council, are laid down. Provision is made for reliance to be placed on working arrangements that provide intrinsic safety, for the instruction of workers concerned with the hazards involved and the precautions to be taken, and also for medical supervision. The Ministry invites observations on the draft regulations. These should be sent to 8 St. James's Square, London, S.W.1.

Rise in Population in Britain

The *Quarterly Return* of the Registrar General for the fourth quarter of 1960 gives the provisional figures for that year. Births, at 783,000, were 32,000 up on the previous year and 118,000 higher than in 1955, since when the figure has been steadily rising. The crude birth-rate at 17·1 per thousand was the highest since 1948, and the figures will present considerable problems for educational planners later in the 1960's. Infant mortality, at 21·7 per 1,000, is the lowest on record, and the nineteen-fifties have seen a fall in this index of one-third. Neo-natal mortality and peri-natal mortality have also fallen. The continued rise in births is an interesting phenomenon, and it will be necessary to await the detailed statistics to see whether the rise implies an increase in family size or merely a shift in timing. The population projections which are a feature of the *Quarterly Return* have been modified to take account of the rising number of births, and imply an increase in the population by 10 millions to 56 millions by the end of the century.

Water Research

Recent issues of the periodical published by the Water Research Association contain articles surveying two widely different subjects of interest to all concerned with the provision of public water supplies. It is well known that water supplies containing undue concentrations of nitrate are dangerous to infants because of a reaction between the nitrate and hæmoglobin in the blood. It is clear from the article in *Water Research News* (No. 10) that considerable research is required before the mechanism of this reaction can be fully understood. It does not appear likely that the nitrate can oxidize the hæmoglobin directly, and it is suggested that its effect is due to blocking of an enzyme system. No. 11 of *Water Research News* is devoted largely to a discussion of the mechanism of the coagulation process, which is of fundamental importance in the production of clear water supplies. In this case the article contains an account of the results of research work, and is primarily concerned with the effect of *p*H value on coagulation by aluminium sulphate; it is a summary of fuller technical papers on the subject.

The American Type Culture Collection

The American Type Culture Collection, Washington, D.C., has been given a grant of 865,500 dollars by the National Science Foundation towards the construction of a new building to house its collection of micro-organisms used in research and teaching. The Collection at present includes more than 5,000 strains of bacteria, yeasts, moulds, algae, protozoa and animal, plant and bacterial viruses. These materials, besides being of great importance for biological, medical, agricultural and industrial research and for training of personnel in the biological and medical sciences, also serve as standards for comparison with micro-organisms isolated from natural sources, and are employed for the assay and production of drugs, enzymes and other chemicals. During 1960, more than 12,000 cultures were distributed to various institutions. The new building, which, according to preliminary plans, will be of about 30,000 sq. ft., will provide working space for about sixty people, including scientists, technicians, research assistants, etc. The estimated cost of the new building is 1,046,000 dollars. The Collection has received a grant of 90,278 dollars from the National Institutes of Health, and, in addition, about 150,000 dollars has been raised from private industry.

Co-operation between University and Industry in Manchester

THE Manchester Joint Research Council, established in 1944 as a co-operative effort between the University of Manchester and the Manchester Chamber of Commerce, now regards its most useful function as the extension of direct contact with local firms, particularly those small and medium-sized firms which depend on science and technology. As a basis for the necessary liaison work the Council has published two booklets. One of these is entitled *An Account of Some of the Scientific and Technological Facilities which Manchester University and the Manchester College of Science and Technology can offer to Industry*, and includes an indication of some of the research work carried out by the different departments (Pp. 19. Manchester: Manchester Joint Research Council, 1960). The other booklet is entitled *Sources of Scientific and Technical Information Available to Local Industry* (Pp. 21. Manchester: Manchester Joint Research Council, 1960). This appears to be less satisfactory than the first booklet: while there is a list of the research establishments of the Department of Scientific and Industrial Research, and of the Research Associations, and a list of some organizations which will name consultant experts in particular fields, publications are not covered, and under library services the only references are to the Manchester Technical Library and to Aslib.

Journal of Atherosclerosis Research

ATHEROSCLEROSIS is being studied nowadays by workers in a wide diversity of fields, and the results of their studies are appearing in many different journals. To try to co-ordinate publications on the disease, a new journal has been started (*J. Atherosclerosis Res.*, Elsevier, Amsterdam, bi-monthly, price £6 5*s*. a year). The editorial board contains members from more than a dozen countries, and the journal will contain review articles, research reports and short communications—usually in the English language. Communications on subjects related to atherosclerosis (for example, thrombosis) will also be accepted. The first part (January–February 1961) includes a review on morphological aspects of the disease by Prof. T. Crawford, and one on the thyroid and atherosclerosis by Dr. G. S. Boyd. Manuscripts may be sent to the editorial secretary, Dr. F. P. Woodford, Witte Singel 36, Leyden, The Netherlands, or to any member of the editorial board.

Life-History of the Green-veined Orchid

THE vast field of work for amateur naturalists is brought out by the continuous efforts of a schoolboy, J. F. H. Doulton, over the past three years, in the Report of the Rugby School Natural History Society for 1960 (Pp. 16. (94th issue). Rugby: George Over, Ltd., 1961). Doulton investigated the life-history of the green-veined orchid, *Orchis morio*. A quadrat was marked out, and, each year, all the plants of *O. morio* were marked on a map, together with a note of whether they were producing leaf or flowers. It is hoped to continue this work in the future to trace the life-histories of individual plants over a number of years, but it is already possible to draw tentative conclusions about the sequence of leaf and flower production. The general conclusions are that plants which have flowered do not do so again, at least in the first or second year after flowering; they are more likely to die after flowering than after being in leaf; their average life is four years; they are less likely to flower in their first year than in subsequent years. Several additional points must be taken into account when assessing these results. First, it is difficult in many cases to be sure that the investigator is following the same plant over several years because plants may come up in slightly different places, and the place of one plant may be taken by another. Secondly, there are five cases in which a plant has apparently remained dormant for a year; and it is possible that this behaviour may be more widespread, in which case some of the above conclusions may need modifying. Lastly, the observations refer only to plants producing conspicuous leaves or flowers and not to any previous year's growth as mycorhizome. Experiments on the removal of flower heads suggest that removal of flower heads before seed can be set makes it quite likely that the plant will flower again in the next two years.

Primitive Rock-Shelter Art in Australia

THERE is no doubt that interest in the Australian rock-shelter art is booming. Barely have notes on one publication been written before another is to hand. The *Journal of the Royal Society of Western Australia* (43, Pt. 4, 1961), among other articles, contains an account by P. E. Playford of rock paintings in the West Kimberley region of Western Australia. The article is illustrated with six full-page reproductions of the paintings. The local tribes know of the painted localities, but, while in some cases they tell stories about them, they say that they are the work of aborigines long ago. The paintings themselves include crude figures of animals and human beings, frogs, serpents, lizards, emus, crocodiles and kangaroos. The descriptive section of the article not only records localities but also attempts to explain some of the groups in terms of the myths obtained by questioning the local inhabitants. The article is one which will be welcomed by all students interested in this 'prehistoric' yet not very ancient rock-shelter art of Australia.

Termites and Coal Seams in Angola

IN England coal miners looking for outcrops often used to examine rabbit holes for signs of coal dust; a German firm of consulting engineers is seeking to assess Angola's resources in brown coal by studying the ant-hills built up by colonies of termites (*Science Afrique*, No. 22; October 1960). The theory is that termites prefer to build on lignite foundations and use the lignite as building material because its low-heat conductivity "keeps the house cool". They take the local light-coloured clay only as an outer covering to reflect away the heat of the sun. If the theory should prove to be sound, Angola with its countless termite hills may have big deposits of lignite. The nearest hard-coal mines are more than 500 miles away in Rhodesia, and locomotives on the country's railways still use wood as fuel. The assumption is that this might, with advantage, be replaced by briquettes made from brown coal.

Geology of British Borneo

AN important monograph on *The Geology of Sarawak, Brunei and the Western Part of North Borneo* has recently been published by the Government Printer in Sarawak, sponsored by the Directorate of Overseas Geological Surveys. Since the discovery of the Miri oilfield in 1910, very large sums have been spent by the Royal Dutch Shell Group in geological explorations throughout British Borneo, culminating in an expenditure of close on £20 million in the decade 1949–58. The geology of the territories, no greater in size than England and Wales, is thus known in considerable detail. A Government Geological Survey was established in 1949, to which the reports of the oil companies were at once made available; and it is a reflexion of the happy relationships between Government and industry that this official monograph has been compiled by Dr. P. Liechti, of "Shell", in association with Dr. F. W. Roe and Dr. N. S. Haile, of the Geological Survey. The accompanying tectonic map (1: 1,000,000) and geological maps (1: 500,000) have been excellently colour-printed in the Netherlands. Congratulations are due to the authors, to their parent organizations, and to the Government Printer in Kuching for the production of a lucid description of a region of outstanding geological interest (Bulletin 3. Vol. 1 (Text): Pp. xvii + 360 + 73 plates. Vol. 2 (Portfolio). Table of Rock-Stratigraphic Columnar Sections. Tectonic Map. (Kuching, Sarawak: Government Printing Office; London: Overseas Geological Surveys.) 1960. 21 Malayan dollars; 49*s*. the two volumes).

Beit Memorial Fellowships

THE Trustees of the Beit Memorial Fellowships for Medical Research, in their report, announce that Prof. Alexander Haddow has been elected a member of the Advisory Board. The following elections have also been made: *Junior Fellowships*, to S. P. R. Rose, to investigate the properties and localization of certain enzymes associated with the active transport of ions across cellular membranes in nervous tissue, at the Department of Biochemistry, University of Oxford; Dr. R. Laverty, to investigate the action of drugs on catechol-amines in the central and sympathetic nervous systems, at the Agricultural Research Council's Institute for Animal Physiology, Babraham; Dr. Ruth F. Itzhaki, to investigate the radiosensitivity of deoxyribonucleoprotein under various conditions with the view of explaining the action of radiation on malignant tissues, at the Department of Radiotherapeutics, University of Cambridge; C. W. F. McClare, to investigate energy transfer in nucleic acids, at the Department of Radiotherapeutics, University of Cambridge; S. S. Hayreh, to investigate experimentally the pathogenesis of papillœdema, at the Institute of Ophthalmology, London. *Fourth-year Fellowship*, to Margarethe M. A. Holzbauer-Sharman, to enable her to continue investigations into the mechanisms involved in the increase in the secretion of aldosterone following hæmorrhage.

American Academy of Arts and Sciences: Grants-in-aid

GRANTS-IN-AID, ranging between 500 dollars and 1,500 dollars, are available from funds administered by the American Academy of Arts and Sciences for research in any recognized scientific field, including mathematics, physics, biology and the social sciences. Applications must be received before September 1 for grants to be made in October. In general, applications from individual scientists rather than from institutions are favoured, although this is not an inflexible policy. Support is not usually given for work aimed primarily at fulfilling the requirements of an academic degree. Further information and application forms can be obtained from the American Academy of Arts and Sciences, Committees on Research Funds, 280 Newton Street, Brookline Station 46, Boston, Mass.

Lederle Medical Faculty Awards

THE Lederle Laboratories Division of the American Cyanamid Company is making available a number of medical faculty awards which will begin with the academic year 1962–63. These awards are intended only for individuals who share in all departmental responsibilities, particularly in the teaching of undergraduate medical students. They are not intended to be research fellowships, or for the support of individuals whose only or major function and interest is in the conduct or supervision of research activities. Also, these awards are not intended for assistance of research departments or divisions of postgraduate medical schools. The awards are primarily intended to assist medical schools in providing for their major clinical disciplines individuals who, having demonstrated ability and interest in teaching and research, will devote their major efforts to the teaching of clinical medicine with the view of integrating the knowledge and principles of the biological sciences, as applied to man. Further information can be obtained from the Lederle Medical Faculty Awards, Office of the Secretary, Pearl River, New York.

Graduate Course in Electrical Machines

THE University of Birmingham is organizing a graduate course, lasting twelve months as from October 1, on "Electrical Machines". The course is available to honours graduates in electrical engineering who have, preferably, had a year or two of engineering experience outside the university. The syllabus for the course consists of five major sections: (1) electromechanical energy conversion; (2) analysis of rotating machines; (3) mathematical techniques; (4) either electrical properties of materials, or electronic computers (analogue and digital); (5) automatic control systems. The fee for this course will be £81. Further information can be obtained from the Graduate Course Supervisor, Electrical Engineering Department, the University, Edgbaston, Birmingham 15.

The Tenth International Botanical Congress, Edinburgh, 1964

AT a meeting of the ninth International Botanical Congress in Montreal in 1959 it was suggested that the tenth Congress might be held in the United Kingdom in 1964. On the recommendation of the British National Committee for Biology, the Royal Society of London on behalf of all host organizations suggested that the tenth International Botanical Congress should be held in Edinburgh during August 3–12, 1964. Representatives were invited from universities, research institutes and biological societies to a meeting in the Senate Hall of the Old College, Edinburgh, on March 22, 1961. Prof. H. Godwin, of the University of Cambridge, has been elected president of the Congress. Joint secretaries of the Executive Committee, which is to be concerned with the preparation and planning of the Congress, will be Prof. G. E. Fogg, Department of Botany, Westfield College, Hampstead, London, N.W.3, and Dr. A. J. Brook, Department of Botany, University of Edinburgh, at the Royal Botanic Garden, Edinburgh 3.

The Night Sky in June

New moon occurs on June 13d. 05h. 17m. U.T. and full moon on June 28d. 12h. 38m. The following conjunctions with the Moon take place: June 2d. 18h., Saturn 3° S.; June 3d. 06h., Jupiter 3° S.; June 9d. 09h., Venus 2° N.; June 18d. 10h., Mars 2° N.; June 18d. 20h., Regulus 0·5° N.; June 30d. 00h. Saturn 3° S.; June 30d. 12h., Jupiter 3° S. In addition to these conjunctions with the Moon, Mars is in conjunction with Regulus on June 27d. 08h., Mars being 0·7° N. Mercury is an evening star, visible during the first few days of the month low in the west after sunset; later in the month it is too close to the Sun for observation. Venus is a morning star, rising at 2h. 15m., 1h. 50m. and 1h. 25m., on June 1, 15 and 30, respectively. Its stellar magnitude on June 15 is $-4·0$; the visible portion of the apparent disk increases from 0·379 to 0·555 during the month, and its distance from the Earth increases from 51 to 73 million miles. Mars is an evening star, but conditions for observation are becoming less favourable. It sets at 23h. 30m. on June 15. Jupiter rises at 23h. 40m., 22h. 45m. and 21h. 40m. on June 1, 15 and 30, respectively. It is in Capricornus; its stellar magnitude on June 15 is $-2·2$ and its distance from the Earth on that date is 400 million miles. Saturn rises at 23h. 20m., 22h. 20m. and 21h. 15m. at the beginning, middle and end of the month, respectively. It is near the border of Sagittarius and Capricornus; its stellar magnitude on June 15 is $+ 0·5$ and its distance from the Earth is 850 million miles. There is one occultation of a star brighter than magnitude 6 visible at Greenwich: June 3d. 1h. 42·2m., ρ Cap. reappearance. The summer solstice occurs on June 21d. 16h.

Announcements

Mr. M. J. Lighthill, director of the Royal Aircraft Establishment, Farnborough, has been awarded the Hopkins Prize of the Cambridge Philosophical Society for his contributions to fluid mechanics. The Prize has been awarded every three years since 1867 for work in mathematical-physical or related fields; the present award relates to the period 1957–60 and is of the value of £200.

Mr. Charles A. Marshall, editor of *British Communications and Electronics*, has been appointed honorary secretary of the Television Society in succession to Mr. Geoffrey Parr, who has been elected to an honorary life fellowship of the Society in recognition of his services during the past fifteen years. Mr. Parr will continue to edit the Society's *Journal*.

A summer school in quantum chemistry is being organized by Prof. C. A. Coulson and the Delegacy for Extra-mural Studies at St. Antony's College, University of Oxford, during September 9–23. Further information can be obtained from the Secretary, Extra-mural Delegacy, Rawley House, Wellington Square, Oxford.

The Institution of Engineering Inspection and the Society of Non-Destructive Examination are jointly organizing a conference at Oxford during September 5–8. Further information can be obtained from the Oxford Conference Secretariat, Institution of Engineering Inspection, 616 Grand Buildings, Trafalgar Square, London, W.C.2.

A conference is to be organized jointly by the University of Southampton and the Timber Development Association on "Timber Engineering", at the University of Southampton, during September 18–23. Further information can be obtained from Dr. H. G. Allen, Department of Civil Engineering, University of Southampton.

A symposium on North Atlantic biota and their history is being arranged under the sponsorship of the NATO Advanced Study Institutes Programme and will be held in Reykjavik during the first two weeks of August. Further information can be obtained from Dr. Áskell Löve, Institut Botanique de l'Université de Montréal, 4101 est, rue Sherbrooke, Montreal.

The Netherlands University Foundation for International Co-operation is organizing a summer school in science, which will be devoted to "Fundamental Problems in Statistical Mechanics", at Breukelen, The Netherlands, during August 1–16. Further information can be obtained from the Registrar, Netherlands University Foundation for International Co-operation, 27 Molenstraat, The Hague, The Netherlands.

A symposium on "Photomultiplier Tube Applications" is to be held at E.M.I. House, Manchester Square, London, W.1, during September 13–15. The symposium is being organized for the exchange of information on the application of photomultiplier tubes in a wide variety of scientific and industrial fields by E.M.I. Electronics, Ltd. A small nominal fee will be charged. Further information can be obtained from Mr. B. Johnson, Press Officer, E.M.I. Electronics, Ltd., Hayes, Middlesex.

A new series of publications, the *Annual Review of Astronomy and Astrophysics*, is being arranged by Annual Reviews, Inc., Palo Alto, California. The first volume will appear in the autumn of 1963, under the editorship of Dr. Leo Goldberg, Higgins professor of astronomy, Harvard University.

Translations into English of the Russian optics and spectroscopy journal, *Optika i Spektroskopiya*. have been arranged by the Optical Society of America. Special terms have been arranged for societies wishing to join the translation scheme and non-members and libraries. Further information can be obtained from the Assistant Secretary, OSA. 1155 16th Street, N.W., Washington 6, D.C.

Vol. 4, Part 5, of Scientific Institutions and Scientists in Latin America, issued by the United Nations Educational, Scientific and Cultural Organization, Montevideo, contains information received during the printing of the three former volumes, to which it is an appendix (Pp. i + 707–767. Montevideo : Unesco; Centro de Co-operacion cientifica para America Latina, 1960).

Hilger and Watts, Ltd., announce that Wray (Optical Works), Ltd., have come into association with them. Mr. A. W. Smith, a former president of the Scientific Instrument Manufacturers' Association, and chairman of its Education Committee, is continuing as managing director of Wray (Optical Works), Ltd.

MAN AND THE SOIL

A SYMPOSIUM, arranged jointly by the London Branches of the Institute of Biology, the Royal Institute of Chemistry, and the Institute of Physics and the Physical Society, was held on March 15 at the Senate House, University of London. The general title was "The Soil : Problems raised by its Use and Misuse", and the seven main speakers dealt with this question from the different points of view of biologists, chemists and physicists. Often a meeting of this kind, no matter how carefully planned, becomes in effect a series of unrelated papers. On this occasion the different contributions were clearly interrelated, and each contributed much to the understanding of the others.

The first speaker was Sir John Russell, who spoke on "Soil as Nature left it—Man's Use and Misuse". Sir John has, in an active working life as a soil scientist of more than sixty years, contributed more to our knowledge of the soil than any other person. He has always taken a broad view of the subject, and although he started as a chemist much of his work has elucidated problems of soil biology. On this occasion his paper did much to draw together the themes of the subsequent speakers. He showed how the equilibrium of a natural soil is upset by cultivation, and how a new equilibrium may be reached. Man may destroy the soil, but he may also prevent this destruction. Perhaps the most serious problem facing mankind to-day is whether research will be continued and applied in under-developed countries, now self-governing, so that the fertility of their soils can be maintained.

Mr. E. Crompton next spoke on "Soil Formation". He described the five soil-forming factors—parent material, climate, organisms, relief and time—and described how they combine to condition certain physical, chemical and biological processes occurring in the soil itself. The processes, which are the immediate mechanisms producing profile differentiation, he summarized as erosion/deposition, weathering, translocation and the organic cycle. These processes may produce many combinations, reflecting the geographical variety of the soil-forming factors.

"Physical Properties of Soil" was the title of the paper by Dr. H. L. Penman. He showed that soil physics has three aspects, for the emphasis of a technical problem may fall on the soil as a particulate system, as a porous system, or as a quasi-homogeneous system. Particle problems arise in weathering of soil, in clay mineralogy, in studies of soil structure. Pore-space problems are very important, for the biotic part of the soil needs living space, with water laid on, and some degree of air conditioning. In thermal studies, soil may be treated as homogeneous. However, ultimate explanations must go back to a study of particle properties, pore properties or both together.

Dr. G. W. Cooke spoke on "Some Chemical Aspects of Soil Fertility and Crop Production". He defined 'soil fertility' as the capacity of a soil to produce the crop desired. Fertility is not absolute, for a soil fertile enough to support a good forest may be so poor that farm crops fail on it. The term 'fertility' integrates physical and chemical factors that influence supplies of water, air and nutrients to roots; in addition, a fertile soil must anchor plants satisfactorily and be easy to cultivate and penetrate by roots. Chemical aspects of fertility are concerned mainly with nutrient supplies and reserves, but they also involve physical factors that affect root growth and penetration. The essential nutrients obtained from soil are calcium, potassium, magnesium, nitrogen, phosphorus and sulphur (the major nutrients) required in quantities of pounds or hundredweights per acre, and the much smaller quantities of micro-nutrients (from a few grams to a few ounces per acre are needed) boron, chlorine, cobalt, copper, iron, manganese, molybdenum and zinc. The rational use of different chemical fertilizers was indicated, and the importance of available or non-available reserves was discussed. Chemical analysis of soils, and the relation of the results to agriculture, is still a subject requiring much research.

The first primarily biological paper was on "The Interaction of Agricultural Practice and the Soil Fauna", by Dr. K. Mellanby. He stressed our ignorance of the soil fauna, and the difficulties in studying it. No complete census of the soil fauna of any field exists. Where soil animals are pests and destroy crops, these forms have been more thoroughly studied, and successful control measures devised, but the effects of these control measures on the rest of the fauna are unknown. Soil animals are believed to affect soil structure, the breakdown of organic matter and its incorporation in the soil, but few accurate quantitative data exist. Even earthworms, which often form more than 50 per cent of the total weight of the soil fauna, are animals the biology of which we still do not understand.

Dr. S. D. Garrett spoke on "Farming Patterns and Soil-borne Diseases of Crops". Crop rotation has, for centuries, been the main method of controlling soil-borne disease, as well as of controlling many insect pests and weeds. The efficacy of crop rotation depends on the host specialization of most parasites. Unfortunately many soil-borne diseases are caused by fungi with long-lived resting bodies, and so complete control requires rotations of undue length. 'Decoy crops' and other methods may eliminate some of the resting spores. Crop rotation alone cannot often eliminate a pest, but may keep parasite populations down to an acceptable level. Modifications of crop husbandry can prevent parasites from causing serious crop losses.

The last paper, by Mr. G. V. Jacks, was on "Climate and Erosion". He showed that four main factors determine the amount of man-accelerated soil erosion. These are land utilization, relief, erodibility of the soil, and the intensity of rain or force of wind. Land utilization is the only one of these factors controlled by man; it is also the most important, for natural erosion is generally important only in regions so arid that few crops could be grown. The importance of devising means of maintaining a complete plant cover in seasons when rain or wind would be likely to cause erosion was stressed. When this is done, the danger of erosion can be greatly decreased, and fertility restored in land already seriously affected by erosion.

KENNETH MELLANBY

SOLAR SEEING

WHILE the role of the atmosphere in degrading optical images has received considerable attention in respect of night-time observations, the question of day-time seeing has been almost completely ignored. In both cases temperature inhomogeneities cause the damage, though diurnal heating of the lower atmosphere results in conditions much worse by day than by night. Largely with the aim of stimulating interest in a subject of extreme importance to the selection of solar observatory sites and the design of solar telescopes, the Consiglio Nazionale delle Ricerche, with the co-operation of the Rassegna Internazionale Elettronica e Nucleare, organized a small symposium on "Solar Seeing" in Rome, during February 20–25.

In his opening address, Prof. M. G. J. Minnaert (Astronomical Observatory, Utrecht) differentiated between the blurring, dancing and scintillation (or intensity variation) of stellar images, and reviewed measurements of them. In general, there is little correlation between scintillation and blurring because the former results from the focusing effect of distant inhomogeneities only, whereas blurring and dancing can originate anywhere in the light path. The very few observations of stellar scintillation in the daytime have suggested that this is at most a factor of 1·5–2 stronger than at night, confirming its origin in the high atmosphere where changes due to diurnal heating are relatively small. Prof. Minnaert referred to the waviness of the limb on the solar image, pointing out that if the disturbed atmospheric layer is localized and if the direction of wave motion is parallel to the wind, a combination of the apparent velocity along the limb with that of shadows on the objective seen through a focal plane slit can give the layer height and velocity. As the subsequent controversial discussion demonstrated, a clear description of the phenomenon of limb waviness is as yet lacking, and its causes are still uncertain.

Prof. K. O. Kiepenheuer (Fraunhofer Institute, Freiburg) described seeing conditions at a wide number of sites in Europe. Wendelstein (1,840 m.), the highest mountain peak in its neighbourhood, has the best seeing conditions known in Germany, particularly with high-pressure systems, low wind velocities and snow-covered ground; but the total amount of sunshine is small. At Kanzelhöhe (1,560 m. and 1,900 m.), on a mountain covered with green woods, seeing is good only for a brief period in the morning, and possibly late afternoon, though it remains good longer at the greater height. Here, too, seeing is better in high-pressure conditions. At Zugspitze (3,000 m.), the seeing is good unless the wind is too strong. Freiburg, in the Rhine Valley, and Schauinsland (1,200 m.), nearby in the Black Forest, can differ greatly in seeing, but not preferentially. With easterly winds, seeing is bad presumably because the trees cause turbulence, while with westerly winds a turbulent 'Fern wind' descends from the Vosges mountains, causing bad seeing. However, very good seeing is again associated with high-pressure systems. At Lake Locarno (500 m.), the seeing improves continuously until early afternoon, being best when there is a general westerly wind, the nearby mountains funnelling it northwards over the Lake towards the observatory. Conditions deteriorate as the wind stops. At Anacapri (160 m.), seeing is good only in the morning and with winds from the sea, lasting longer in winter than in summer. With off-shore winds from the Apennine Mountains, seeing conditions are bad. In summary, Prof Kiepenheuer stated that sea breezes bring good seeing, siroccos bring bad seeing. In general, high-pressure systems are superior to low-pressure systems, presumably because with the former there is air slowly descending, while with the latter there is ascending air which has moved in over the heated ground. During summer, an increase of 10 m. in the height of the observatory above the ground can bring 2–3 more hours of good seeing.

Dr. G. E. Moreton (Lockheed Solar Observatory, Burbank), too, reported general correlations of seeing with meteorological conditions at the Lockheed Observatory. The Observatory (500 m.), open overhead and having a wooden floor with gaps, overhangs a hill and catches up-slope breezes. Definition is generally good with low inversion layers and poor with high inversion layers. At the Pic-du-Midi, Dr. J. Rösch (Observatoire du Pic-du-Midi, Bagnères-de-Bigorre) has found that good definition, though possibly with a little distortion, holds for an hour or so after sunrise. It is interesting that the time of optimum seeing differs for different instruments, clearly depending on the onset of turbulence associated with quite local heating. Miss Torelli (Rome Observatory) outlined observations of seeing conditions which indicate that in Rome image blurring is least in summer, though on the contrary the waviness of the limb is least in spring, late autumn and early winter. Finally, Dr. R. G. Giovanelli (Commonwealth Scientific and Industrial Research Organization, Sydney) described results obtained by Dr. Bray and Mr. Loughhead near Sydney. Recording limb-unsteadiness photoelectrically, they have found that on a day of good seeing there may be 50–200 occasions of good definition, each lasting a few seconds. In these, the limb steadiness first improves very rapidly (in a few seconds or even less than a second), and afterwards deteriorates to a more average value equally quickly; Dr. Priestley had suggested that this might possibly be correlated with a similar intermittancy in temperature fluctuations in the lower atmosphere, due to convective plumes, the rising air in which shows inhomogeneities of the order of 1 deg. C., the air between the plumes being uniform to better than 0·1 deg. C.

The design of solar telescopes to avoid internal seeing problems has interested a number of astronomers in recent years. Distinction may be made between long focal-length telescopes and short focal-length instruments where there is strong heating near the prime focus. In both cases, however, the height above the ground is important. Prof. D. H. Menzel (Harvard College Observatory) described the precautions being taken at the National Observatory, Kitt Peak, by water-jacketing the tower telescope so as to obtain homogeneous air in the long light-path within the instrument. As an aid to deciding the height of the tower, preliminary observations had been made on the temperature fluctuations at various heights in the atmosphere. Typically ΔT was approximately 2–3 deg. C. a foot or so above the ground, 1 deg. at 10 ft., 0·2 deg. at 55 ft. and 0·1 deg. at 180 ft., with a resolving time of about 1 sec., these results according with those of various micrometeorologists. A few preliminary observations made in Sydney of deviations produced in horizontal light beams at various heights were described by Dr. Giovanelli, the root mean square deviations falling off exponentially in the first 20 ft. with a scale-height of about 11 ft. These scanty results had been used to fix the height of the axis of the 5-in. equatorial photoheliograph at 9 ft. Mounted in the open, the use of air suction devices near all surfaces of this instrument exposed to direct sunlight, including the prime focus, seems to have eliminated completely any air inhomogeneities in or immediately outside the telescope.

Prof. Kiepenheuer showed a model of a new photoheliograph, to be made by Zeiss (Oberkochen), with the objective 10–14 m. from the ground. This instrument is also to be mounted in the open, but a special feature is a completely separate wind shield surrounding the telescope tube. To reduce heating, the supporting tower is to be faced with white tile, the heat reflectance of which is reputedly extremely high. A rather different approach to telescope design is the new Pic-du-Midi instrument, where Dr. J. Rösch has the telescope tube projecting well through the slit of a dome, the slit being sealed to prevent the mixing of internal and external air. Whatever be the relative merits of these various schemes, it is clear that, by bold but careful planning, considerable progress has been made in reducing or eliminating internal seeing problems. Moreover, it was welcome to hear from Prof. Menzel that proper thermal insulation of the large Sacramento Peak spectrograph had enabled it to yield definition as good as that of the vacuum spectrograph.

Whatever improvements are made, ground-based observations will almost certainly remain limited by atmospheric seeing conditions. Two devices to assist in the best use of moments of excellent seeing are the seeing monitor, which automatically selects these instants, and the electronic camera, which enables exposure times to be reduced so as to use them best. In Sydney, a seeing monitor operating on the steadiness of the solar limb has been used successfully by Dr. Bray and Mr. Loughhead to obtain, among other things, sequences of observations of facular granules; while a second device developed by Dr. Ramsay and Mr. Kobler is ready for field trials on stellar images, and with slight modification can be used for deciding movements of greatest granule contrast. Dr. Rösch has been experimenting with a somewhat similar device, recording the intensity fluctuations as a pinhole is scanned rapidly across the solar image; even at the best of times, successive scans show significant differences due to seeing.

Photographs have been obtained by Prof. G. Wlerick (Observatoire de Meudon, Paris) and Dr. Rösch and Mlle. Dupré on nuclear emulsions with a Lallemand electronic camera. The great speed (approximately 100 times that of normal photography) has already been used to obtain improved photographs of double stars and planets, while high-resolution solar spectra have been photographed in less than 0·1 sec. There is little doubt that, combined with a seeing monitor, the electronic camera will yield spectra showing the full angular resolution of the telescope.

A group of papers on meteorological aspects of turbulence left one with the feeling that the association between solar seeing and turbulence has been given much too little attention; the field is wide open for exploration. This was the general feeling of participants also, who at the final session passed the following resolution: "The members of the symposium are convinced of the necessity for more extensive research on seeing problems, particularly with the view of application to the selection of observatory sites; and therefore recommend that basic studies be made of the optical properties of the atmosphere". R. G. Giovanelli

TROPICAL ECOLOGY IN INDIA

A SYMPOSIUM on "Ecological Problems in the Tropics" was held at Allahabad during February 3–5, under the auspices of the National Academy of Sciences (India). The meetings were attended by more than one hundred scientists from all parts of the country. Dr. M. S. Randhawa, vice-president of the Indian Council of Agricultural Research, New Delhi, inaugurated the symposium and in his opening address specifically stressed the importance of ecological research in various development projects that the Government of India has taken in hand for the proper survey, development and exploitation of natural plant wealth of the country and for the increase in the production of food, fodder, fuel and fertilizers.

Dr. G. S. Puri, director of the Central Botanical Laboratory, Allahabad, who had organized the symposium, pointed out the progress so far made in Indian ecology and the need for a co-ordinated research programme in ecological studies in the tropics. He emphasized that the vegetation and animal life in the tropics raised problems entirely peculiar to these climatic conditions. He explained the concept of the forest ecosystem and recommended the use of *The Forest Ecosystem Proforma* published by the International Society for Tropical Ecology for use by the scientists in ecological studies and the application of the data to agriculture, forestry, soil and water conservation, desert immobilization, flood control, land use planning and wild life conservation, etc.

Forty-five papers were contributed to the symposium.

The paper by Sir Harry Champion on tropical ecological problems and by J. H. Davis were discussed with a number of those present. Prof. N. R. Dhar spoke on the value of nitrogen and phosphorus in Indian soils. Interesting papers were presented on the following subjects: tropical soils by Dr. G. S. Puri and K. Lakshminarayanan; fish ecology by Dr. S. M. Das and D. B. Saxena; arid zones by Sri S. K. Jain; relationships between habitat conditions and genome by Dr. R. P. Patil; distribution of perennial plants by Dr. J. K. Choudhury; soils of Madhya Pradesh by Dr. S. C. Pandeya; grasslands by Dr. S. S. Ramam; mangroves by Sri S. S. Sidhu; ecological problems in the Western Himalayas by Sri M. K. Wali; *Aspergilli* by Dr. B. S. Mehrotra; humid tropics by B. S. Ahuja and K. P. Singh; sal leaf litter by Sri N. K. Jain.

At the end of the symposium the following recommendations were made:

"Ecologists working on the tropical region, particularly Indian ecologists, should undertake co-operative studies to fill up the lacunæ in our knowledge as soon as possible. For achieving the purpose it is desirable to launch a vigorous and intensive programme of research with a view to obtaining data of practical and immediate applicability to agriculture, forestry and soil, water and wild life conservation. It is felt that *The Forest Ecosystem Proforma* prepared and published by the International Society for Tropical Ecology will be found of extensive utility. The same with a suitable amendment can be conveniently used for studies of animal and human ecology."

A committee to implement and expand the results of the symposium and to raise necessary funds needed for supporting the project in co-operation with the International Society for Tropical Ecology was formed. Further information concerning this project can be obtained from Dr. G. S. Puri, general secretary, International Society for Tropical Ecology, 10 Chatham Lines, Allahabad. *The Forest Ecosystem Proforma* can be obtained from the Society, price Rs. 5.

THE WEST AFRICAN RICE RESEARCH STATION

THE West African Rice Research Station, which is situated at Rokupr in Sierra Leone, is supported by the four West African territories of Nigeria, Ghana, Sierra Leone and Gambia. It is now ten years since a free grant from the United Kingdom under the Colonial Development and Welfare Act enabled the existing experimental station of the Sierra Leone Department of Agriculture to be transformed into a major inter-territorial research station, and five years since completion of buildings and establishment enabled a full-scale research programme to be started. It is hoped that this year will mark a further stage in development and that the Station will attain the status of an independent institute.

Rice production and consumption is expanding rapidly in West Africa, not only in Sierra Leone and adjacent parts where it has long been the staple food of the population but also in all other territories where it is of more recent cultivation. Present production in the whole of West Africa is estimated to be about one and a half million tons of paddy per annum, of which just more than a quarter of a million tons is produced in Sierra Leone. In view of the important part that rice seems destined to play in the economy of West Africa as a major food crop and in efficient utilization of the land, all Governments gave support to the establishment of the Station, the basic policy of which is to carry out fundamental research on rice as a crop under West African conditions, and to advise territorial Ministries, who remain responsible for local application and extension work, on their programmes of rice development and production.

The main station at Rokupr, in addition to an area of upland for administrative, laboratory and farm buildings and staff quarters and for experimental work on upland rices, consists of a 66-acre swamp rice-farm contiguous with the estuary of the Great Scarcies River, from which it is irrigated by tidal flooding with fresh water throughout the growing season. In addition, the Station maintains small areas on other types of soil in different parts of Sierra Leone. The laboratories, which were built in 1955, are well equipped and have recently been supplemented by a series of cabinets with controlled illumination and temperature for work on growth, an open-sided greenhouse for pot-work with soils and culture media, and a deep-water tank for experimental work with floating and flood-resistant rices. An air-conditioned building is provided for storage of the seed of the West African varietal collection, which is maintained by the Station, the responsibilities of which also include the maintenance of nucleus pure seed stocks of established and recommended varieties for seed multiplication schemes of the contributing territories.

At present the cultivation of rice in West Africa is carried out under a wide range of natural water conditions, from those of coastal mangrove swamps to the seasonal flooding of riverain plains in the lower-rainfall areas. There are extensive and widespread areas, potentially useful for rice growing, at present undeveloped. The attention of the Station has thus been concentrated on the investigation of the rice plant in relation to its habitat and on the production of rice varieties to suit natural conditions, together with work on soils and the changes that occur in them when modification of conditions may take place during development.

Selection from local and introduced varieties of rice has given excellent results in the improvement of yields in the past, but the stage has been reached when further advances can only result from a breeding programme which includes hybridization. The primary object of the present programme is the provision of high-yielding acceptable rice varieties for all the major West African habitats, including deep-flooding areas and rain-fed uplands. While consideration is given to factors such as disease-resistance, straw-strength and milling quality, none of these at present is of such importance as to warrant specific breeding programmes, and they are considered merely as they reflect on yield. Recent series of trials in various parts of West Africa indicate, however, that in some areas effects of light and, possibly, temperature are limiting in preventing existing established varieties from attaining their full potential, and a specific breeding programme for early maturing varieties insensitive to photoperiod is being undertaken. In conjunction, physiological investigations have been started on the effects of light and temperature on duration and yield.

Other physiological work to date has been largely designed to produce useful techniques for the plant breeders. Work on viability and dormancy has resulted in improved storage of seed and speeding up the breeding programme, while investigations into hydroponics and culture media have led to a method of clonal multiplication of considerable value in experimental use. Work on milling quality—in particular with the use of parboiling, the recommended and accepted method in West Africa—has indicated that modifications in established milling practice would probably increase the efficiency and output of the commercial mills to an appreciable extent.

Research on soils has been concentrated, during the past few years, on the chemistry and microbiology of mangrove soils; in particular, on the problems of their reclamation in areas where flood-waters are saline throughout the year. These soils, which are paralleled by vast areas of similar soils in many parts of the world, pose particular, problems due to their high content of sulphur and their potentiality for acid-development by microbial action on drying. Research work has now led to an understanding of the processes occurring in these soils and to the formulation of techniques of reclamation which are at present being tested in the field. More recently, attention has been paid to the changes in nutrient status of these soils—which are potentially highly fertile in their natural state—when they are reclaimed and cultivated.

Investigations are now being made into the relationship between the rice plant and soil conditions, in particular the oxidizing or reducing status of the soil and its poising by the balance of ferrous and ferric iron present. It is considered that this investigation will lead to useful techniques in the initial testing of soils for their suitability for rice growing, and for predicting the effect on them of specific modification of natural conditions.

Contributing Governments are kept informed of immediate practical recommendations, and an annual report of world-wide distribution is published to record briefly the work in progress; individual researches are reported more fully by contributions to technical journals. It is of note that within ten years of its inception the Station has been able not only to play its part in the general economic development of West Africa but also to contribute substantially to scientific knowledge of the world's major food crop.

H. D. JORDAN

TECHNICAL EDUCATION IN WALES

A RECENT report dealing with technical education in Wales* is as surprising for the boldness of its recommendations for training within industry as it is for its ambivalence about the resolution of educational and administrative problems within its purview. Within a brief sixty pages it first reviews the history of technical education in Wales with candid admissions of former shortcomings, then it surveys the great changes in industrial background. The present pattern of technical education is next reviewed, under three main headings, of courses and training for craft apprentices, student apprentices and graduate apprentices. Significant differences are noted from the rest of the British scene. In this way the report rapidly traverses the background to its terms of reference, which were "In the light of contemporary changes in the industrial pattern in Wales, to consider what educational provisions should be made to serve the best interests of industry and of those employed in it."

The fourth and final chapter of the report of the Central Advisory Council for Education (Wales) embodies the Council's observations and recommendations, some of which go well beyond the particular needs and circumstances of Wales. The report incorporates much contemporary discussion and exhortation, and thus joins in the now customary commendation of such developments as block-release courses, sandwich courses, pre-apprenticeship courses, group apprenticeship training schemes, a two-year Ordinary National Certificate course, the introduction of lower standard courses for new City and Guilds of London Institute examinations, and other ideas to be found in the Crowther Report and the second White Paper *Better Opportunities in Technical Education.*

A fundamentally new approach for industrial training in the United Kingdom is urged in the proposed establishment of a national craft apprenticeship system, especially to meet the needs of small firms which largely compose British industry, particularly in Wales. This would be administered by the State through the Ministry of Education and a National Apprenticeship Council, training being given from the age of sixteen years in apprentice training centres. The centres may or may not be attached to technical colleges, and would be financed by an apprenticeship levy on industry (though curiously this important point is not mentioned in the final summary of recommendations). This proposal constitutes a strong challenge to present Government policy, and to the existing Industrial Training Council; but the report sees no other adequate way of meeting the compelling needs of the greatly increased age-groups 16–19 years coming into industry from 1963 onwards, or of meeting the needs of smaller firms.

With regard to advanced courses, the report concludes that the overall provision greatly outruns the present demand, and urges that to avoid wasteful and inefficient duplication these courses should be confined to five technical colleges—Treforest, Newport, Swansea, Wrexham, *together with* the Welsh College of Advanced Technology in Cardiff. The words here shown in italics illustrate the Council's refusal to grasp the essential ideas of the four-tier structure of technical education, with preferential concentration of advanced courses in the colleges of advanced technology. This is related to its somewhat despairing view of the continued existence of the Cardiff College, of which it presents a very partial picture indeed (it has 186 in sandwich courses within four years of its designation out of a total sandwich course *and* full-time enrolment—not mentioned—of 826 students—compared with 732 students at the University College of North Staffordshire after 10 years of existence, not to mention the former's large part-time enrolment).

The report suggests that all five colleges should be administered jointly by an administrative council which might be the technical sub-committee of the Welsh Joint Education Committee. Never was there a better example of the new Benthamism—the greatest pacification of the greatest number of local education authorities, and consequently, the strongest possible built-in deterrent to the emergence of concentrated excellence at the College of Advanced Technology. Not surprisingly, the Council concludes that the proposal to seek closer association of the latter college with the University is not inconsistent with the purposes of the University. So little does it regard the Welsh Advanced College in its own right, that it sees the link with the University as unquestionably conferring status on technical studies in Wales, and that "A further and quite substantial advantage would be that a clearer and more easily recognisable line of demarcation than now exists could be drawn between the College of Advanced Technology and other technical colleges concerned with advanced courses". Under the Administrative Council, or under University governance, or both? What happens then to the new route in higher education complementary to that of the universities, and to the apex of the technical college system?

---

* Ministry of Education: Central Advisory Council for Education (Wales). *Technical Education in Wales.* Pp. ix + 146. (In English and Welsh.) (London: H.M. Stationery Office, 1961.) 7*s*. net.

Instead of being doubled in size through bilingual publication, the report would have been better had it analysed more fully the consequences of its recommendations, and also dealt with some important omissions. Notable among the latter are some of the basic reasons why less than 2 per cent of eligible Ordinary National Certificate candidates go on to courses for the Diploma in Technology, and less than 7 per cent to Higher National Diploma courses. Do the other colleges accept a contributory role to the higher colleges? The resistance to change and support of new ventures, for example, by the schools and firms, are hinted at but not fully examined. Nowhere does the report deal candidly with the issues underlying "the delicate work of regionalisation of advanced courses . . ." which as an independent body it ought to have done; it is not surprising already to find it reported that the Flintshire authorities are taking steps to protect their right to advanced courses. A more penetrating and critical examination on the educational and administrative sides, as was done on the apprenticeship side, would have greatly increased the value of the report. The Minister of Education commends the report as a good one, and hopes that many of the recommendations will be put into practice as soon as possible: many, it may reasonably be hoped, but not some of its major ones, not at all before due consideration has been given to the report of the Committee of Enquiry into Higher Education, of which Lord Robbins is chairman.

P. F. R. VENABLES

ADDICTION-PRODUCING DRUGS

IN the eleventh report issued by the World Health Organization's Expert Committee on Addiction-producing Drugs* recommendations are given that the following substances should be subject to the provisions of the 1931 Convention in respect of addiction-producing drugs comparable to morphine: clonitazene, diapromide, diphenoxylate, etonitazene, hydromophinal, phenampromide and phenoperidine.

Evidence concerned with two analgesic benzodioxane derivatives and ethoheptazine indicated that these compounds were not to be regarded as addiction-producing drugs. Exemption from the provisions of international control was recommended in favour of two preparations containing diphenoxylate, a new constipating agent, but the Committee was unable to support the request for exemption in favour of dextro-phenomorphan.

The Committee was concerned with reports on the abuse of amphetamines and amphetamine-like substances contained in weight-reducing medicines, and emphasized the need for appropriate control measures on a national level to prevent such abuse. Attention was also directed to the need to watch closely the development of new psychically active compounds that might be abused by narcotic addicts, as has already occurred in the case of SPA((−)-1-dimethylamino-1,2-diphenylethane) in Japan. There is need for improvement in regard to the information given on the possibilities of addiction liability of new drugs, particularly where analgesic and anti-cough properties are claimed.

In response to an invitation from the Economic and Social Council, the Committee outlined the procedure by which the addiction-producing properties of a drug are established; but a precise code of practices cannot be drawn up at the present time.

The Committee was not of the opinion that there is at present any case for making *Cannabis* available for the extraction of antibiotic substances, and considered that the prohibition or restriction of the medical use of this plant should continue to be recommended by the international organs concerned.

With regard to the treatment of drug addicts, the Committee was in favour of a proposal that addicts should be committed to the care of a medical panel, as is done in the case of mental patients in general. This measure is intended to ensure adequate and complete treatment, but not to replace penalties for violations of the law.

CULTURAL SEQUENCES IN NORTH-WEST AMERICA

IN the past few years, evidence has been accumulating for a considerable variety in subsistence activities at an early date in North America. To the big-game hunters of the Plains have been added people who gathered seeds and plants and hunted small game in the Great Basin, and the archaic foragers of the East have proved to have begun earlier than we used to believe. The latest report* of Prof. L. S. Cressman's pioneer explorations in the north-western United States shows that yet another way of life was followed by people who settled at the strategic point where the Columbia River passes through the Cascade Range on its westward journey. In historic times this was a great trading centre and the Indian inhabitants were noted middle-men.

Trans. Amer. Phil. Soc.*, N.S., **50, Part 10: *Cultural Sequences at the Dalles, Oregon—a Contribution to Pacific Northwest Prehistory.* By Prof. L. S. Cressman, in collaboration with David L. Cole, Wilbur A. Davis, Thomas M. Newman and Daniel J. Scheans. Pp. 108. (Philadelphia: American Philosophical Society, 1960.) 3 dollars.

The construction of the Dalles Dam was the occasion of an archæological salvage programme, and Prof. Cressman, of the University of Oregon, undertook the work on the left bank of the river. A good deal of the evidence had been destroyed by previous building work, but Cressman succeeded in establishing a continuous succession from at least 8000 B.C. to recent times. (The date is based on a composite radiocarbon sample from the lowest stratum, and Cressman considers that it could indicate a beginning date of 9000 B.C. or earlier.) At an unknown time before this, the release of some 500 cubic miles of water by the breaking of an ice dam had produced a fantastic flood through the gorge, obliterating most of the signs which could indicate an earlier occupation, although Cressman produces some rather slender evidence that there might have been one.

The succession falls into three main divisions, dated by four carbon dates. There is an early one lasting until a few centuries after 6000 B.C., followed by a transition lasting to about 4000 B.C., leading to a late period covering protohistoric and historic times. Certain types of artefact are confined to the early period and others to the late, and there are two other groups, one of which decreases from an early maximum while the other increases to a late one. The period of greatest interest to readers outside North America is the early one, to which antler and bone artefacts, bolas stones, certain types of projectile point, and burins are confined. The assemblage is interpreted as indicating a great exploitation of the salmon run, the hunting of large scavenger birds (the condor, etc.) with the bolas, and the hunting of small animals and, to a lesser extent, elk and deer; in short a dependence on the river and its immediate surroundings. Of great interest is the use of burins to cut antler and bone, in exactly the same way as was done at Prof. Grahame Clark's Mesolithic site at Star Carr in Yorkshire at about the same time, though many of the resulting artefacts differ. With the end of the early period not only the characteristic artefacts but also the animal, bird and fish bones disappeared entirely from the archæological record, a loss which has not yet been satisfactorily explained.

G. H. S. BUSHNELL

TOTAL MAGNETIC FIELD MEASUREMENTS BETWEEN NEW ZEALAND AND ANTARCTICA

By DR. D. A. CHRISTOFFEL

Geophysics Laboratory, University of British Columbia, Vancouver

SOME results of a survey of the Earth's total magnetic field between New Zealand and Antarctica are presented in this article. No magnetic survey of this area has previously been made.

A proton magnetometer, of design similar to that described by Hill[1], was constructed at the Naval Research Laboratory, Auckland, New Zealand. It was installed aboard the Antarctic supply ship, H.M.N.Z.S. *Endeavour*, and was operated during this ship's Antarctic cruise between December 20, 1958, and February 15, 1959. One measurement was made each minute and the readings were recorded on a strip chart recorder to a significant value of 1γ.

Figs. 1 and 2 show charts of the area covered by the operation. The solid portions of the ship's track represent those parts over which measurements were obtained. The decimal figures beside the tracks give the values of the total field in gauss. These values have been smoothed, where necessary, to correct for local anomalies, but no corrections for time variations of the field have been made. The solid line contours have been drawn both from these measurements and also by reference to spot values obtained for various islands in the area and from the New Zealand Geomagnetic Survey maps[2]. The dotted line contours are from a total field chart issued by the U.S. Hydrographic Office, 1955 (ref. 3). It will be seen that south of lat. 55° S. the two sets of values diverge considerably. In particular, at lat. 61° S., long. 172° E., where the 1955 data show a maximum of 72,000γ, the value measured in the present instance was only 66,000γ. This discrepancy continues over the area of the Ross Sea shown in Fig. 2. Three isolated values which have been obtained from extrapolated rocket flight measurements[4] are shown in Figs. 1 and 2 with the values that were recorded marked beside them. It will be seen that these values agree with the measurements made in the present survey. Extrapolation of the field-values from the contours show that the maximum of 72,000γ would be located near a position lat. 70° S., long. 150° E.

In Fig. 3 two profiles of the total field which were obtained across an ocean trough are given. This trough is bounded to the north by a line of islands passing through Auckland, Campbell, Bounty and the Antipodes Islands, and the tracks cross it at a latitude of approximately 54° S. To the south the ocean trough is bounded by a portion of the mid-ocean ridge system. This section appears to run from just north of the Balleny Islands to Easter Island and the ship's tracks cross it at a latitude of approximately 68° S. The bathymetric depth over most of the 600 miles of the tracks shown in Fig. 3 was between 2,800 and 3,000 fathoms, and so far as could be ascertained from the depth measurement was flat. These depths were determined from explosive echo soundings made during the transit and from Admiralty Chart 788 and U.S.N. Hydrographic Office Chart No. 6636. The trough runs in a direction N. 74° E.

It will be seen that the peaks of anomaly have amplitudes of between 200 and 500γ, and that at least 25 of these may be correlated between the two

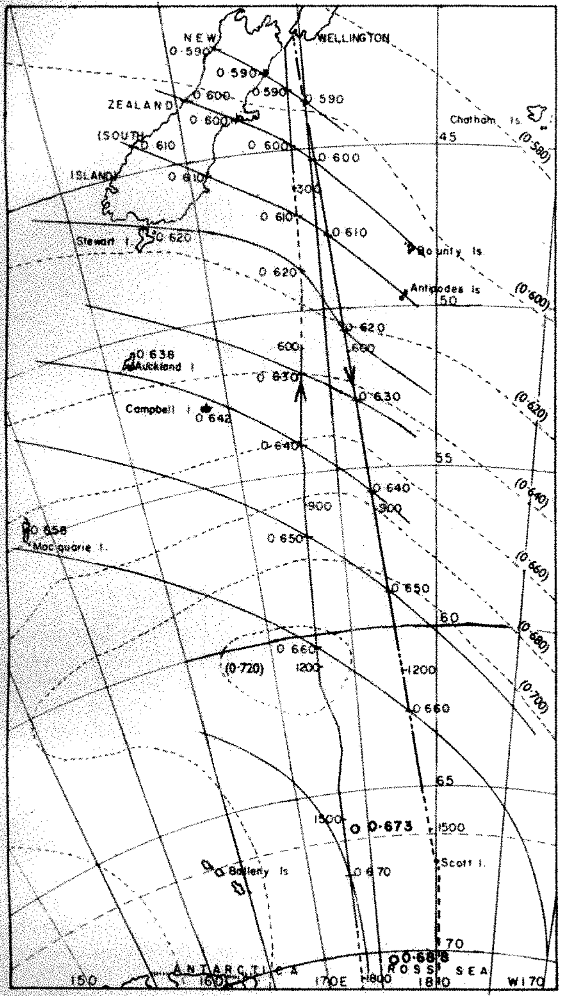

Fig. 1. Smoothed values of total-force magnetic field between Wellington, New Zealand, and Cape Adare, Antarctica
——, Contours extrapolated from values measured on present survey, and from stations in the area. Values in large numerals. – – –, Contours from U.S. Hydrographic Office, 1955 (values in parenthesis)

tracks in the 600 miles shown. The correlated lines are closely parallel to the direction of the bathymetric trough.

The anomalies are generally characterized by steep sides with, in some cases, flattened peaks. On the assumption that these are produced by dykes of magnetic material the thickness of which is comparable with the depth of the ocean, depth and susceptibility calculations have been made using the methods outlined by Henderson and Zietz[5]. It is found that in all cases the depth to the material producing the anomalies lies between 3,000 and 4,000 fathoms below sea-level, that is, only a short distance below the sea bottom. The contrast of susceptibility of the material is between 0·6 and $1·6 \times 10^{-3}$ c.g.s. units and increases uniformly towards the south.

These anomalies bear a remarkable resemblance to those found in the comprehensive surveys conducted off the Californian Coast by the Scripps Institution of Oceanography[6]. In each case, the anomalies have similar amplitude and shape. They are found to occur on essentially flat ocean floors and do not correspond to bathymetric contours. The susceptibilities needed to produce the anomalies are high, indicating that the rocks must be of basic igneous origin.

An explanation advanced by Mason[6] is that these anomalies are produced by comparatively shallow

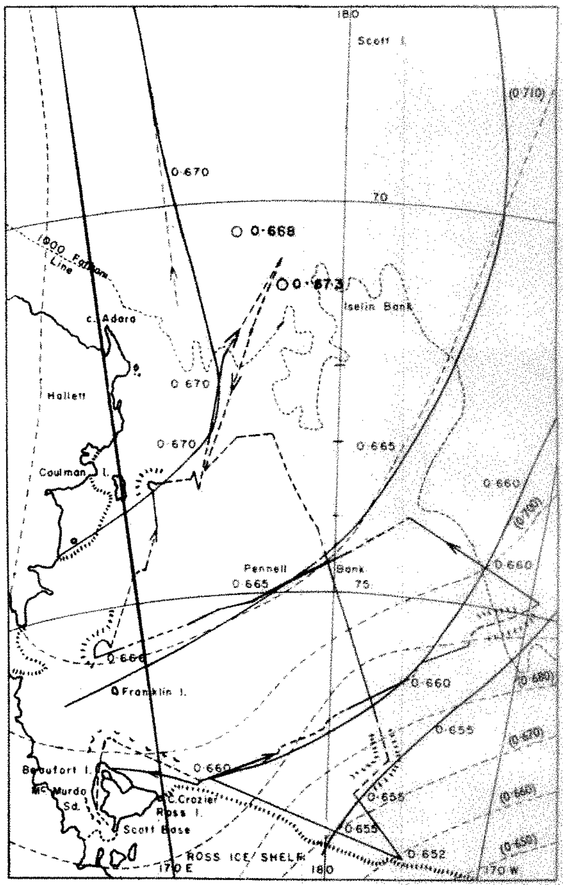

Fig. 2. Smoothed values of total-force magnetic field, Ross Sea, Antarctica

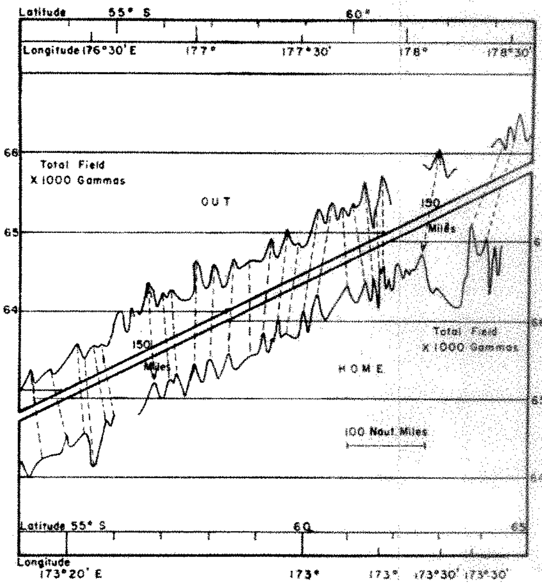

Fig. 3. Correlation, over 600 miles of track, between total field-measurements made on outward and homeward runs

lava flows which have spread out over the floor of the ocean. However, this does not explain why they should flow in parallel streams. It will be noticed that the anomalies off the Californian coast run approximately north and south, that is, parallel to the active primary mountain arc which extends down the west coast of America. In the present case the anomaly lines are parallel to the island arc in the north and the mid-ocean ridge to the south. An alternative explanation might be that, owing to the thrusts from either side, the sub-oceanic basalt layer has been buckled downwards, and fissures normal to the thrust direction have opened up, thus permitting the intrusion of lavas from beneath. This would explain both the nature and direction of the observed anomalies.

This work was part of a scientific programme undertaken by the Naval Research Laboratory, Auckland, New Zealand, and was carried out while I was in the New Zealand Defence Scientific Corps.

STAGNATION TEMPERATURE MEASUREMENTS IN A HYPERSONIC WIND-TUNNEL USING THE SODIUM LINE REVERSAL METHOD

By J. L. STOLLERY

Aeronautics Department, Imperial College of Science and Technology, London

THE sodium line reversal method[1] has recently been used to measure transient temperatures between 1,400° K. and 3,000° K.[2,3]. In the gun tunnel[4], stagnation temperatures in this range can be generated. Measurements were made in the tunnel working section by examining the flow between a blunt body and its bow shock-wave. The gas temperature in this zone is close to the stagnation value.

The experimental arrangement is described fully in ref. 5. The blunt body finally used was a 1¾-in. diameter disk. Originally, a thin layer of common salt was stuck to the front face of the model by moistening the surface. During the test period a 'cloud' of salt particles was 'liberated', interrupted the light beam and gave a false signal of absorption. Since far too much salt was introduced by this first method, the salt was powdered next and rubbed dry on the model surface. This proved to be both simple and effective.

The first tests were made with the background light source switched off. The flow around the model was viewed with the naked eye, as well as being recorded by the photomultiplier tube and oscilloscope. When the stagnation temperature was sufficiently high for useful measurements to be made, a yellow glow within the stand-off distance was clearly visible. It was soon obvious that at the large pressure ratios needed to generate measurable temperatures, the existing piston design was inadequate. Fig 1 shows a trace indicating emission throughout the 30-m.sec. running time but the dural piston body was deformed and the nylon skirt broke and burnt completely, so increasing the test-gas temperature.

During thirty-five runs various piston materials, designs and operating conditions were tried. Finally, an all-dural design generated measurable temperatures and lasted for about ten runs before structural failure. Fig. 2 shows a typical trace with a background source temperature of 1,510° K. Reading left to right at 5 m.sec./cm. it is apparent that 5 m.sec. after the oscilloscope is triggered there is an abrupt emission signal followed immediately by 2 m.sec. of absorption. These initial changes are thought to correspond to piston overshoot followed by piston reversal. The rest of the trace shows absorption, indicating that the gas temperature was less than 1,510° K. Sufficient runs were made to

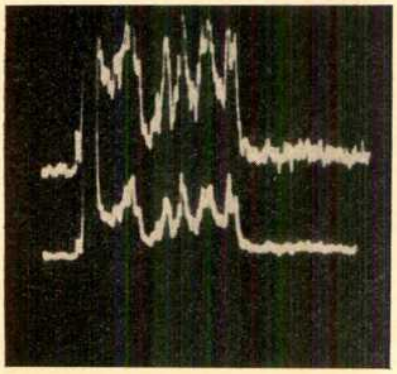

Fig. 1. $P_4 = 2{,}515$ lb./in.^{2} absolute; $P_1 = 5$ lb./in.^{2} absolute; $P_4/P_1 = 503$ (trace 17)

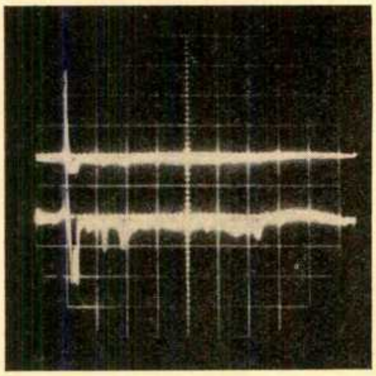

Fig. 2. $P_4 = 3{,}015$ lb./in.^{2} absolute; $P_1 = 7{\cdot}4$ lb./in.^{2} absolute; $P_4/P_1 = 407$; delay, 8·7 m.sec.; source temperature = 1,510° K. (trace 88)

bracket the air stagnation temperatures generated under three operating conditions, namely :

P_4 (lb./in.^{2} absolute	P_1 (lb./in.^{2} absolute)	Damping plate
3,000	7·4	In
3,000	7·4	Out
3,000	10	Out

Though the temperatures measured were accurate to within ± 15° K., there are various corrections to be applied, the most serious of which is due to real gas effects. The sodium line reversal method measures the sodium electronic excitation temperature which, for a diatomic gas, 'follows' the vibrational temperature of the gas extremely closely[3]. If the gas is not in thermal equilibrium, the (vibrational) temperature measured will not be the true stagnation value. Gaydon and Hurle[6] have shown that the vibrational relaxation time for air is comparatively large and increases rapidly as pressure and temperature fall. This means that the nozzle flow will not be in vibrational equilibrium, and that the vibrational temperature will be much higher than the true (translational) flow temperature in the test-jet. On passing through the bow shock-wave, the air is heated again and the situation is reversed. There is insufficient time for the gas vibrational temperature to rise to the true stagnation value though the 'error' is now reasonably small due to the non-equilibrium in the test jet. Preliminary calculations indicate that the temperature measured is about 250° K. below the stagnation equilibrium value. Other corrections allowing for: (1) the effects of longitudinal and transverse temperature gradients ; (2) heat transfer to the disk, are discussed in ref. 5. All the corrections cause the sodium line reversal method to read low. The total correction is estimated to be 350° K.

The results are plotted in Fig. 3 and compared with : (*a*) the idealized estimated values; (*b*) isentropic compression; (*c*) the temperature behind a single reflected shock-wave; (*d*) other experimental data[7] the accuracy of which is ± 100° K. The comparison shows that the gun tunnel is generating temperatures in excess of the isentropic and reflected shock-values, but considerably below the perfect gas idealized estimates. What it does not show is the probable limit on P_4/P_1 of around 500 due solely to the mechanical strength of the piston. It seems likely that to generate temperatures above 2,000° K., wave-heating (zero piston-mass) will be the only solution.

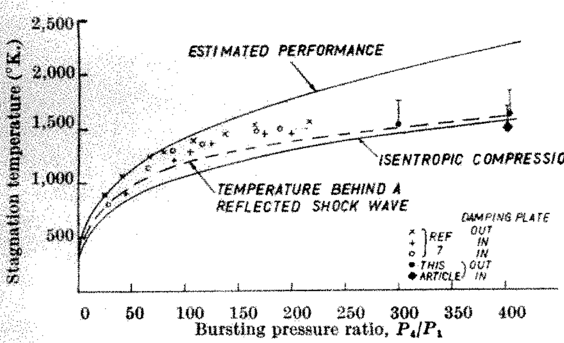

Fig. 3. Gun tunnel temperature measurements

The measured temperatures agree with the trend suggested by the A.R.D.E. experiments[7] and the measured temperature increase that results from removal of the damping plate is similar to that found by A.R.D.E.[7].

Conclusions : (1) Unless a dramatic improvement in piston design is made, enabling a very light, non-inflammable and extremely strong piston to be manufactured, the reservoir temperatures generated in the gun tunnel will be limited to 2,000° K. (2) Removal of the damping plate increases the stagnation temperature for a given bursting-pressure ratio. It also changes the reservoir pressure history to a castellated form, the first step of which has a magnitude which is greater than the bursting pressure, and a duration of nearly 20 m.sec. It would therefore seem sensible to use this period as the effective testing time and operate the tunnel with the damping plate out. (3) Since most traces showed either emission or absorption for the whole of the steady running time of 30 m.sec., and since the type of signal was changed by a 30° increase in source temperature, it is probable that the rate of temperature loss was less than 1,000 deg. K./sec.

This work was done during a visit to the National Research Council, Ottawa, Canada. The co-operative attitude and generous help of W. F. Campbell, R. Meyer and the tunnel technicians is most gratefully acknowledged.

FORMATION OF HELICAL MICROFIBRILS FROM A STEROID ACID COMPLEX

By Dr. N. RAMANATHAN*, A. L. CURRIE† and J. ROSS COLVIN

Division of Applied Biology, National Research Council, Ottawa

THE demonstrated helical molecular structure of many biological polymers has led to the suggestion that super-helices may be formed from the initial coils and may be resolved in the electron microscope[1]. The idea is plausible and important since it provides a bridge between molecular chains and microscopic fibres, but definitive examples of its application are few in number. One example is the observation of a super-helical form in starch[2] and a second is the recent report of helical strands in sodium deoxycholate suspensions[3], which are helical at the molecular level[4]. We report here two additional properties of these helical strands and the results of an extension of observations to six related bile acids. The spontaneous association of deoxycholic acid to form coils at both the 10 Å. and 100 Å. level is of particular interest since no polymerization of the substance takes place[4].

---

* N.R.C. Postdoctoral Fellow, 1958–59. Present address: Central Leather Research Institute, Madras, India.

† N.R.C. Postdoctoral Fellow, 1958–60.

The morphology of aggregates of seven related bile acids was examined by the electron microscope. Deoxycholic, cholic, apocholic, lithocholic, hyodeoxycholic and glycocholic acids were precipitated by hydrochloric acid from their sodium salts, washed with water, and recrystallized from aqueous ethanol. Taurocholic acid was prepared from its sodium salt with hydrochloric acid, precipitated by ethanol and washed thoroughly with ethanol. All acids except taurocholic were dissolved in ethanol and added dropwise to de-ionized water or an appropriate buffer, until a slightly cloudy suspension was obtained. Taurocholic acid was added directly to water. Preparations without buffer were dried directly on grids covered with a carbon film. Preparations in buffers were dialysed overnight on 'Formvar' films floating on water. After mounting on grids and drying, all specimens were shadowed at an angle of 15° with gold–palladium (60–40).

Of the above bile acids, only deoxycholic formed helical microfibrils when suspended in de-ionized water at pH 5 or in phosphate buffers up to pH 7·4 (Fig. 1). Above pH 7·4, no microfibrils were detectable. When water suspensions of deoxycholic acid were dried on carbon films after zero, two, four or eight hours standing, the form of the helical microfibrils changed progressively to rod-shaped aggregates (Fig. 2). After 8 hr., the super-helices had almost disappeared.

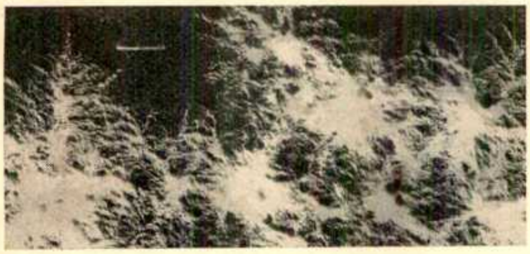

Fig. 1. Helical microfibrils of deoxycholic acid suspended in water and dried immediately

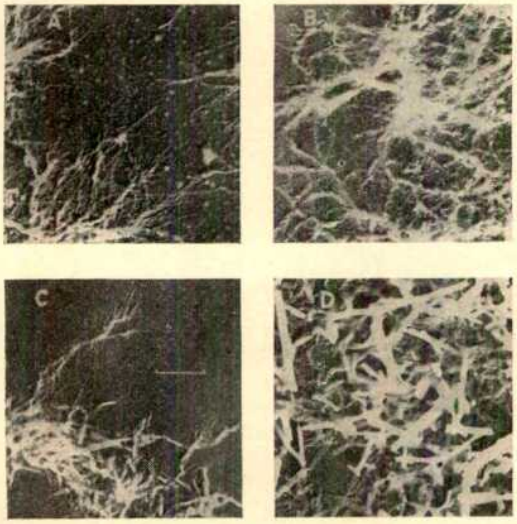

Fig. 2. Microfibrils of deoxycholic acid formed after standing for: *A*, 0 hr.; *B*, 2 hr.; *C*, 4 hr.; *D*, 8 hr.; all of equal magnification

A further property of all preparations of helical microfibrils from deoxycholic acid was a right-handed twist, presumably reflecting a characteristic asymmetry of the form of the molecule (Fig. 1). This asymmetry is not an artefact of the conditions of preparation for comparative preparations of helical microfibrils from potassium palmitate[5] consist of both left- and right-handed helices in approximately equal numbers (Fig. 3).

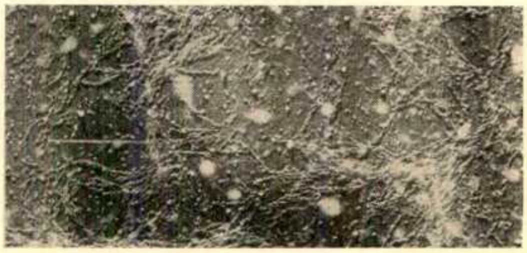

Fig. 3. Microfibrils of potassium palmitate

Deoxycholic acid fibres drawn from a solution buffered with glycylglycine gave an X-ray diffraction pattern identical with that reported previously[4]. When these fibres were dispersed in water on carbon-covered grids, they also showed typical helical microfibrillar substructure.

Of the remaining acids, only lithocholic formed aggregates which showed as bundles of straight microfibrils (Fig. 4).

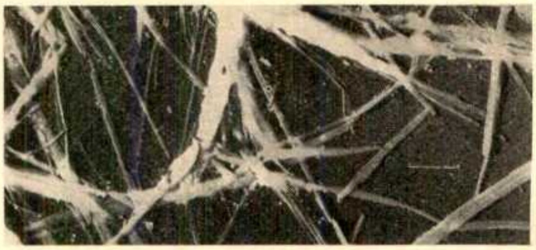

Fig. 4. Lithocholic acid bundles

The present observations, coupled with those of others[3,4], illustrate a particular example of a class of systems analysed by Pauling in qualitative terms, which are of interest in themselves and which may afford a model for some cases of biological fibrogenesis[1]. The asymmetric, un-ionized deoxycholic acid molecules in aqueous solution quickly and spontaneously pack together under the influences of London dispersion forces to form extended linear molecular helices, which are reflected in a high viscosity and the capacity to form brittle, crystalline drawn fibres. Small systematic deviations in the regularity of stacking of the steroid groups cause the molecular helices themselves to have a screw-form, leading to characteristic helical microfibrils or bundles of such microfibrils. Above neutrality, the association of the un-ionized bile-acid molecules is progressively destroyed by Coulomb repulsion of the carboxyl groups. Minor variations of molecular structure (that is, introduction of a double bond in the 8–14 position of deoxycholic acid to give apocholic acid) may eliminate the close packing necessary to give microfibrils or the asymmetry required for a helix (for example, lithocholic acid which is deoxycholic lacking only the hydroxyl group at C_{12}). As might be expected, helical microfibrils are appreciably stronger than straight aggregates since lithocholic acid forms no detectable complexes comparable to those of deoxycholic[4], although it does form straight rods of a comparable size. However, why the packing of the molecular helices in the microfibrils is only metastable with respect to the straight form is not yet clear.

THE ACTIVE SITE AND MECHANISM OF ACTION OF BOVINE PANCREATIC RIBONUCLEASE

By DOROTHY FINDLAY, D. G. HERRIES, DR. A. P. MATHIAS, DR. B. R. RABIN and C. A. ROSS
Department of Biochemistry, University College, London

BOVINE pancreatic ribonuclease (RNase) is the only enzyme the primary structure of which is known[1]. A great deal of work has been done on the secondary and tertiary structure of this protein, but it is not possible to make any definite formulation of the conformation in aqueous solution[2]. In fact, several catalytically active, but physically different conformations can be produced[3]. Richards[4] has shown that subtilisin hydrolyses RNase between amino-acid residues 20 and 21 (numbering from N-terminal) without loss of activity. The peptide of 20 amino-acid residues (S-peptide) remains attached to the protein moiety, from which it may be separated by fractionation with trichloroacetic acid. The enzyme may be reconstituted, with full catalytic activity, by mixing the two fragments in aqueous solution.

RNase has four histidine residues at positions 16, 48, 105 and 119. Weil and Seibles[5], on the basis of photo-oxidation investigations, suggested that one or more of these histidine residues was associated with the active site. Histidine residue 119 reacts with iodoacetate or bromoacetate, with loss of catalytic activity[6], far more readily than the others at *p*H values between 5 and 6. Vithayathil and Richards[7] have shown that histidine 16 of modified S-peptide may be alkylated with iodoacetate with no loss of activity in the reconstituted enzyme. We have accumulated evidence in this laboratory[8] that two histidine residues are probably involved at the catalytic site of RNase and this, together with other data, has been used to formulate a mechanism of action of this enzyme.

Detailed investigation of the *p*H-activity curve of the hydrolysis of cytidine 2′ : 3′-phosphate has shown that the reaction can be interpreted in terms of the following scheme:

$$\begin{tikzcd}
EH_2 \arrow[r, phantom, "\overset{K_b}{\rightleftharpoons}"] & EH \arrow[r, phantom, "\overset{K_a}{\rightleftharpoons}"] \arrow[d, phantom, "\upharpoonleft\downharpoonright"] & E \\
EH_2S \arrow[r, phantom, "\overset{K_{b'}}{\rightleftharpoons}"] & EHS \arrow[r, phantom, "\overset{K_{a'}}{\rightleftharpoons}"] \arrow[d] & ES \\
& \text{products} &
\end{tikzcd}$$

S represents the substrate; EH_2, EH and E represent the enzyme at different stages of ionization; charges are not specified. The constants are defined thus:

$$K_b = \frac{[EH][H]}{[EH_2]} \qquad K_a = \frac{[E][H]}{[EH]}$$

$$K_{b'} = \frac{[EHS][H]}{[EH_2S]} \qquad K_{a'} = \frac{[ES][H]}{[EHS]}$$

At any single *p*H the initial velocity can be fitted accurately to the Michaelis equation:

$$V = \frac{k_3 \cdot [E_0][S]}{K_m + [S]} \tag{1}$$

where E_0 is the total enzyme concentration. The variation of the parameters of equation (1) with *p*H is shown in Fig. 1. The results fit the following expressions:

$$k_3 = \frac{\bar{k}_3}{1 + \frac{[H]}{K_{b'}} + \frac{K_{a'}}{[H]}} \tag{2}$$

$$K_m = \frac{\bar{K}_m\left(1 + \frac{[H]}{K_b} + \frac{K_a}{[H]}\right)}{\left(1 + \frac{[H]}{K_{b'}} + \frac{K_{a'}}{[H]}\right)} \tag{3}$$

where $\bar{k}_3$ and $\bar{K}_m$ are constants independent of *p*H. The values obtained for the constants are shown in Table 1. Serious reservations have to be made in interpreting results such as these[9], though, as a first approximation, it is permissible to identify the acid dissociation constants of equations (2) and (3) with those of the reaction scheme. The values of K_b and K_a suggest that both are dissociations from imidazole groups of histidine residues. One of these is required in the base form and the other in the acid form for catalytic activity. The measured constants are 'macroscopic'[10]; but, because of their relatively large separation, they probably do not differ greatly from the intrinsic *pK* values of the acid and base sites.

Table 1. *pK* VALUES OF THE GROUPS AT THE ACTIVE SITE OF RIBONUCLEASE OBTAINED FROM THE KINETICS OF THE HYDROLYSIS OF CYTIDINE 2′: 3′-PHOSPHATE AT IONIC STRENGTH 0·2 AND 25° C.

Free enzyme	Enzyme-substrate complex
$pK_b = 5{\cdot}22$	$pK_{b'} = 6{\cdot}30$
$pK_a = 6{\cdot}78$	$pK_{a'} = 8{\cdot}10$

If there were two groups on the enzyme, one an acid, the other base, which bind the substrate, the formation of the enzyme-substrate complex would result in lowering the *pK* of the group required in the base form and raising the *pK* of the group required in the acid form[9a]. It can be seen from Table 1 that $pK_{a'}$ is greater than pK_a and $pK_{b'}$ is greater than pK_b; that is, the *pK* values of the groups at the active site are both greater in the enzyme-substrate complex than in the free enzyme: after binding the substrate, both

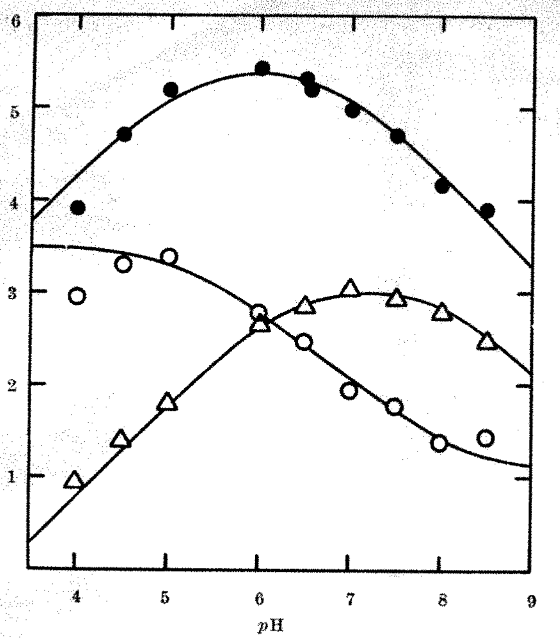

Fig. 1. Variation with pH of the kinetic parameters for the hydrolysis of cytidine 2′ : 3′-phosphate by ribonuclease at 25° C. and ionic strength 0·20. The points shown are experimental and the lines are calculated using the results in Table 1. ●—●—●, log k_3/K_m; △—△—△, log k_3; ○—○—○, pK_m

groups become weaker acids. This is evidence that the base group does not interact with the cyclic phosphate since its pK shifts in the wrong direction on formation of the enzyme-substrate complex. Binding at only the acid site would normally require $K_{a'}$ to be zero, since ES could not exist. A positive value of $K_{a'}$ indicates that, in addition to binding at the acid site, interaction occurs with one or more groups on the protein which do not change their states of ionization over the pH-range used (4–8·5). This interaction might well involve the pyrimidine ring and consequently partially determine the specificity. It is suggested that the base site is required to interact with the other reactant, water or an alcohol, in the hydrolysis, or alcoholysis, of cytidine 2′ : 3′-phosphate. Evidence for the existence of such a 'water-binding' site has already been presented[11], and other data consistent with this interpretation have recently been obtained (Findlay, D., unpublished work).

Investigation of the effects of organic solvents on the pH activity curve shows that the groups with dissociation constants $K_{b'}$ and $K_{a'}$ are cationic acids (Findlay, D., unpublished work). In these experiments the pH activity curve was determined, under conditions in which the substrate did not limit the rate, in water, 50 per cent v/v aqueous dioxane and 50 per cent v/v aqueous formamide. The difficulties of measuring and interpreting the pH of mixed solvents were circumvented by determining the three pH activity curves in buffers of two different types of charge: (a) cationic acids, $HR^+ = H^+ + R$; (b) neutral acids, $HR = H^+ + R^-$. The pK's of acids of type (a) decrease slightly in the presence of organic solvents, whereas those of type (b) increase considerably[12]. The pH activity curve shifts on addition of organic solvents with buffers of type (b) (Fig. 2), but scarcely at all in buffers of type (a) (Fig. 3). Since under the conditions employed the enzyme is saturated with substrate, any changes caused by the organic solvents are probably not due to changes in the binding constant of the substrate, but to changes in the pK's of buffers and enzyme-substrate complex. Both dissociations from the enzyme-substrate complex behave in the same way as buffers of type (a) and very differently from buffers of type (b). This confirms that they are probably both cationic acids. A detailed discussion of this problem will be presented elsewhere.

Further details of the nature of the active site has been obtained by spectrophotometric investigations[13]. Cytidine 2′-phosphate and cytidine 3′-phosphate are both competitive inhibitors of the hydrolysis of cytidine 2′ : 3′-phosphate (ref. 14 and Herries, D. G., and Ross, C. A., unpublished work), and both form complexes with the enzyme which may be

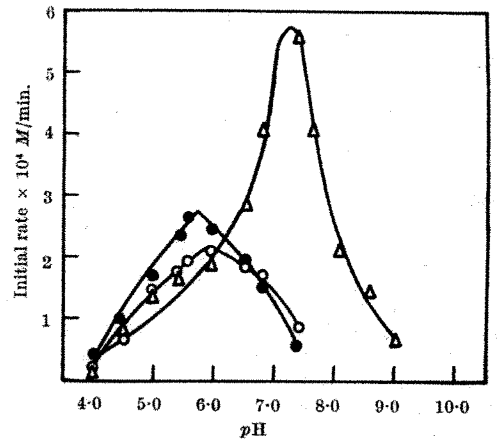

Fig. 2. Effect of solvents on the pH activity curve of the hydrolysis of cytidine 2′ : 3′-phosphate by ribonuclease in 'neutral acid' buffers at 25° C. and ionic strength 0·25. The abscissa is the pH of the appropriate buffer/salt mixture in water. The solvents used were: △—△—△, water; ●—●—●, 50 per cent v/v dioxane; ○—○—○, 50 per cent v/v formamide. The concentrations of enzyme and substrate were, respectively, 0·05 M and 0·0125 mgm./ml. The following buffers were used: pH's 4·00, 4·52, 4·99 and 5·39, acetate; pH's 5·56, 5·96 and 6·53, maleate; pH's 6·82 and 7·40, pentane 3,3-dicarboxylate (pK_2); pH's 7·65, 7·87, 8·08, 8·59 and 9·05, p-phenolsulphonate

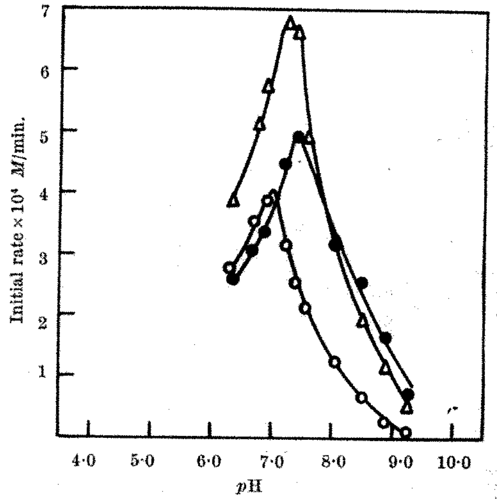

Fig. 3. Effect of solvents on the pH activity curve of the hydrolysis of cytidine 2′ : 3′-phosphate by ribonuclease in 'cationic acid' buffers at 25° C. and ionic strength 0·25. The abscissa is the pH of the appropriate buffer/salt mixture in water. The solvents used were: △—△—△, water; ●—●—●, 50 per cent v/v dioxane; ○—○—○, 50 per cent v/v formamide. The concentrations of enzyme and substrate were, respectively, 0·05 M and 0·0125 mgm./ml. The buffers used were: pH's 6·38, 6·75, 6·91, 7·23 and 7·35, ethylenediamine (pK_1); pH's 7·60, 8·10 and 8·53, N-ethylmorpholine; pH's 8·92 and 9·30, ethylenediamine (pK_2)

detected spectrophotometrically, as shown in Figs. 4 and 5. The computed spectra in these figures were obtained by assuming additivity of the absorbancies of the components, and they differ significantly from the measured spectra. This indicates formation of a complex. Alkylation of histidine residue 119 by bromoacetic acid by the method of Barnard and Stein[6a], to produce enzymically inactive CMRNase, does not alter the enzyme-inhibitor interactions as judged by the spectrophotometric shifts[13b]. Moreover, a clear-cut interaction between the substrate cytidine 2′ : 3′-phosphate and CMRNase can be demonstrated spectrophotometrically as shown in Fig. 6. This suggests that residue 119 does not interact directly with cytidine 2′ : 3′-phosphate but is the water-binding site proposed by Findlay, Mathias and Rabin[11]. Kinetic data suggest that inhibition of RNase by zinc ions[15] is associated with the formation of a ternary complex of RNase, zinc (II) and cytidine 3′-phosphate, the product of the reaction. This ternary complex can be observed spectrophotometrically (Fig. 5), but does not form with CMRNase, zinc (II) and cytidine 3′-phosphate nor with RNase, zinc (II) and cytidine 2′-phosphate. This is consistent with the binding of zinc (II) to residue 119 and provides further support for the view that this residue is not involved in binding cytidine 2′ : 3′-phosphate or cytidine 3′-phosphate. It is important to note that none of the above evidence excludes the possibility that residue 119 is involved in the formation of enzyme – substrate complexes of esters of cytidine 3′-phosphate.

monophosphates. This would suggest that one of the interactions in the enzyme – substrate or enzyme – inhibitor complex is between the 2′ cytidine oxygen and a positively charged acid-group on the protein. Of the three cytidine monophosphates, cytidine 2′-phosphate has the most basic oxygen in the 2′ position.

RNase catalyses two reactions[16] shown in Figs. 7 and 8. Both these reactions involve nucleophilic displacements about the phosphorus atom. The attacking and departing groups are, respectively: reaction 1 (Fig. 7), 2′ oxygen and OR^-; reaction II (Fig. 8), water oxygen and 2′ oxygen. The attacking reagent would be assisted by co-ordination with a base group and the removal of the departing group would be assisted by co-ordination to an acid group. Thus the acid-base requirements for reaction II are the reverse of those for reaction I in the forward direction and the same as those for reaction I in the reverse direction. We have presented evidence that both these groups are histidine residues and these are represented, in the acid form, by B_1H^+ and B_2H^+. The mechanism we suggest, in which the dotted lines are bonds being formed or broken and curved arrows the direction of electron displacements, is illustrated in Figs. 9 and 10. If ROH replaces HOH in Fig. 10, this represents the reverse of reaction I. Reaction I in the forward direction requires the species B_1H^+ and B_2; reaction II, and reaction I in the reverse direction, require B_1 and B_2H^+. This conforms with the principle of conjugate requirements[17]. B_1 is possibly residue 119 and B_2 either 48 or 105.

We are indebted to the Central Research Fund, University of London, for a grant for the purchase of automatic titration equipment and to the Wellcome Trust for a grant for the purchase of a Cary recording spectrophotometer. The following personal grants are acknowledged: Ontario Research Foundation (to D. F.); Department of Scientific and Industrial Research (to D. G. H.); Medical Research Council (to C. A. R.).

Note added in proof. Recent work from the Rockefeller Institute, New York[18], is in accord with our hypothesis of the structure of the active site of RNase. It was shown that the unique reactivity of histidine 119 towards iodoacetate is probably due to interaction of the carboxyl group of the alkylating reagent with the imidazole group, in the cationic form, of another histidine residue. The separation of the two imidazole groups required for this electrostatic enhancement is of the same order as that expected for the acid/base pair at the active site of RNase.

VISUAL PIGMENT OF GRAPSOID CRABS

By MICHAEL H. BRIGGS

Department of Chemistry, Victoria University of Wellington, New Zealand

WITHIN the past few years a number of research workers have isolated visual pigments from a variety of arthropods. Kampa[1] has extracted a pigment from the eyes of a euphausiid crustacean, *Euphausia pacifica*, while Fisher and Goldie[2] have prepared a similar photosensitive substance from the eyes of another member of this order, *Meganyctiphanes norvegica*. Wald and Hubbard[3] have extracted a pigment from the eyes of the decapod crustacean, *Homarus americanus*, and an insect visual pigment has been obtained by Goldsmith[4] from *Apis mellifera*. The first reported arachnoid visual pigment is from *Limulus*[5].

It is apparent that the arthropods offer an excellent opportunity for the study of comparative visual biochemistry[6]. The numerous arthropod species (estimated at 750,000 (ref. 7)), all possess eyes, and, moreover, present tremendous variations in nutrition, ecology, etc.—factors that probably have considerable effects on the visual mechanisms.

This article reports the extraction of visual pigments from the eyes of two species of grapsoid Crustacea. The pigments from the two species are identical, and proved to be rhodopsins of the type previously investigated by other workers from vertebrates and invertebrates[6].

The animals used were adult specimens of *Hemigrapsus edwardsii* and *Leptograpsus variegatus*, collected locally. Experiments were conducted within a few hours of capture, the animals being contained in sea-water.

In experiments to determine the vitamin A content of the eyes, the whole eyestalks were removed and immediately stored in a deep freeze until required. Visual pigments were extracted from freshly removed eyes obtained from animals previously dark-adapted for 3 hr.

Vitamin A was determined by techniques based on those of Wald and Burg[8]. The eye tissues were ground with anhydrous sodium sulphate until dry, and then repeatedly extracted with petroleum ether until the extract was colourless. A further extraction of the tissues was made with acetone to release any protein-bound carotenoids.

The petroleum ether extract was chromatographed on Merck alumina. Vitamin A esters were eluted from the column with 4 per cent acetone in petroleum ether, and free vitamin A alcohol with 40 per cent acetone in petroleum ether. Both these fractions were saponified with 6 per cent potassium hydroxide in methanol for 20 min. at 40° C., and then separately brought into solution in hexane. The absorption spectra of these solutions were determined immediately. The spectra were obtained a second time after 15-min. irradiation with sunlight in the presence of an added 5 μgm. of iodine. The vitamin A of these solutions was brought next into solution in chloroform and a Carr–Price reaction conducted by the addition of saturated antimony trichloride solution in chloroform. From the extinction coefficients of these solutions at 618 mμ the total vitamin A content was calculated.

Visual pigments were isolated from the fresh, dark-adapted eyes by techniques based on those of previous workers[1,3,5]. All stages of preparation were conducted in darkness, or with a dim photographic red light as the only source of illumination.

The eyes were thoroughly ground with a mortar and pestle, and then in a small Potter–Elvehjem glass tissue homogenizer. The ground tissues were repeatedly extracted with petroleum ether to remove light-stable pigments. The resulting tissues were extracted with a small volume of 2 per cent aqueous digitonin, and the extract filtered through sintered glass. The absorption spectrum of this solution was determined immediately, and again after 30 min. in darkness at room temperature. The solution was next exposed to sunlight for 20 min. and the absorption spectrum again determined in the presence of 0·1 *M* hydroxylamine. A difference spectrum was obtained by subtracting the optical density readings of the bleached solution from those of the unbleached solution.

To a portion of the unbleached extract acetone was added and the mixture shaken with ethyl ether. The ether fraction was separated, dried and the residue taken up in chloroform. The absorption spectrum of this extract was determined alone, and again after a Carr–Price reaction.

Extracts of the eyes of both species contained free vitamin A alcohol and vitamin A esters. Astaxanthin and other carotenoids, probably xanthophyll and beta-carotene, were also present. The total vitamin A content of the eye extracts was calculated on the basis that the extinction coefficient, E (1 per cent. 1 cm.), of the vitamin A–antimony trichloride product in chloroform is 4,400 at 618 mμ [9]. The values calculated by taking the means of several determinations are given in Table 1. These levels are comparable with the vitamin A contents reported for other crustacean species[10–14].

Table 1. VITAMIN A IN THE EYES OF GRAPSOID CRABS

	Hemigrapsus edwardsii	*Leptograpsus variegatus*
Total vitamin A (μgm. per eye)	1·3	1·5
Free vitamin A alcohol (per cent of total)	15	11
Esterified vitamin A (per cent of total)	85	89

The addition of iodine and exposure to white light of the solutions containing the extracted vitamin A led to an easily detected increase in extinction around 325 mμ. Moreover, the absorption maximum of the vitamin A in the chromatographed extracts was at 319–321 mμ before this treatment, and at 325–326 mμ afterwards. As the concentration of vitamin A in the extracts was known from the Carr–Price reactions, it was possible to calculate the extinction coefficients (E). The average E (1 per cent, 1 cm.) for all the extracts containing vitamin A (including those derived from the ester forms by saponification) was 1,225, the range of the samples being 1,210–1,255.

These results indicate that the vitamin A from the eyes of these crabs is present largely in the neo-*b* form (the 11-mono-*cis* isomer). This is the only vitamin A isomer to give a large change in extinction on exposure to iodine and sunlight, to have a $\lambda_{\max.}$ at 319–321 mμ, and to have an extinction coefficient at 320 mμ of approximately 1,200 (ref. 8). This deduction was confirmed by measuring the ratio of $E_{\max.}$ of the original extracts at 320 mμ to the $E_{\max.}$ at 325 mμ of the solutions after isomerization. The calculated ratios ranged from 1·44 to 1·50, with a mean of 1·47. The ratio for neo-*b* vitamin A is 1·45 ± 0·05 (ref. 8).

Visual pigments were successfully isolated from the ground eyes of both species by digitonin extraction. The difference spectra of these pigments from both species were identical within experimental errors. The result of a typical determination is given in Fig. 1. The photosensitive pigment has an absorption maximum at 513 ± 2 mμ. No change in spectrum was detected after the pigment solutions had been kept at room temperature for 30 min.

Examination of the spectrum of the products produced by the bleaching of the crab rhodopsin revealed the presence of a second pigment with $\lambda_{\max.}$ 495 mμ. This pigment appears to be in many ways analogous to the metarhodopsin obtained by Wald and Hubbard[3] from the lobster. On standing in the dark, the crab metarhodopsin is gradually converted to a mixture of retinene and opsin. This change is demonstrated by the slow decline in intensity of absorption at 495 mμ, and by the increased quantity of retinene extractable from the solution. The conversion of crab metarhodopsin to retinene and opsin is complete within 2 hr.

Three compounds were identified in the ether extract of the acetone-treated, unbleached solution of crab rhodopsin. A narrow absorption due to vitamin A was detected at 325 mμ, a second absorp-

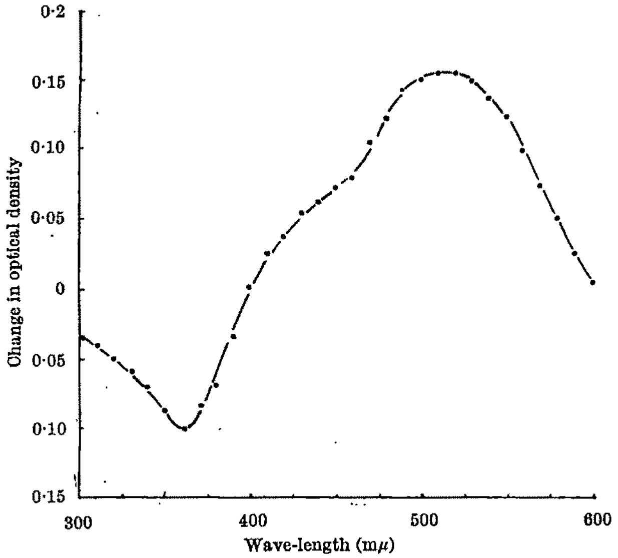

Fig. 1. Difference spectrum of rhodopsin from grapsoid crabs. Since retinene oxime has no absorption above 450 mμ, the difference spectrum is equivalent to the true absorption spectrum of the rhodopsin above this wave-length. The minimum around 362 mμ corresponds to the absorption of retinene oxime

tion at 366 mμ indicated the presence of retinene, while a broad-band absorption in the blue-green at around 470 mμ was assumed to be due to astaxanthin. The presence of vitamin A and retinene in the extract was confirmed by a Carr–Price reaction which yielded an absorption spectrum with maxima at 618 mμ (vitamin A) and at 666 mμ (retinene).

These results indicate that the digitonin extract contains a variety of compounds other than crab rhodopsin. The vitamin A detected is presumably a contaminant due to the incomplete extraction of the tissues with petroleum ether. It is unlikely to be present as a protein complex. The astaxanthin also may be a contaminant of a similar nature, but the amounts detected favour the view that the digitonin extracts an astaxanthin–protein complex from which free astaxanthin is liberated by the acetone treatment.

Considered as a whole, the above results demonstrate that crab rhodopsin is a protein with a retinene chromophore. The preponderance of neo-*b* vitamin A in the crab eyes is strong evidence that the retinene chromophore is also in the hindered 11-mono-*cis* configuration, and is thus analogous to previously isolated rhodopsins[6].

CONTRACTION OF SMOOTH MUSCLES IN NON-IONIC SOLUTIONS

By ROSELYN L. KOLODNY and PROF. W. G. VAN DER KLOOT

Department of Pharmacology, New York University School of Medicine

IT is generally assumed that muscular contraction and electrical activity depend on the presence of an extra-cellular fluid containing the ions of Ringer's solution or one of its variants. However, I. Singh *et al.*[1–3] have repeatedly reported that smooth muscles from the stomach of the frog continue to contract and to conduct action potentials when soaked in sucrose solutions. These experiments are often disregarded. Only recently, Bozler[4] confirmed the report that smooth muscles soaked in sucrose containing calcium chloride retain the ability to contract. We have repeated some of Singh's other experiments and are also able to duplicate his results.

In most of our experiments the smooth muscle of the stomach of the frog, *Rana pipiens*, was used. Strips of the stomach muscle were fastened with one end tied to a strain gauge for recording isometric tension and suspended in a simple bath. The observations were made at room temperatures. The muscles were immersed in a 0·12 *M* sucrose solution, which has about half of the tonicity of normal frog Ringer's. The sucrose was dissolved in distilled water which had been passed afterwards through a demineralizing column. The first response by the muscle to the sucrose medium is a series of large contractions. The spontaneous contractions gradually die out while the muscle undergoes a slow increase in tone. After about 2 hr. in sucrose, the muscle rarely contracts spontaneously, but contractions can be readily elicited by stimulation with $2{\cdot}9 \times 10^{-4}$ *M* epinephrine, as shown in Fig. 1*A* or with $2{\cdot}2 \times 10^{-4}$ *M* acetylcholine. The muscles continue to respond to stimulation for as long as 24 hr. after immersion in 0·12 *M* sucrose.

Muscles soaked for hours in sucrose also retain excitability to electrical stimulation. The responses fall into two general catagories. With some preparations, there is a rapid increase in the tension exerted by the muscle as soon as a d.c. stimulating current (0·05–0·6 m. amp.) begins to flow through the muscle bath; when the stimulating current is turned off, the muscle relaxes to the pre-stimulus tension. With other muscles, under the same conditions, there is little change in the tension exerted by the muscle as long as the stimulating current is flowing. But once the stimulus is turned off, there is a brief latent period and then the muscle contracts, reaches a maximum tension, and relaxes. The longer the stimulus, the shorter the latent period and the greater the contraction. The variables determining whether the muscle contracts along with, or after, electrical stimulation have not yet been resolved; perhaps the most important factor is the portion of the stomach selected as the source of the muscle strip.

In a smaller series of experiments, it was found that short lengths of the taenia coli of the guinea pig soaked for hours in 0·16 *M* sucrose remain responsive to chemical and electrical stimulation.

Singh and Acharya also reported that sucrose-soaked frog stomach muscle continues to conduct action potentials, judging from an extra-cellular recording. We have taken strips of frog stomach muscle soaked in 0·12 *M* sucrose and simultaneously recorded tension, with a strain gauge, and electrical activity between a pair of fine platinum electrodes pushed into the muscle. As shown in Fig. 1*B*, the contractions of the muscle were accompanied by a marked increase in the amount of electrical activity recorded from the muscle.

We have also begun to study conduction in isolated ureters from the guinea pig, which are ideally suited for measurements of conduction velocities. At 33° C. in Tyrode's solution the conduction velocity is about 2·5 cm./sec. After 220 min. in 0·32 *M* sucrose, the conduction velocity falls to 0·026 cm./sec., probably because the resistance of the extra-cellular fluid has markedly increased.

In a final series of experiments, fine capillary electrodes filled with 3 *M* potassium chloride were thrust into strips of frog stomach muscle which had been soaked in 0·12 *M* sucrose for 3 or more hours. The records are poor technically, owing to the high resistance of the sugar solution and of the micro-electrodes. It is striking, however, how similar the records from sucrose-soaked muscles are to those from muscles in Ringer's solution. Estimates of the 'resting' potentials are uncertain because high tip potentials are common and uncertain with such fine electrodes. The recorded values ranged between 20 and 70 mV., inside the cell negative. A section of a record is shown as Fig. 2. In only one case was a spike recorded which seemed to overshoot the zero potential baseline. Therefore, it cannot be definitely decided whether or not an action potential can overshoot when the external medium is a sucrose solution. Preliminary results show that in sucrose-soaked muscles treated with epinephrine there is an increase in the rate of spiking and a decrease in the 'resting' potential. Spiking was reversibly eliminated by chilling the sucrose solution bathing the muscle.

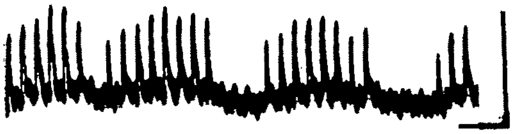

Fig. 2. A recording made with a micropipette inserted into a strip of frog stomach muscle soaked for 3 hr. in 0·12 *M* sucrose. The base line is marred by a high noise-level. Calibrations: time, 0·1 sec.; voltage, 50 mV.

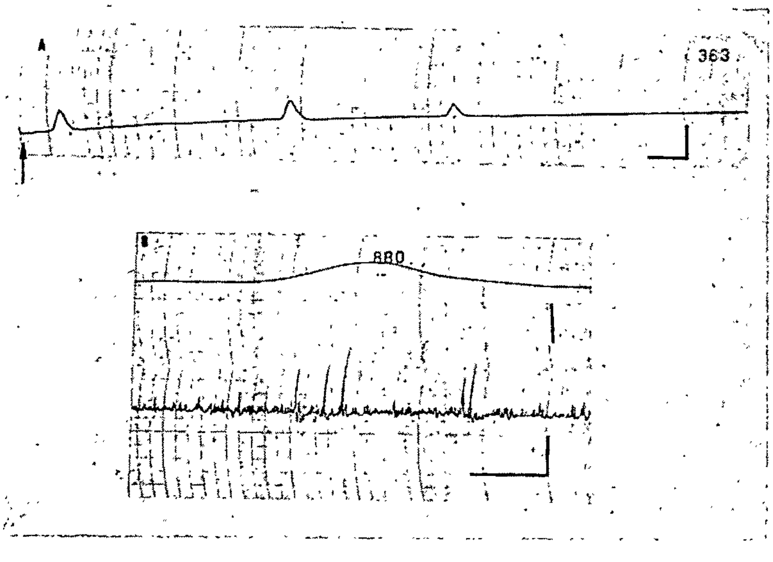

Fig. 1. *A*, response of a strip of frog stomach muscle, soaked for 3½ hr. in 0·12 *M* sucrose, to epinephrine hydrochloride (added at the arrow). Note the increase in tone and the three rhythmic contractions. Calibrations: time, 30 sec.; tension, 0·5 gm. *B*, simultaneous electrical and mechanical recordings from a strip of frog stomach muscle soaked for 3 hr. in 0·12 *M* sucrose. The record shows a spontaneous contraction and the simultaneous electrical activity. Calibrations: time, 30 sec.; tension, 0·5 gm.; voltage, 50 µV.

The principal conclusion is that the mechanical and electrical behaviour of these smooth muscles are changed relatively little when the tissue is transferred from an environment of Ringer's to a sucrose solution which is about half isotonic. This is true in spite of the change in the extra-cellular fluid and a drastic change in the inorganic composition of the tissue. In sucrose-soaked muscles, ashed and analysed by flame photometry, the concentration of sodium is about 4·5 m*M*/kgm. of muscle water and the concentration of potassium is about 45·7 m*M*/kgm. The values for the Ringer's-soaked muscles are: sodium, 66 m*M*/kgm.; potassium, 129 m*M*/kgm. (ref. 5).

Obviously these results challenge some of the present ideas about the electrical activity and the contraction of smooth muscles. Since the sodium concentration of the muscles falls during the soaking in sucrose to about 10 per cent of the initial value, there is little possibility that the extra-cellular fluid is protected by a diffusion barrier from exchanging with the external medium. Therefore, whatever ions are present in the extra-cellular fluid of a muscle soaked in sucrose must come from the impurities in the reagent grade sucrose, from the distilled and demineralized water, or by leaching from the muscle cells. Although we cannot as yet place a precise upper limit on the concentration of ions in the extra-cellular fluid of the sucrose-soaked muscles, it must be extremely low compared with the normal environment of the cells. Holman[6] showed that the electrical activity of smooth muscles does not depend on the sodium concentration of the external medium in the way that is familiar with nerve and with skeletal muscle. However, it is still surprising to see electrical signals which look very similar to the normal action potentials occurring when the extra-cellular fluid can contain only a fraction of a millimole of sodium.

The continued contraction by sucrose-soaked smooth muscles is equally surprising. Axelsson and

Bülbring[7] showed that the removal of calcium from Ringer's solution led to the loss of tension by the taenia coli, and Robertson[8] showed that the mechanical response of smooth muscles (depolarized in potassium sulphate-Ringer's and stimulated with acetylcholine) declined markedly when calcium was withdrawn from the medium. These experiments were interpreted as showing that extra-cellular calcium is needed for contraction. The concentration of calcium in the extra-cellular fluid is unlikely to be markedly greater in a muscle soaked for many hours in 0·12 *M* sucrose than in a muscle soaked for a shorter time in a calcium-free Ringer's. Nevertheless, the sucrose-soaked muscles can contract. It appears that ionic solutions which do not contain calcium may stop smooth muscles from contracting—perhaps by displacing a critical fraction of the calcium from the cell. However, from the evidence now at hand it cannot be concluded that the contraction of smooth muscles depends on the presence of calcium in the extra-cellular fluid.

It is also remarkable to find continued electrical and mechanical activity, supported by the metabolism of the cells, coming from a tissue the intracellular ionic composition of which must be changed so drastically.

In summary, we have confirmed the observations by Singh *et al.* that smooth muscles soaked in half-isotonic sucrose solutions retain electrical activity and contractility. The behaviour of 'slow' skeletal muscle fibres in sucrose is different from that of smooth muscles; acetylcholine, which normally produces depolarization and contraction, causes sucrose-soaked frog recti to become hyperpolarized and to relax[9].

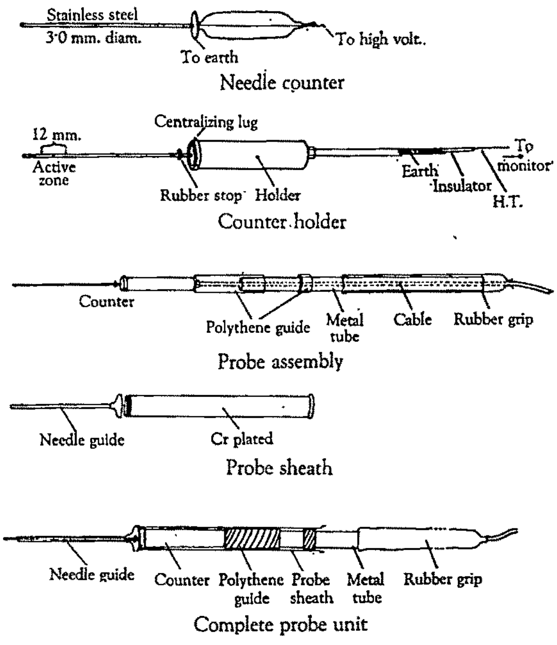
MOVEMENT OF THE OVUM IN THE REPRODUCTIVE TRACT

A Needle Probe Geiger-Müller Counter for the Study of the Passage of the Ovum in the Reproductive Tract

In an endeavour to inquire into the reasons for the failure of non-surgical transfers of ova into recipient cows[1], small radioactive spheres[2], the passage of which in the reproductive tract could be traced with a newly designed probe unit, were used to simulate cow ova. The 'artificial ova', consisting of an ion exchange resin ('Permutit'), impregnated with radioactive gold, gold-198, of density 1·2 and 120μ in diameter, were transferred to the cow uterus via the cervix. They were suspended in a small quantity of cow serum delivered from a syringe attached to a narrow metal tube extending into the uterine horn. The needle probe apparatus was then used to search the internal walls of the uterine horns, cervix and vagina for the presence of the radioactive artificial ova at varying intervals of time after transfer. A report of the results of this investigation forms the subject of the next communication. The gold-198 spheres are also being used in some other work on the tubal transport of ova in the rabbit[2] and in the ewe[3].

The essential part of the needle probe apparatus (Fig. 1) is the stainless steel *NIb* needle counter (20th Century Electronics), contained in a chromium plated counter holder. The needle counter itself is 150 mm. long and the active length of the Geiger–Müller counter is 12 mm., situated 7 mm. from the tip of the needle. The probe assembly consists of the counter holder bolted on to a hollow polythene guide of length 58 mm. and outside diameter 34 mm., utilizing the earthing nut at the rear of the holder. Into this guide is inserted a thin-walled aluminium metal tube of 25 mm. outside diameter. A further polythene guide 15 mm. long is situated 5 cm. behind the first. The rear part of the aluminium tube is covered with a rubber sheath handle, through which the high-tension cable passes out to a rate-meter which measures any radioactivity detected. The whole of the probe assembly as shown in Fig. 1 is inserted into a chromium plated probe sheath 34 cm. long with an outside diameter of 3·8 cm. Part of the probe sheath consists of a detachable blunt-ended needle guide, 12·5 cm. long and 4·0 mm. outside diameter, screwed on to the end. The needle of the counter is directed into the needle guide by means of three centralizing lugs on the counter holder, and by the polythene guides on the probe assembly.



Needle counter

Counter holder

Probe assembly

Probe sheath

Complete probe unit

Fig. 1. Needle probe equipment

In order to search the cow reproductive tract for any radioactivity emitted from the gold-198 spheres, the complete probe unit (Fig. 1) is grasped in one hand by means of the rubber handle of the probe assembly. The other hand is inserted into the rectum of the cow to help guide the needle through the cervix and into the uterine horns. A little 'Vaseline' on the outside of the probe sheath is sometimes needed to ease the probe sheath up the vaginal tract. With the needle retracted into the needle guide, the complete probe unit is inserted and the needle guide passed through the cervix into the uterus of the cow. The counter is then eased forward up the probe sheath by applying forward pressure on the rubber grip with the free hand. The needle slides out from the guide, exposing the active counting zone to any radiation present in the near vicinity. The intensity of radiation present is measured on the rate-meter. It was found possible to estimate very rapidly the approximate number of gold-198 spheres in the uterus or the vagina merely by judging the noise emitted by the loudspeaker in the rate-meter. The vagina was always searched for radioactivity before investigating the cervix and uterus. This ensured that any radioactivity detected in the vagina was not due to gold-198 spheres which might be dislodged from the uterus during manipulation of the needle guide through the cervix.
